As Required By the Veterans Access, Choice, and Accountability
Act of 2014
Section 201

Independent Assessment of the Health Care Delivery Systems and Management Processes of the Department of Veterans Affairs

Volume I: Integrated Report

This page intentionally left blank.

Preface

Congress enacted and President Obama signed into law the Veterans Access, Choice, and Accountability Act of 2014 (Public Law 113-146) ("Veterans Choice Act"), as amended by the Department of Veterans Affairs (VA) Expiring Authorities Act of 2014 (Public Law 113-175), to improve access to timely, high-quality health care for Veterans. Under "Title II – Health Care Administrative Matters," Section 201 calls for an Independent Assessment of 12 areas of VA's health care delivery systems and management processes.

VA engaged the Institute of Medicine of the National Academies to prepare an assessment of access standards and engaged the Centers for Medicare & Medicaid Services (CMS) Alliance to Modernize Healthcare (CAMH)[1] to serve as the program integrator and as primary developer of the remaining 11 Veterans Choice Act independent assessments. CAMH subcontracted with Grant Thornton LLP, McKinsey & Company, and the RAND Corporation to conduct 10 independent assessments as specified in Section 201, with MITRE conducting the 11th assessment. Drawing on the results of the 12 assessments, CAMH also produced the Integrated Report in this volume, which contains key findings and recommendations. CAMH is furnishing the complete set of reports to the Secretary of Veterans Affairs, the Committee on Veterans' Affairs of the Senate, the Committee on Veterans' Affairs of the House of Representatives, and the Commission on Care.

---

[1] The CMS Alliance to Modernize Healthcare (CAMH), sponsored by the Centers for Medicare & Medicaid Services (CMS), is a federally funded research and development center (FFRDC) operated by The MITRE Corporation, a not-for-profit company chartered to work in the public interest. For additional information, see the CMS Alliance to Modernize Healthcare (CAMH) website (http://www.mitre.org/centers/cms-alliances-to-modernize-healthcare/who-we-are/the-camh-difference).

Acknowledgments

Conducting this assessment on behalf of our nation's Veterans has been an honor. A common theme emerged as we explored data, interviewed staff, reviewed prior assessments, and assembled this report—Americans take the care of our Veterans seriously.

We would like to acknowledge those who have enabled us to complete this assessment, which carries the promise of improving Veterans health care.

First and foremost, we want to thank the leadership and staff of the Department of Veterans Affairs (VA) who routinely and unselfishly shared their time, insights, perspectives, and data. Our assessment teams visited 87 Veterans Health Administration facilities, including VA Medical Centers, Veterans Integrated Service Network headquarters, acquisition centers, construction and facilities management offices, and pharmacies, where we observed staff working diligently to provide the best possible clinical care to Veterans. During these visits, assessment teams conducted multiple interviews of VA employees, including providers, clinicians, administrators, and senior leaders. VA also provided 560 requested data sets.

Second, we are grateful to the Blue Ribbon Panel members who served as our advisers. This panel brought together individuals with years of experience in successfully transforming and running health care systems. We turned to these experts for advice and to determine if our ideas were aligned with current industry wisdom and emerging health care trends. The panel meticulously examined the materials we presented, applied their experience and industry knowledge, and shared candid recommendations. They are identified in Appendix Q.

Third, we appreciate the support of the Veterans Service Organizations (VSOs) listed in Appendix M that shared their data, reports, and surveys and their understanding of their constituents' health care needs. They provided the invaluable "Voice of the Veteran."

Fourth, we engaged with U.S. health care industry leaders who gave their time and provided access to their organizations and senior leadership teams. They shared their experience, perspectives, health initiatives, and viewpoints of best practices in health care that could be adopted by the Veterans health care system. Several also supported on-site visits to examine their clinical and administrative operations. These organizations are listed in Appendix M.

Finally, on behalf of the CMS Alliance to Modernize Healthcare, we would like to thank the team members from The MITRE Corporation, McKinsey & Company, RAND Corporation, Grant Thornton LLP, the Institute of Medicine of the National Academies, and numerous smaller companies and consultants who dedicated their time and energy to gather data, conduct analyses, and develop the materials that have been assembled in these Assessments and the Integrated Report. Throughout the process, it was clear that every team member shared a common commitment—to improve the health care for Veterans "who shall have borne the battle."[2]

September 1, 2015

The Honorable Robert A. McDonald
Secretary
U.S. Department of Veterans Affairs
810 Vermont Avenue, N.W.
Washington, D.C. 20420-0002

Dear Secretary McDonald:

To support the Independent Assessment required by Section 201 of the Veterans Choice Act, The MITRE Corporation created a Blue Ribbon Panel, composed of experts from diverse health care and stakeholder backgrounds, to fully engage with MITRE in producing the Integrated Report and its findings and recommendations. Although the Panel was not specifically required by the Veterans Choice Act, we were fully involved by MITRE from the onset of the study, with complete access to raw data, subcontractor consulting teams, and MITRE subject matter experts and senior management.

MITRE assured the Panel of our complete independence, meaning that there would be full disclosure of data and assessments; that the Panel could meet in executive session as often as necessary; that the Panel would provide candid feedback and advice on the final findings and recommendations submitted by MITRE; and that the Panel was under no obligation to endorse the final Integrated Report. In addition, following public submission of the report to Congress and the VA, Panel members would be free to independently express their personal opinions regarding the process or findings, while protecting the confidentiality and propriety of the information.

With independence and transparency, the Panel pursued this study with extraordinary energy and commitment, because we—like everyone involved—were passionate about improving the health and quality of care for our Veterans. Over the past months, we reviewed thousands of pages of drafts, engaged in numerous conference calls, and spent four 2-day sessions in lively meetings at MITRE headquarters near Washington, D.C. We facilitated data collection, provided frequent and timely feedback, and worked collaboratively with MITRE to develop final priorities and recommendations. MITRE was consistently responsive to the Panel, and incorporated our advice at all stages.

Now, we the members of the Panel unanimously endorse the Integrated Report and its findings and recommendations. The report provides not only operational, near-term strategies to improve clinical care for Veterans, but also details remedies for root-cause problems that must be addressed both by Congress and the VA before any long term, sustained improvement can be realized. Among these root issues are the need to prospectively and clearly define the role of the VHA within the modern health care ecosystem, including whether the VHA should become a comprehensive health care system for all health needs, or focus on specific areas of service-related conditions. In addition, the Congress and the VA must solve the VHA crises in leadership and culture, establish and empower the governance structure, and provide the VHA with core tools essential for any modern continuously-improving, value-based, health care system.

Finally, the Panel would like to express our appreciation to the hundreds of experts who have contributed to this report, and to the literally thousands of contributing Veterans and VHA employees who believed that this report would become a roadmap to achieve the highest quality of care for Veterans, at a cost we can afford, and in a culture that would be the envy of any health care system in the nation.

Sincerely,

Executive Summary

Background: Section 201 of the Veterans Access, Choice, and Accountability Act of 2014 required an Independent Assessment of the hospital care, medical services, and other health care furnished in medical facilities of the Department of Veterans Affairs (VA). The Act specifically directed that assessments be conducted in 12 areas, covering a broad spectrum of Veterans Health Administration (VHA) services, operations, and support (Figure ES-1). The findings and recommendations from these assessments revealed interrelationships that demand a holistic understanding of VHA.

VHA's health care delivery system is challenged by a unique combination of factors including its significant scale and scope, unique patient population, and congressionally mandated funding, governance, and oversight. VHA operates one of the country's largest and most complex organizations, with 1,600 care sites (including 167 medical centers) across 50 states, currently staffed by approximately 300,000 employees who cared for nearly six million Veterans last fiscal year. VHA is a major research and teaching organization, with a $1.2 billion annual research budget. Its health professional education program is the nation's largest, clinically training nearly 120,000 individuals each year via affiliations with more than 1,800 educational institutions.

L. Leadership

Approach: The Independent Assessment was performed by interviewing VA employees and outside observers, visiting 87 VA sites, conducting multiple surveys, analyzing 560 data sets provided by VHA and data from other sources, and performing literature reviews. In addition, best practices were gathered from the private sector through interviews with top health care executives, site visits to high-performing health care organizations, and consultation with an independent advisory panel of nationally recognized health executives and stakeholders (Appendix Q: Blue Ribbon Panel). This approach not only provided deep understanding of the 12 assessment areas, but additionally provided a comprehensive view of VHA. It is VHA's interdependent system that is the focus of the findings and recommendations in the Integrated Report.

The Independent Assessment: The Independent Assessment includes this Integrated Report and the 12 major assessment reports for the areas designated in ES-1. Each area is addressed in a separate assessment report that includes findings and evidence-based recommendations (Appendices A–L and Volume II). The Integrated Report builds upon the findings and recommendations of those reports and identifies the four systemic findings that must be addressed to enable a sustained transformation of VHA.

Significant Flaws: While VHA exhibits a deep commitment to serving Veterans, many of the assessment teams consistently found that VHA's health care facilities deliver strikingly different patient experiences, apply inconsistent business processes, and differ widely on key measures of performance and efficiency. The assessments also provided evidence that the organization is plagued by many problems: growing bureaucracy, leadership and staffing challenges, and an unsustainable trajectory of capital costs. Other reports and assessments have pointed to local failures of access and quality. On the other hand, there are bright spots throughout VHA that illuminate best practices that work effectively within the VHA environment. Understanding the various aspects of these differences sets a context that can allow VHA to identify and act on opportunities for continuous sustained improvement.

Systems Approach: VHA must adopt systems thinking to address its most challenging problems, including access, quality, cost, and patient experience.[3] Systems thinking is a framework for solving problems based on the premise that a component part of an entity can best be understood in the context of its relationships with the other components of the entity, rather than in isolation. It takes into account the interdependencies of the parts to find the best combination of strategies that meet the needs of the whole. This approach is required to address the interdependent nature of the people, processes, and technologies supporting VHA. This approach has been well established in many industries, including health care, and often enables leaders to reframe the problem into opportunities based on an appreciation of how components of the program should be working together, as opposed to how they are currently interacting. Systems thinking does not promote tackling individual problems independently because the solutions—more often than not—will be sub-optimal, non-scalable, and non-sustainable.

While complex problems benefit greatly by reframing problems in creative ways, systems solutions also work well for improving existing processes and motivating people to believe they can successfully change. Continuous improvement is one such approach that often uses a Plan-Do-Study-Act cycle that identifies, reduces, and eliminates suboptimal processes for continuous incremental or breakthrough improvements. This approach relies heavily on measuring, analyzing, and experimenting for successful innovations. The current culture in VHA would benefit greatly from instituting continuous improvement more effectively so that everyone participates, sees progress, and can build on the pride they have in being part of VHA. Some of VHA's best performers already focus on continuous improvement, but it is not widely adopted as a standard way of operating. Transforming any organization, especially one the size of VHA, requires that everyone understands, feels accountable for, and acts daily on how to continuously improve the organization. It is as much about engaging the people as it is about fixing the processes.

Four Systemic Findings: A review of the extensive evidence, findings, and recommendations in the assessment reports—informed by an analysis of industry benchmarks and best practices, insights from health care executives and high-performing health care systems, and interactions

---

[3] This information is informed by the Institute of Medicine Assessment D (Access Standards) in Volume II.

with Veterans Service Organizations—enabled the identification of four systemic findings that impact mission execution.

- A disconnect in the alignment of demand, resources, and authorities
- Uneven bureaucratic operations and processes
- Non-integrated variations in clinical and business data and tools
- Leaders are not fully empowered due to a lack of clear authority, priorities, and goals.

The recommendations that will enable VHA to address these findings are discussed below. These recommendations are interdependent and must be coordinated and implemented via a systems approach to improve the VHA system overall.

Finding 1: A disconnect in the alignment of demand, resources, and authorities

VHA's mission—"Honor America's Veterans by providing exceptional health care that improves their health and well-being"[4]—is inspirational and widely accepted by VHA staff, but there are significant geographic variations with respect to how the mission is translated into action for individual Veterans. Complex eligibility rules make determining which Veterans are covered and which services those Veterans receive a challenge, and navigating VHA is often difficult for Veterans—a problem exacerbated by incomplete guidance and non-standardized business processes. Furthermore, the growing role of outside providers has not been effectively integrated into VHA's operating model, which is based on providing direct care within VHA facilities.

At present, VHA is over-committed in some geographic areas, given its broad mission, an expanding list of automatic eligibility criteria, and limited resources. Matching supply and demand at the local level is challenging because supply is relatively fixed each year once service projection models allocate resources to each facility through the appropriation and budgeting process.

Although the population of Veterans is expected to decline by 19 percent over the next decade,[5] the demand for health care services is expected to rise before it levels off in five years, based on demographic factors (primarily aging)—and likely will rise even more if access to VHA health care is improved (Assessment B [Health Care Capabilities]). On the other hand, in some areas and for some health conditions, VHA may not have a sufficient population of patients to sustain highly specialized service lines with enough volume to achieve and maintain clinical excellence.

Recommendation 1—GOVERNANCE: Align demand, resources, and authorities.

Congress, the Commission on Care, and VA leadership should address the misalignment of demand with available resources both overall and locally. They should align VHA's goal to

---

[5] This information is presented in RAND Corporation Assessment A (Demographics) in Volume II.

provide comprehensive health care to Veterans with VHA's capacity by adjusting capacity or reshaping the expected benefit—that is, the Veteran population to be served (eligibility) on the one hand, and the health care those Veterans will be provided (service lines) both by VHA and by community resources on the other.

Supporting Recommendations

- **Establish a governance board to develop fundamental policy, define the strategic path, insulate VHA leadership from direct political interaction, and ensure accountability for the achievement of established performance measures.**
  Congress should consider the following alternatives for such a governance board:
  - Charter a commission modeled after the 1955 U.S. President's Commission on Veterans' Pensions.
  - Empower a board or commission to reshape geographic service areas and optimize facilities resourcing and lines of service (along the lines of the Defense Base Realignment and Closure Commission process used for military installations).
  - Assign the definition of the governance board as a mission for the Commission on Care, established under Section 202 of the Veterans Choice Act.
  - Whatever approach is selected, ensure that the solution focuses on governance, that members have sufficient longevity of term, and that the authorities of the board are fully endorsed by Congress.

- **Require a patient-centered demand model that forecasts resources needed by geographic location to improve access and to make informed resourcing decisions.**
  VHA should:
  - Effectively explore predictive tools to continually forecast local demand and fine-tune estimates of required resources.
  - Reallocate and manage resources flexibly to meet national, regional, and local variations in patient-centered demand.

- **Clarify and simplify the rules for purchased care to provide the best value for patients.[6]**
  VHA should:
  - Develop a stronger management structure for purchased care and allocate responsibility and authority to the most appropriate levels.
  - Establish an ongoing process for evaluating third-party administrator performance.
  - Develop clear and consistent guidance and training on VA's authority to purchase care.
  - Ensure that both new and existing purchased care contracts with outside providers and third-party administrators include appropriate requirements for data sharing, quality-of-care reporting, and care coordination.

---

[6] This information is derived from RAND Corporation Assessment C (Care Authorities) in Volume II.

Finding 2—Uneven bureaucratic operations and processes

Several centralized operational and support functions appear to have lost customer focus and do not adequately support the needs of the medical centers. In response, individual VA Medical Centers (VAMCs) have adopted local implementations of certain processes, but many of these were found to be unnecessarily complex and, not surprisingly, inconsistent across VHA. In many cases, these centralized and local process issues have become inefficient or bureaucratic and have had a direct and negative impact on the overall Veteran experience and timely access to care.

These widely varying processes highlight the complexity of VHA within the larger, equally complex VA organization. Severe problems may manifest themselves at one facility, while another constantly receives tributes from Veterans and health care experts. The oft-quoted reminder, "if you've seen one VA hospital, you've seen ONE VA hospital," captures this reality.

Recommendation 2—OPERATIONS: Develop a patient-centered operations model that balances local autonomy with appropriate standardization and employs best practices for high-quality health care.

As Assessment L (Leadership) suggests, VA and VHA should streamline their Central Offices and strengthen poor-performing support functions. VHA should adopt systemic means to identify, assess, disseminate, adapt, and scale best practices throughout the system—whether these practices originate inside or outside of VHA.

Supporting Recommendations

- **Right size and reorient the VHA Central Office to focus on support to the field in its delivery of care to Veterans.** This implies a series of actions to include reassessing all VHA Central Office-directed metrics and policies to ensure that they add sufficient value to patient outcomes and eliminate those that do not.

- **Fix substandard processes that impede the quality of care provided to the Veteran.** This is clearly dependent on, among other efforts, implementing an operating model that provides medical centers with the autonomy and flexibility to innovate and address local needs while also providing standardization across the system.

- **Design and implement a systematic approach to identify best practices and disseminate them appropriately across the enterprise.** This approach would include defining the role of the Veterans Integrated Service Network (VISN) to lead the best-practice identification and to share ideas within and across the enterprise, working collaboratively with VAMC leaders and staff.

Finding 3—Non-integrated variations in clinical and business data and tools

A lack of common, integrated VHA enterprise systems and tools negatively impacts VHA's operations and resulting data. Inconsistent and ineffective data collection and analysis undermines rapid, evidence-based assessment and improvement of quality and customer satisfaction. VHA lacks a holistic, enterprise approach to collecting and leveraging its data. Data interchange with the Department of Defense (DoD) and external health care providers is

limited, which creates unnecessary clinical risk. Since newly discharged Veterans often become VA patients, interoperability with DoD is necessary and expected. These shortfalls hinder using available data to support effective decision making and performance management.

Recommendation 3—DATA AND TOOLS: Develop and deploy a standardized and common set of data and tools for transparency, learning, and evidence-based decisions.

Supporting Recommendations

- **Use standardized clinical and administrative data for accuracy and interoperability.**

- **Implement a single, integrated set of system-wide tools centered on a common electronic health record (EHR) that is interoperable across VHA and with DoD and community providers.[7]**
  Specifically, VHA should implement and integrate one system-wide:
  - EHR system that is interoperable across the entire system and with DoD and community providers
  - Electronic claims payment system to pay for outside services
  - Billing system to collect from other payers
  - Patient-friendly scheduling system with modern, single toll-free-number call-center support
  - Set of electronic clinical decision-support tools describing standard work, protocols, and guidelines housed in an electronic medical library.

- **Transparently share performance metrics for leadership, clinical, and business functions across VHA to identify and adopt best practices for continuous improvement.**

Finding 4—Leaders are not fully empowered due to a lack of clear authority, priorities, and goals

As Assessment L indicates, VHA leaders operate within a challenging and disempowering environment that discourages emerging leaders from seeking promotion within the organization. While VHA has seen a 160-percent growth in headquarters program office staff in the past five years, key field leadership positions throughout the organization sit vacant or are staffed with acting leaders, and more than half of executives are eligible for retirement, potentially creating a larger number of vacant positions. Further, a misalignment of accountability and authority exists within a broader VHA culture characterized by risk aversion and lack of trust. Those leaders who are effective too often achieve outcomes despite the challenges of the organization within which they operate.

---

[7] This information is derived from The MITRE Corporation Assessment H (Health Information Technology) in Volume II.

Recommendation 4—LEADERSHIP: Stabilize, grow, and empower leaders; galvanize them around clear priorities; and build a healthy culture of collaboration, ownership, and accountability.[8]

VHA must resolve the leadership crisis by putting the right leaders in the right jobs with the right skills under an appropriate governance model for the appropriate amount of time.

Supporting Recommendations

- **Push decision rights, authorities, and responsibilities to the lowest appropriate level throughout the organization.**

- **Build on Veteran-centered behaviors to drive a culture of service excellence, trust, continuous improvement, and healthy accountability.**

- **Revitalize the leadership pipeline through establishment of enterprise-wide, comprehensive succession-management and leadership-development functions.**

- **Strengthen the appeal of senior leadership positions by pursuing flexibilities in hiring and compensation.**

- **Establish sustained leadership continuity by extending tenure for key positions.**

A Call for System-Wide Change: The Independent Assessment highlighted systemic, critical problems and confirmed the need for change that has been voiced by Veterans and their families, the American public, Congress, and VHA staff. Solving these problems will demand far-reaching and complex changes that, when taken together, amount to no less than a system-wide reworking of VHA.

Several high-performing health care organizations were examined by the study team, including Kaiser Permanente, Virginia Mason, Geisinger Health System, and the Cleveland Clinic. Although all of these are of a differing scale than VHA, all overcame significant clinical or economic troubles by making consistent, organization-wide changes that enabled them to transform themselves into organizations that now excel at their specific missions. Similarly, during 1994 to 1999, sustained leadership within VHA deployed system-wide changes that effected a major transformation of the agency's operations. VHA should once again commit to that level of systemic change.

A system-wide transformation is required, based on an integrated systems approach that acknowledges the interdependence of the four systems recommendations:

1) **Governance**: Align demand, resources, and authorities.
2) **Operations**: Develop a patient-centered operations model that balances local autonomy with appropriate standardization and employs best practices for high-quality health care.
3) **Data and Tools**: Develop and deploy a standardized and common set of data and tools for transparency, learning, and evidence-based decisions.

---

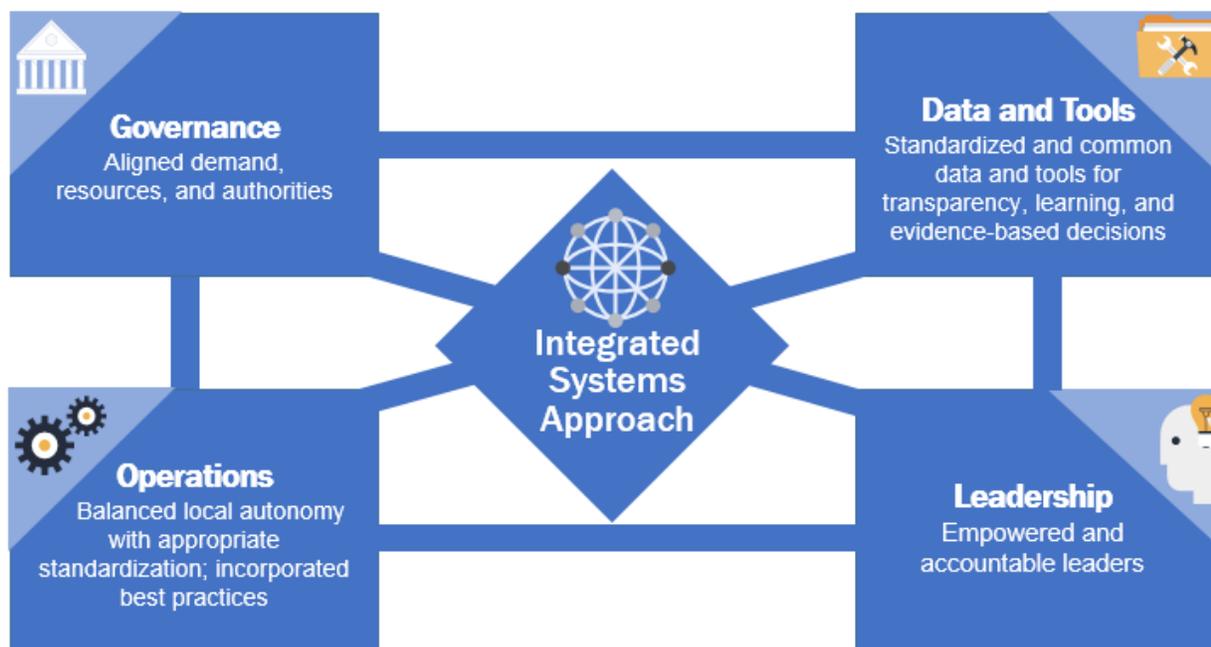
[8] This recommendation and the ideas expressed in the supporting recommendations reflect information provided in McKinsey & Company Assessment L (Leadership) in Volume II.

---

4) **Leadership**: Stabilize, grow, and empower leaders; galvanize them around clear priorities; and build a healthy culture of collaboration, ownership, and accountability.

These four recommendations create the integrated systems cornerstones, as shown in Figure ES-2.

With these four interdependent systems components successfully in place, VHA will have the opportunity to achieve a place among the highest performing health care systems in the world. As an example of the value of this systems approach, consider the challenges that VA faces in managing its capital program in facilities management. As Assessment K (Facilities) highlights, provided that average funding levels remain consistent over the next 10 years, the $51 billion capital requirement would significantly exceed the anticipated funding level of $16–26 billion.[9] Not only would this shortfall jeopardize the capital program, it would also threaten the financial integrity of the entire VHA health care delivery system and, in turn, significantly impact the quality of health care provided to Veterans. Viewing this primarily as a funding problem would be shortsighted. Rather there are interdependent findings in each of the four cornerstones that need to be addressed in an integrated fashion to achieve a sustainable solution. In terms of governance, external constraints limit VHA's ability to deliver and operate medical facilities at the level of private-sector benchmarks; investments in facilities are not effectively linked to workload growth; existing space is not being used at its highest efficiency; and expected funding levels do not support identified capital needs.

ES-2. Integrated Systems Cornerstones


As Assessment K also reveals, for operations, total cost of ownership is not calculated or integrated into capital planning decisions; VHA has no integrated system to manage the entire

---

[9] This information comes from McKinsey & Company Assessment K (Facilities) in Volume II.

leasing process; comprehensive tracking or measurement of the leasing program and its outcomes is precluded; and a large majority of facilities noted challenges in hiring staff and filling vacant positions. For data and tools, data capture occurs at multiple levels and through multiple tools, generating multiple sources of truth about the status of the capital program; tools for developing Strategic Capital Investment Plan business cases rely on user creativity and capabilities to consider creative alternatives to capital solutions; and systems do not consistently capture key performance indicators, and the metrics are not standardized across all stakeholders. And for leadership, there are recognized shortfalls in overall accountability, role clarity, personal ownership, internal communication, and proactive problem-solving approaches that limit VA's and VHA's ability to deliver the correct projects on time and on budget; the broader culture of facilities functions is characterized by silos and risk aversion, resulting in an inability to consistently advance projects in an efficient manner; and competition for limited funds has led leaders to make a range of choices in developing projects that favor approval strategies over efficient project delivery.

Viewing these facilities challenges through the lens of the integrated systems approach begins to reveal the complexity of the problem, the integrated nature of the required transformation, and the opportunity to reframe the facilities challenges as part of a larger set of interdependent pieces of VHA's overall health care system. Facility challenges can be significantly mitigated by a transformative realignment throughout the capital program deploying best practices in leasing and contracting; realigning the strategy of the capital program to improve project selection, optimize the infrastructure portfolio, implement innovative care delivery models, understand demand-based needs, and explore and partner with purchased-care opportunities; and reevaluating funding requirements. In short, employing the systems view could help reframe the vision for future health delivery and significantly reduce VHA's current and future capital investment issues. It also positions VHA not to be burdened long term with hospital overcapacity as the nature of health care delivery trends toward smaller inpatient facilities, increasing outpatient care, and more virtualized health care delivery.

The richness of the systems approach extends not just to facilities, but across many of VHA's biggest challenges. Patient access to clinician appointments cannot be sustainably addressed by only focusing on increasing overtime in the near term without looking at demand modeling, improving scheduling processes and tools, and a number of other dependencies. Choice Card funding is critical to increase purchased care access, but will not succeed without strong Veteran navigational aids, clearer rules of use, and a number of other cultural and leadership changes to promote using health care services outside of VHA. Prioritizing these findings and then solving them individually is tempting, but such an approach would not guarantee a sustainable solution. As H.L. Mencken stated, "For every complex problem there is an answer that is clear, simple, and wrong."

There are clear obstacles. As the assessment reports reveal, the number of issues VHA currently faces appears overwhelming. In its current state, VHA is not well positioned to succeed in the transformation that this analysis suggests. Three essential actions are required to realize the recommendations inherent in this transformation. VHA must:

- Recognize that the four cornerstones are interdependent and the success of any one of the four overarching recommendations hinges on the implementation of the other three. These solutions must be coordinated and implemented via a systems approach to improve VHA overall.

- Establish a transformation program management office with authority and funding (redirected from current central and local funding mechanisms) to implement the system-wide reworking of VHA. This will include establishing priorities, defining timelines for execution, allocating resources, and instituting appropriate metrics for success. It should merge relevant components of MyVA, the *Blueprint for Excellence*, and other ongoing initiatives into one coherent, focused transformational approach.

- Require evidence-based systems models to inform and implement integrated solutions that balance governance, operations, data and tools, and leadership.

It will be the charge of Congress, the Commission on Care, and VA leadership to see that these recommendations and resulting transformation efforts are given the necessary attention and support that they—and our nation's Veterans—deserve.

Table 1. Assessment Areas

	TOPIC	FOCUS	ORGANIZATION
A	Demographics	Current and projected demographics and unique health care needs of the patient population served by the Department.	RAND Corporation
B	Health Care Capabilities	Current and projected health care capabilities and resources of the Department, including hospital care, medical services, and other health care furnished by non-Department facilities under contract with the Department, to provide timely and accessible care to Veterans.	RAND Corporation
C	Care Authorities	The authorities and mechanisms under which the Secretary may furnish hospital care, medical services, and other health care at non-Department facilities, including whether the Secretary should have the authority to furnish such care and services at such facilities through the completion of episodes of care.	RAND Corporation
D	Access Standards	The appropriate system-wide access standard applicable to hospital care, medical services, and other health care furnished by and through the Department, including an identification of appropriate access standards for each individual specialty and post-care rehabilitation.	Institute of Medicine
E	Workflow – Scheduling	The workflow process at each medical facility of the Department for scheduling appointments for Veterans to receive hospital care, medical services, or other health care from the Department.	McKinsey & Company
F	Workflow – Clinical	The organization, workflow processes, and tools used by the Department to support clinical staffing, access to care, effective length-of-stay management and care transitions, positive patient experience, accurate documentation, and subsequent coding of inpatient services.	McKinsey & Company
G	Staffing/ Productivity	The staffing level at each medical facility of the Department and the productivity of each health care provider at such medical facility, compared with health care industry performance metrics.	Grant Thornton LLP
H	Health Information Technology	The information technology strategies of the Department with respect to furnishing and managing health care, including an identification of any weaknesses and opportunities with respect to the technology used by the Department.	The MITRE Corporation
I	Business Processes	Business processes of VHA, including processes relating to furnishing non-Department health care, insurance identification, third party revenue collection, and vendor reimbursement.	Grant Thornton LLP
J	Supplies	The purchasing, distribution, and use of pharmaceuticals, medical and surgical supplies, medical devices, and health care related services by the Department.	McKinsey & Company
K	Facilities	The process of the Department for carrying out construction and maintenance projects at medical facilities of the Department and the medical facility leasing program of the Department.	McKinsey & Company
L	Leadership	The competency of leadership with respect to culture, accountability, reform readiness, leadership development, physician alignment, employee engagement, succession planning, and performance management.	McKinsey & Company

1   Introduction

Requirements: Several congressional hearings in the spring and summer of 2014 attempted to explore the potential uneven access and quality in the Veterans Health Administration (VHA) health care system and to identify the sources of the problems that were dominating the press. In August 2014, Congress passed the Veterans Access, Choice, and Accountability Act of 2014 (Pub. L. No.113–146, 128 Stat. 1754), also known as the Veterans Choice Act. Section 201 of the Veterans Choice Act, Independent Assessment of the Health Care Delivery Systems and Management Processes of the Department of Veterans Affairs—hereafter called the Independent Assessment—calls for a private-sector entity or entities to "conduct an independent assessment of the hospital care, medical services, and other health care furnished in medical facilities of the Department."[10] The Act specifically directed that the assessments be conducted in 12 areas, covering a broad spectrum of VHA services, operations, and support. Eleven of these assessments were conducted under the auspices of the CMS Alliance to Modernize Healthcare (CAMH), a federally funded research and development center sponsored by the Centers for Medicare & Medicaid Services (CMS) and operated by The MITRE Corporation. MITRE entered into contracts with three organizations to help execute the required assessments, with the exception of Assessment D (Access Standards), which VHA separately contracted to the Institute of Medicine (IOM). Table 1 identifies the specific assessment areas and the organizations conducting the assessments.

Activities: For the 11 CAMH assessments, the assessment teams conducted numerous activities to better understand VHA processes, functions, and operations. As Table 2 illustrates, they captured and utilized a vast amount of information gathered through site visits, surveys, data requests, and focused interviews. All of the individual assessment reports, summarized in Appendices A through L and contained in Volume II, provide a comprehensive discussion of the analytical techniques that each team used to conduct its assessment. This Integrated Report was created by applying an integrated systems perspective across all of the individual assessments' activities, findings, and recommendations.

Table 2. Data Collection, Assessment, and Integration Activities

Conducted 87 site visits to 38 VAMCs, 16 primary care community-based outpatient clinics, 7 multi-specialty community-based outpatient clinics, 1 health care center, 13 VISN headquarters, 4 construction and facilities management offices, 2 acquisition centers, 2 consolidated mail outpatient pharmacies, 3 consolidated patient account centers, 1 health administration center, and 6 active major construction sites.
Conducted numerous interviews and workshops with VA and VHA leadership, staff, and union representatives.
Conducted extensive literature reviews that included 137 previous assessments of the Veterans health care system.

[10] United States. Congress. Veterans Access, Choice, Accountability, and Transparency Act, 38 U.S.C. § 1701 (2014) (Pub. L. No.113–146, 128 Stat. 1754).

Met with 27 leading private health care organizations and obtained information from 10 Veteran Service Organizations (VSOs). Visited four health care systems that have undergone successful major transformations in the last 10 years.
Conducted 5 individual-level surveys to include leaders at VA administrative parent organizations, schedulers, providers and administrators, inpatient clinical staff members at all VAMCs, and VHA employees about its leadership beliefs and practices.
Received 560 data sets from VHA; received and analyzed more than 20,000 files.
Created an independent Blue Ribbon Panel consisting of 16 preeminent health care industry leaders to leverage their expertise in health care industry best practices and innovative practices. The panel members (listed in Appendix Q) remained engaged throughout the assessment process and provided advice and feedback on the integrated assessment approach and this Integrated Report.

Limitations: These efforts had certain limitations:

- The assessment teams assumed that the quality, reliability, and accuracy of the data provided by VHA were acceptable. Sometimes data were unavailable, used non-standard definitions, or appeared to have inconsistencies. Conducting audits was beyond the scope of this effort.

- The assessments did not include a survey of Veterans' experiences or perceptions. The defined time frame did not permit the design and implementation of a formal survey. We engaged Veterans Services Organizations (VSOs) to gain their perspective on the viewpoints of their membership.

- The assessments did not compare costs of VA and non-VA care because the Veterans Choice Act did not require cost comparisons. The Congressional Budget Office (CBO) has previously reported to Congress on the challenges of comparing the costs of VA and non-VA care, citing the scarcity of cost-accounting data for Veterans' care and the complete absence of data on non-VA care received by Veterans who are also treated by VA.[11] We do recognize that the value of Veterans' health care, defined as health care outcomes relative to costs, should inform efforts for improvement.

- Due to time constraints, the assessment teams did not visit every Veterans Affairs Medical Center (VAMC). Rather, the assessment team implemented a process that defined an appropriate sample of medical facilities to visit and used data calls and surveys to cover the remaining facilities that could not be visited. The sample included representation across all (Veterans Integrated Service Networks (VISNs); satisfied assessment requirements; and 87 site visits, including visits to 38 VAMCs, were conducted. To ensure consistency across each site visit, we also ensured that the same

---

population (i.e., roles and units) were used for observation and focus-group participation.

Organization: The results of these efforts are captured in two volumes:

- Volume I contains this Integrated Report and one appendix for each assessment, summarizing that assessment's findings and recommendations.
- Volume II contains the detailed and complete assessment reports.

Table 3 provides the major elements of this Integrated Report:

- Sections 1–3 include the Introduction, Context, and Systems and are intended to enable readers to understand the purpose of the effort, to capture VHA's state at the time of the assessment, and to introduce the need for an integrated system-level perspective to resolve identified systemic findings.
- Sections 4–7 discuss the four interrelated systemic findings of concern and respective system-wide recommendations.
- Section 8 describes the transformational journey that VHA must embark upon to become a high-performing health care system.

This Integrated Report provides an integrating perspective based on the findings and recommendations from across the independent assessment reports. It does not provide a summary of the individual findings or recommendations of the assessments; rather, readers are strongly encouraged to study those assessments in detail.

The findings and recommendations from all of the independent assessment reports revealed four systemic findings, defined in Section 3, that are clearly interrelated and underlie many of VHA's recurring problems. This Integrated Report concludes that solving VHA's more challenging problems requires VA leadership to adopt systems thinking, a framework for solving problems based on the premise that a component part of an entity can best be understood in the context of its relationships with the other components of the entity, rather than in isolation. This approach takes into account the interdependencies of the parts to find the best combination of strategies that meet the needs of the whole. Systems thinking has been well established in many industries, including health care, and requires leaders to understand how components of the system should be working together, as opposed to how they are currently interacting. Systems thinking does not promote tackling individual problems independently because the solutions, more often than not, will be sub-optimal, non-scalable, and non-sustainable. This Integrated Report also concludes that VHA should establish a transformation program management office with authority and funding necessary to effectively implement a system-wide reworking of VHA based on systems thinking and that VHA should exploit evidence-based systems models to enable informed decisions about integrated solutions.

2 Context

The assessments focused on the care provided under the auspices of the U.S. Department of Veterans Affairs (VA). This care is primarily provided through the medical facilities operated by the Veterans Health Administration (VHA)—the VA organization directed by the Under Secretary for Health—and through health care funded by VA and provided outside of VHA facilities (i.e., purchased care or community care). Veterans also receive health care outside of VHA facilities that is not funded by VHA. Our focus excludes care that is not directly provided by or paid for by VHA.[12]

VHA is a multifaceted organization with several dynamics that impact how it operates. These include its mission, funding, size and scale, organizational construct, and an evolving patient population influenced by complex eligibility rules and multiple care options.

VHA Mission and Vision: VHA's stated mission is "Honor America's Veterans by providing exceptional health care that improves their health and well-being."[13] VHA aspires to the following vision:

> VHA will continue to be the benchmark of excellence and value in health care and benefits by providing exemplary services that are both patient-centered and evidence-based.

> This care will be delivered by engaged, collaborative teams in an integrated environment that supports learning, discovery and continuous improvement.

> It will emphasize prevention and population health and contribute to the Nation's well-being through education, research and service in national emergencies.[14]

Fiscal Resources: VHA estimates that its funding for fiscal year (FY) 2015 will total $59 billion, including $3 billion in third-party collections.[15] Currently, VHA's budget request is based on estimates developed two years prior and is constrained by overall federal budget growth. Thus, VHA may be limited in its ability to respond quickly to unexpected demand for health care, especially after changes in eligibility. This happened several times in the past: for example, after eligibility reform in 1996 and when certain diagnoses were designated presumptively service connected for Veterans who served in Vietnam, the Gulf War, and other situations.

Size and Scale: VHA has an extensive geographic presence across the United States and its territories and manages a significantly large number of facilities. It provides health care through 21 Veterans Integrated Service Networks (VISNs). In each VISN, hospitals known as VA Medical

---

[12] The terms VA and VHA are not interchangeable. Throughout this report, VA refers to the department and VHA refers to the administration within the department.

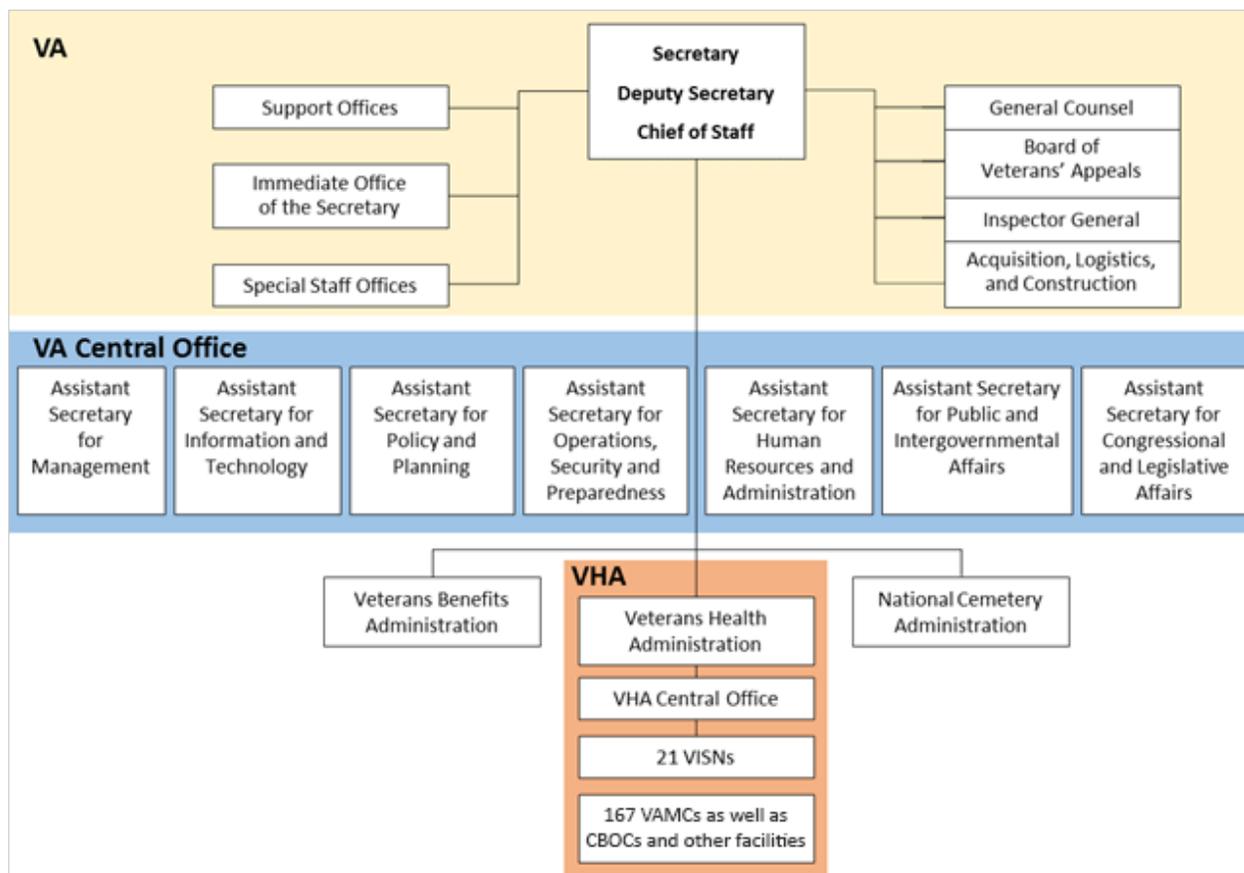
Centers (VAMCs) coordinate with smaller clinical sites known as community-based outpatient clinics (CBOCs) to care for Veterans in a specified geographic area. In addition to providing direct patient care to Veterans, VHA also provides medical education for physicians and other health care providers (it has been estimated that 70 percent of all U.S. physicians received some of their training from VHA),[16] and conducts critical clinical, basic, and health services research.

Figure 2. U.S. Department of Veterans Affairs Organization Chart


Organization: As Figure 2 indicates, Veterans Health Administration is one of three administrations under the Secretary of Veterans Affairs. It is by far the largest administration, with 89 percent of the full-time equivalent (FTE)[17] staff employed by VA and 87 percent of the fiscal year (FY) 2016 VA discretionary budget.

- All three administrations rely on the VA Central Office (VACO) to provide Information Technology (IT), Human Resources (HR), Contracting, Administration, Acquisition, Logistics, and Construction Services, among others.

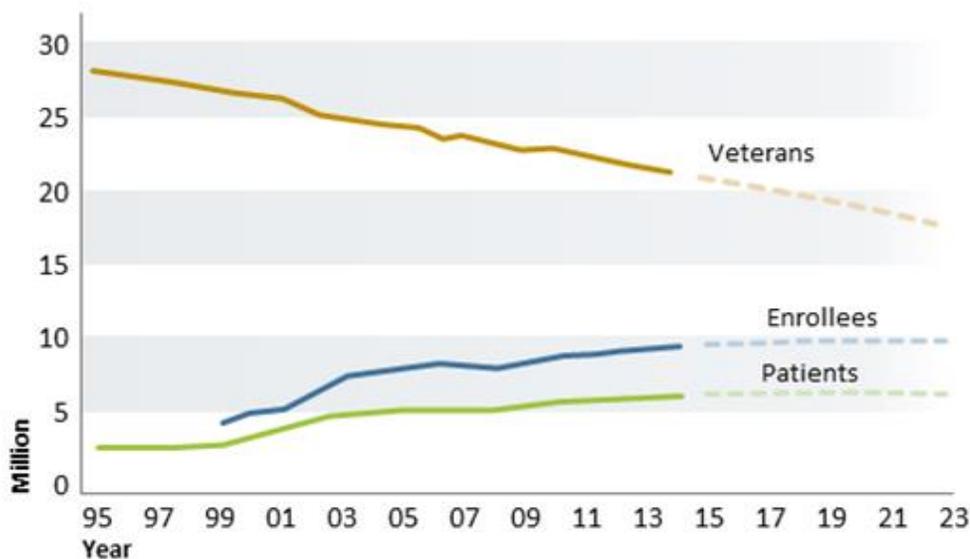
- VHA also has a Central Office (VHACO) that includes offices for Operations and Management, Policy and Services, Nursing Services, Academic Affiliations, Business, Medical Inspector and Quality, Safety, and Value.
- The 167 VA Medical Centers (VAMCs) are distributed across 21 Veterans Integrated Service Networks (VISNs). These VAMCs and VISNs are nested within VHA under the direction of VHACO. VHA and VHACO are, in turn, nested under VA and the VA Central Office.

Evolving Population of Veterans:[18] Figure 3 illustrates trends in the total Veteran population, enrollment, and use of VA care. In 2014, the Veteran population totaled 21.6 million who had served on active duty in the military; of these, 9.1 million were enrolled for VHA health care coverage. Among those enrolled, about 5.9 million Veterans used a VHA hospital or clinic at least once during the year. Historical data show that the number of Veterans peaked around 1980 at 30 million and has steadily declined since then, but the number of VHA health care enrollees and users has steadily increased over the 20 years for which data are available.

The Veteran population is projected to continue to decline over the next decade by an additional 19 percent to 17.5 million. The number of enrollees and patients is estimated to reach its peak level in 2019 before plateauing or possibly declining in future years, as the population decline begins to overtake the upward trend in use of VHA health care by eligible Veterans. Changes in access to VHA in-house or purchased care, enrollment eligibility, or external factors could result in a resumption of the upward trend or a more rapid decline.

Figure 3. Trends in the Veteran Population, Enrollment, and Use of VA Care


Source: Congressional Research Service, Assessment A Projections

---

[18] This information is presented in RAND Corporation Assessment A (Demographics) in Volume II.

In terms of geographic distribution, over the next decade, the Veteran population will become more concentrated in urban areas, and the relative share of the Veteran population in the Ohio River Valley region will diminish. However, migration is less frequent among Veterans than non-Veterans and will not play a substantial role in the geographic distribution of Veterans between 2014 and 2024. While migration rates vary with a range of demographic characteristics, the overall trend is one of slow decline in migration rates generally.

Health Conditions:[19] Veterans are substantially older and therefore face more chronic conditions than the general civilian population. Approximately 50 percent of all Veterans are age 65 or older, compared to only 17 percent of the civilian population. Veterans report more health problems than civilians. Compared to Veterans who do not use VHA health care, VHA patients are older, less socio-economically well off, and experience a higher prevalence of common chronic conditions (such as diabetes and cancer). The prevalence of these conditions is expected to increase over the next 10 years.

The overall prevalence of mental health conditions is 56 percent higher among VHA patients than other Veterans. Twenty-five percent of all patients seen at VHA have a mental health condition, and the prevalence of post-traumatic stress disorder (PTSD) among VHA patients (at four percent) is 11 to 14 times the prevalence among Veterans not using VHA care. When combined with the otherwise rare conditions related to combat—amputation, traumatic brain injury, blindness, and severe burns—VHA handles a patient mix that is distinct from what civilian community providers typically treat. VHA also faces challenges, as do civilian providers, in treating patients who are homeless or have unstable living arrangements. An estimated 50,000 Veterans were homeless in 2014, and while overall homelessness among Veterans is declining, some areas still serve a large homeless population.

Complex Eligibility Rules: The Veterans Health Care Eligibility Reform Act of 1996 established the foundation for today's eligibility rules for Veterans' health care. The Act defined eligibility priority groups while mandating care for Veterans with service-connected health conditions, service-connected disabilities, exposure-related health conditions, and those without other means to pay for their care. However, health care for these Veterans is not an entitlement because it is limited by "the amount provided in advance in appropriations Acts for such purposes."[20] It is worth noting that VHA has discretion in the law over how to provide care, but it is required to maintain specialized treatment and rehabilitation programs for spinal injuries, blindness, amputations, mental illness, and other serious service-connected health conditions.

The threshold for enrollment eligibility has changed several times since 1996. After Congress expanded health care eligibility to all Veterans, the number of enrollees increased rapidly. By 2003, VHA found itself "unable to provide all enrolled Veterans with appointments within a reasonable time."[21] To ensure quality and timeliness of care for higher priority Veterans, VHA

[21] Enrollment-Provision of Hospital and Outpatient Care to Veterans Subpriorities of Priority Categories 7 and 8 and Annual Enrollment Level Decision, 38 CFR 17 (2003)

terminated the enrollment of Veterans who do not have a compensable service-connected disability and do not have incomes below the threshold used to determine which Veterans cannot pay for their care. The income threshold was relaxed in 2009, opening enrollment to Veterans whose incomes are within 10 percent of the threshold. Finally, Veterans who deployed to a combat theater after November 2009 are automatically eligible to enroll for up to five years after leaving the military without having to first establish their priority group.

Multiple Sources of Health Coverage for Veterans: Health care planning for VHA must also consider the fact that most Veterans have at least one source of health insurance coverage other than VHA health care, and Veterans with other coverage have markedly different VHA use rates than Veterans without other sources of coverage. Slightly more than half of Veterans reporting to non-VA sources of coverage have used VA health care services in the past, and 43 percent report using VA health care services in the past six months. Only eight percent of Veterans using private coverage alone report using VA health care in the past six months.

Purchased Care:[22] Historically, VHA treated Veterans almost exclusively in its own facilities. In recent years, the use of purchased care has increased rapidly and now accounts for about 10 percent of expenditures. The Veterans Choice Act guaranteed purchased care for enrolled Veterans who, under certain parameters, are unable to access care in VHA facilities. VHA has begun to develop a more robust purchased-care program, relying on a network of community providers who have agreed to treat Veterans and provide information about the care provided.

Quality of Care:[23] Although Congress did not specify quality of care as a specific assessment area, one assessment did characterize current VA quality of care by including a review of previous studies and new analyses that compared VA's quality with non-VA providers on a published set of quality measures. After a careful examination of many published, peer-reviewed studies, Assessment B (Health Care Capabilities) concludes that VHA health care quality is better on many measures than non-VA providers' care, while similar or worse on other measures. In new analyses comparing VHA's quality with non-VA providers, VHA performed the same or significantly better on average than the non-VA provider organizations on 12 of 14 effectiveness measures (providing recommended care) in the inpatient setting, and worse on two measures. On average, VHA performed significantly better on 16 outpatient Healthcare Effectiveness Data and Information Set® (HEDIS) measures of effectiveness compared with commercial health maintenance organizations (HMOs); on the 15 outpatient HEDIS measures of effectiveness that were available for Medicaid HMOs; and on 14 of 16 outpatient effectiveness measures compared with Medicare HMOs. On 6 of 10 patient-centeredness measures, on average, patients in VA hospitals reported significantly less favorable experiences with the care they received than did patients in non-VA hospitals. Assessment B observed marked differences between highest and lowest performing VA facilities for most quality measures—indicative of the uneven quality of care suggested in Section 1.

---

[22] This information is presented in RAND Corporation Assessment C (Care Authorities) in Volume II.

[23] This information is presented in RAND Corporation Assessment B (Health Care Capabilities) in Volume II.

Shift from Inpatient to Outpatient Care: U.S. health care has been transforming from hospital-centric sick care to an outpatient model that emphasizes primary and preventive care. Data from the American Hospital Association reveals a decline in inpatient admissions since 2008, dropping from 35.8 million community hospital admissions to 34.4 million. Outpatient visits over the same period grew from 624 million visits in 2008 to 675 million visits in 2012 (Figure 4[24]). These trends are traced to health care reform changes and the adoption of new models of care that accommodate more patients in an outpatient setting. More hospitals are establishing medical home programs. "In 2013, 20.4% of hospitals had a medical home program compared with 14.5% in 2011."[25] A review of Medicare data from 2004 to 2011 reveals that inpatient admissions per Fee for Service (FFS) beneficiary declined by 7.8 percent while the number of outpatient services per FFS beneficiary increased by 33.6 percent across all types of insurance.[26] Within VHA, outpatient visits are increasing while inpatient Bed Days of Care has declined, with some VISNs experiencing more dramatic swings than others. These trends will eventually impact the number, size, and configuration of the health care facilities required to provide support to Veterans.

3 Systems

Systems Thinking: A review of the findings included in the assessment reports indicates that each finding has an impact on patient care, and many findings have been recognized by previous studies.[27] Over the last 10 years, more than 15 studies and assessments have addressed scheduling issues alone. Prioritizing these findings and then solving them individually is tempting, but such an approach would not guarantee a sustainable solution. While focusing on one simple metric and attacking that measure is tempting, doing so may be transient and may fail to address the underlying problems. As H.L. Mencken stated, "For every complex problem, there is an answer that is clear, simple, and wrong." Often, the simple answer is not sustainable, is not scalable, and can even create unintended consequences.

An analysis of the Veterans' access issue illustrates this conclusion. Using wait times as the one metric for patient access, Assessment D (Access Standards) reports an average wait time of 43 days for new primary care appointments, with a range of 2–122 days across all VA facilities, based on an October 2014 VHA report. Comparison data from a review of Massachusetts physicians in the civilian sector showed average wait times of 50 days for internal medicine and 39 days for family medicine appointments. This suggests that, on average, VHA was not that different from the civilian sector. Assessment B (Health Care Capabilities) also "did not find evidence of a system-wide crisis in access to VA care." But looking only at overall averages can mask troubling instances of poor access and can preclude the investigation of the underlying causes of those instances. Assessment D asserts that achieving sustainable access improvements requires a systems approach, incorporating multiple factors: systems strategies, supply and demand alignment, reframing the type of patient encounter, the need for standards, the need for evidence-based best practices, and leadership. Each of these will require its own evidence-based metrics and benchmarks. Taken together, they will provide a much more comprehensive and accurate assessment of access. Creating a locally tailored model of these pieces gives VHA the ability to understand how access varies from location to location. Local models can then be aggregated to provide understanding of overall system performance while still retaining local granularity to uncover previously hidden issues.

VHA must adopt a systems perspective to address its most challenging problems, including access. Systems thinking views problems within the context of the overall system and avoids isolated solutions to specific problems. It takes into account the interdependencies of the parts to find the best combination of strategies that meet the need of the whole.[28] This approach has

---

[27] This team reviewed 137 previous assessments of VHA, including reports by the Government Accountability Office, Veterans Administration Office of the Inspector General, and multiple other organizations. These assessments were conducted between 1998 and 2015. (Seventy-seven percent of the reports were conducted in the last five years.) They contain 790 findings about the state of VHA health care, many of which are overlapping. About 80 percent of the findings identified in this Integrated Report are aligned with or reflect those previous findings. The unique value of this report is not in the list of findings but in the recognition of the need for an integrated systems approach to address the underlying causes of those findings.

[28] Frank, M. (2000, March 31). Engineering systems thinking and systems thinking. *Systems Engineering, 3(3),* 163–168.

been well established in many industries, including health care. This approach often enables leaders to exploit identified strengths and to reframe problems into opportunities based on an appreciation of how components of the program should be working together, as opposed to how they are currently interacting. As was stated in a recent Senate hearing on VHA, the tendency to chase "shiny objects"[29] must be avoided and replaced by focusing on an integrated process executed at the enterprise level. The Government Accountability Office (GAO) has also encouraged VA to address those systemic findings that will enhance the ability of VHA to provide high-quality health care to Veterans.[30]

Systemic Findings: To understand the interdependence of issues and the potential causes of systemic problems in VHA, multiple reviews of all the findings across the assessment reports were conducted. Through an analysis of industry benchmarks and best practices, insights from health care executives and high-performing health care organizations, the perspective of our Blue Ribbon Panel, and interactions with Veterans Service Organizations, four systemic findings repeatedly emerged. Each of these systemic findings then motivates a cornerstone recommendation that should be integrated into a VHA systems approach.

Finding 1—A disconnect in the alignment of demand, resources, and authorities

VHA's mission is inspirational and widely accepted by employees, but there are significant geographic variations with respect to how the mission is translated into action for individual Veterans. Complex eligibility rules make determining which Veterans are covered and what services they receive a challenge, and navigating VHA is often difficult for Veterans—a problem exacerbated by incomplete guidance and non-standardized business processes. Furthermore, the growing role of outside providers has not been integrated effectively into VHA's operating model, which is based on providing direct care within VHA facilities.

At present, VHA is over-committed in some geographic areas, given its broad mission, an expanding list of automatic eligibility criteria, and limited resources. Matching supply and demand at the local level is challenging because supply is relatively fixed each year once service projection models allocate resources to each facility through the appropriation and budgeting process.

Recommendation 1—GOVERNANCE: Align demand, resources, and authorities.

Finding 2—Uneven bureaucratic operations and processes

Several centralized operational and support functions appear to have lost customer focus and do not adequately support the needs of the medical centers. Individual VAMCs have adopted

---

local implementations of certain processes, but many of these were found to be unnecessarily complex and, not surprisingly, inconsistent across VHA. In many cases, these centralized and local process issues have become inefficient and bureaucratic, creating a direct negative impact on the overall Veteran experience and timely access to care.

These widely varying processes highlight VHA's complexity. Severe problems may manifest themselves at one facility, while another constantly receives tributes from Veterans and health care experts. The oft-quoted reminder, "if you've seen one VA hospital, you've seen ONE VA hospital," captures this reality.

Recommendation 2—OPERATIONS: Develop a patient-centered operations model that balances local autonomy with appropriate standardization and employs best practices for high-quality health care.

Finding 3—Non-integrated variations in clinical and business data and tools

A lack of common, integrated VHA enterprise systems and tools negatively impact VHA's operations and resulting data. Inconsistent and ineffective data collection and analysis undermines rapid, evidence-based assessment and improvement of quality and customer satisfaction. VHA lacks a holistic, enterprise approach to collecting and leveraging its data. Data interchange with the Department of Defense (DoD) and external health care providers is limited, which creates unnecessary clinical risk. Since newly discharged Veterans often become VA patients, interoperability with DoD is necessary and expected. These shortfalls hinder using available data to support effective decision making and performance management.

Recommendation 3—DATA AND TOOLS: Develop and deploy a standardized and common set of data and tools for transparency, learning, and evidence-based decisions.

Finding 4—Leaders are not fully empowered due to lack of clear authority, priorities, and roles

VHA leaders operate within a challenging and disempowering environment that discourages emerging leaders from seeking promotion within VHA. Key leadership positions remain vacant or are staffed with acting leaders, and more than half of executives are eligible for retirement, potentially creating a larger number of vacant positions. A misalignment of accountability and authority exists within a broader VHA culture that is characterized by risk aversion and lack of trust. Those leaders who are effective too often achieve positive outcomes despite the challenges of the organization within which they operate.

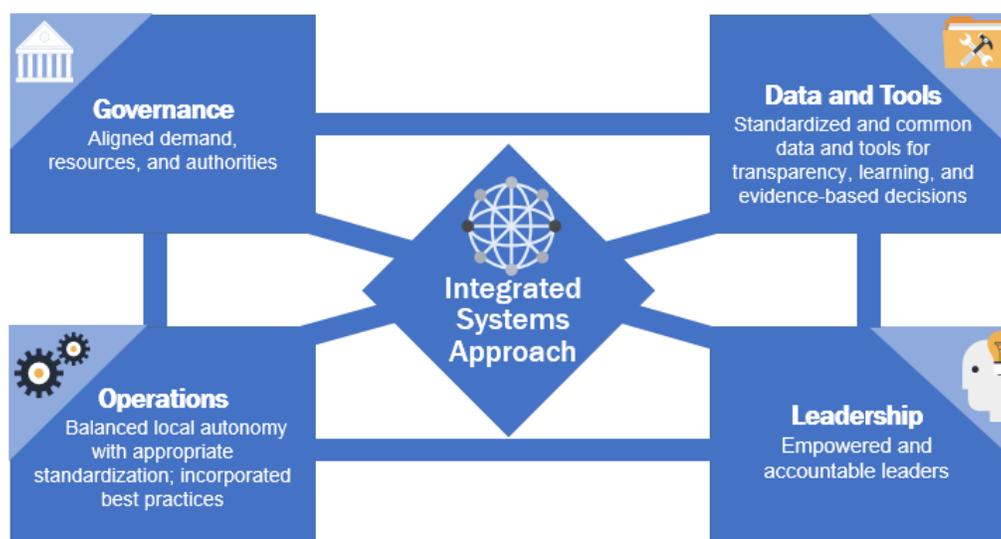
Recommendation 4—LEADERSHIP: Stabilize, grow, and empower leaders; galvanize them around clear priorities; and build a healthy culture of collaboration, ownership, and accountability.[31]

Integrated Systems Cornerstones: These four systemic findings in governance, operations, data and tools, and leadership all contribute to the critical problems that plague VHA. It should not

---

[31] This information comes from McKinsey & Company Assessment L (Leadership) in Volume II.

be surprising, then, that when addressing any one problem, the solution must integrate all of these systems cornerstones as part of a sustained solution. For example, improving access in a scalable and sustainable manner is more than just authorizing and funding temporary overtime to create more appointments; improving access must also include forecasting demand, streamlining scheduling processes, improving the efficiencies of existing hospital capacities, changing the way health delivery occurs to include telehealth, and having clarity and authority for using purchased care options. Similarly, even funding $10 billion for Choice Cards without addressing the other parts of the system such as educating Veterans about their new options and changing the culture to embrace non-VHA providers can lead to poor results. Figure 5 illustrates the four integrated systems cornerstones that must be addressed together to enable enduring solutions in VHA.

Figure 5. Integrated Systems Cornerstones


Applications of the Integrated Systems Approach: Three examples emerge that demonstrate the value of the systems approach in addressing the significant challenges facing VA. These examples deal with facilities management, Veteran patient access, and health information technology.

Facilities[32]: Consider the challenges that VA must resolve in managing its capital program in facilities management. Provided that average funding levels remain consistent over the next 10 years, the $51 billion capital requirement would significantly exceed the anticipated funding level of $16–26 billion.[33] Not only would this shortfall jeopardize the capital program, it would also threaten the financial integrity of the entire VHA health care delivery system and, in turn, significantly impact the quality of health care provided to Veterans. Viewing this primarily as a funding problem would be shortsighted. Rather, interdependent findings exist in each of the

---

[32] This information comes from McKinsey & Company Assessment K (Facilities) in Volume II.

[33] This information comes from McKinsey & Company Assessment K (Facilities) in Volume II.

---

four cornerstones that need to be addressed in an integrated fashion to achieve a sustainable solution, as shown in Table 4.

Table 4. Facilities Challenges Through the Lens of the Systems Approach

Governance
External and internal constraints limit VHA's ability to deliver and operate medical facilities at the level of private-sector benchmarks; to appropriately rebalance inpatient and outpatient facilities; and to accommodate future trends, including telehealth.
Investments in facilities are not effectively linked to workload growth; existing space is not being used at its highest efficiency; eliminating underutilized space is difficult.
Expected funding levels do not support identified capital needs.
Operations
Lengthy approval and funding timelines hinder VHA's ability to meet the identified space requirements to keep up with Veteran demand and invest in facilities updates that align with changing models of care.
VHA has no integrated system to manage the entire leasing process timelines, comprehensive tracking, or measurement of the impact of the leasing program.
A large majority of facilities noted challenges in hiring staff and filling vacant positions that were open and for which budget had been allocated.
Scope and design criteria for major projects are frequently subjected to major changes, especially during the design phase, affecting overall cost and schedule.
Data and Tools
Data capture occurs at multiple levels and through multiple tools, generating multiple sources of truth about the status of the capital program.
Tools for developing Strategic Capital Investment Plan business cases rely on individual effort versus a systematic process to consider creative alternatives to capital solutions.
Systems do not consistently capture key performance indicators. The metrics are not standardized across all stakeholders.
Leadership
There are recognized shortfalls in overall accountability, role clarity, personal ownership, internal communication, and proactive problem-solving approaches that limit VA's and VHA's ability to deliver the correct projects on time and on budget.
The broader culture of facilities functions is characterized by silos, risk aversion, and role ambiguity, resulting in an inability to consistently advance projects in an efficient manner.
Competition for limited funds has led leaders to make a range of choices in developing projects that favor approval strategies over efficient project delivery.

Viewing these facilities challenges through the lens of the integrated systems approach reveals the complexity of the problem; the integrated nature of the required transformation; and the

opportunity to reframe the facilities challenges as part of a larger set of interdependent pieces of VHA's overall health care system. Facility challenges can be significantly mitigated by a transformative realignment throughout the capital program deploying best practices in leasing and contracting; realigning the strategy of the capital program to improve project selection, optimize the infrastructure portfolio, implement innovative care delivery models, understand demand-based needs, and explore and partner with purchased-care opportunities; and reevaluating funding requirements. Closing or resizing facilities to match local demand and resizing to take into account inpatient and telehealth trends will avoid significant costs. Understanding local demand can lead to a smaller facility need with overflow arrangements with local private-sector options. Other key opportunities include improving contracting and leasing processes as well as considering when to outsource construction. In short, employing the systems view could help reframe the vision for future health delivery and significantly reduce VHA's current and future capital investment issues. It also enables VHA to avoid being burdened in the long term with hospital overcapacity as the nature of health care delivery trends toward smaller inpatient facilities, increasing outpatient care, and more virtualized health care delivery.

Access: As introduced earlier in Section 3, current VHA access challenges can be viewed through a systems perspective, as shown in Table 5. Multiple findings contribute to the access problem, and they are distributed among all four cornerstones, with clear interdependencies. Taken together, they provide a much more comprehensive understanding of the access problem, and demonstrate why point solutions will fail. Initial efforts to shorten wait times focused on a long-standing shortage of physicians.[34] However, this addresses only one issue in an integrated set of issues. A sustainable solution depends on a systems approach to the access challenge.

Table 5. Access Challenges Through the Lens of the Systems Approach[35]

Governance
Congress stipulates appointment wait times as the access metric
Lack of governance commitment on basic access principles
Lack of governance to ensure system-wide standards are developed, proposed, tested and appropriately applied based on local conditions
Operations
Lack of identification and use of evidence-based best practices
Approaches do not balance supply and demand, limited ability to modulate capacity, or implement surge contingencies to include technology-based alternatives to in-person visits

---

[34] Voorhees, J. (2014, November 12). Less firing, more hiring. Slate.com. Retrieved from http://www.slate.com/articles/news_and_politics/politics/2014/11/veterans_affairs_overhaul_the_va_should_ worry_less_about_cleaning_house.html

[35] This information comes from the Institute of Medicine Assessment D (Access Standards) and McKinsey & Company Assessment E (Workflow – Scheduling) in Volume II.

Substandard processes in patient scheduling; lack of centralized call centers
Data and Tools
Lack of patient access metrics, including data on patient and family experience, scheduling practices, patterns and wait times, cycle times, and effective care continuity
Lack of real-time capacity data
Definition of a patient encounter precludes exploiting alternative engagement approaches, including non-physician clinicians and technology mediated consultations
Leadership
Lack of employment of and commitment to systems approach
Lack of accountability that would ensure delays in access are addressed by all relevant stakeholders across care continuum, rather than with piecemeal, independent process changes
Lack of facility leadership focused on continuous assessment and adjustment at each care site

Health IT: As another example of the value of the systems approach, Assessment H (Health Information Technology) discovered that few major improvements have been implemented to the primary health care software system (VistA) in the past 10 years. Many problems undermine deployment of new capabilities. Viewed through the lens of a system approach in Table 6, issues with governance, operations, data and tools, and leadership all contribute to the inability of VA to successfully implement and modernize VistA.

Table 6. Health IT Challenges Through the Lens of the Systems Approach

Governance
Inadequate collaboration between VA's centralized IT organization and VHA results in failure to prioritize IT capabilities that will support VHA health care needs
Lack of a robust, detailed strategy and roadmap for scheduling initiatives across VA to integrate Veteran scheduling via all modalities
Lack of dedicated VHA IT executives
Operations
Document-centric, schedule-focused project management and execution processes that preclude delivery of needed capabilities
Challenges in building and maintaining a skilled health informatics workforce
Lack of technical support to Veterans for home telehealth

Data and Tools
Lack of standard clinical documentation impedes clinical research and electronic health record exchange with DoD and private sector health care providers
Inconsistent and ineffective data collection within and across VA medical facilities prevents evidence-based assessment and improvement of quality and customer satisfaction
Overly complex processes for system development impede cost-effective delivery of new health IT capabilities and limit VA's ability to measure the value of IT investments

Leadership
Internal project-focused central IT service management philosophy vice customer focused
Turnover in the VA CIO position (four in the last 10 years) has precluded an enduring focus on a coherent approach to consolidate new infrastructure technologies, resulting in even greater software complexity
Lack of organization and staffing in the VistA Evolution program preclude successful management, development, and integration of a large complex software program

Continuous Improvement: The richness of the systems approach extends not just to facilities, access, and IT, but across many of VHA's biggest challenges. While complex problems benefit greatly by reframing problems in creative ways, systems solutions also work well for improving existing processes and motivating people to believe they can successfully change. Continuous improvement is one such approach that often uses a Plan-Do-Study-Act cycle[36] that identifies, reduces, and eliminates suboptimal processes for continuous incremental or breakthrough improvements. This relies heavily on measuring, analyzing, and experimenting for successful innovations. VHA's current culture would benefit greatly from instituting continuous improvement more aggressively so that everyone participates, can see progress, and can build on the pride they have in being part of VHA. Some of VHA's best performers already focus on continuous improvement, but it is not widely adopted as a standard way of operating. Transforming any organization, especially one the size of VHA, requires that everyone understands, feels accountable for, and acts daily on how to continuously improve the organization. It is as much about engaging the people as it is about fixing the processes.

In summary, Table 7 shows each systemic finding, the associated recommendations to address each finding, and a short list of early actions to turn each weakness into a strength.

[36] Taylor, M.J., et al. (2013, August 12). Systematic Review of the Application of the Plan-Do-Study-Act Method to Improve Quality in Healthcare. BMJ Qual Saf 0:1-9. doi:10.1136/bmjqs-2013-001862

Table 7. Systemic Findings and Recommendations

Finding 1: A disconnect in the alignment of demand, resources, and authorities
Recommendation 1—GOVERNANCE: Align demand, resources, and authorities
Establish a governance board to develop fundamental policy, define the strategic direction, insulate VHA leadership from direct political intervention, and ensure accountability for the achievement of established performance measures.
Require a patient-centered demand model that forecasts resources needed by geographic location to improve access and to make informed resourcing decisions.
Clarify and simplify the rules for purchased care to provide the best value for patients.
Finding 2: Uneven bureaucratic operations and processes
Recommendation 2—OPERATIONS: Develop a patient-centered operations model that balances local autonomy with appropriate standardization and employs best practices for high-quality health care
Right size and reorient the VHA Central Office to focus on support to the field in its delivery of care to Veterans.
Fix substandard processes that impede the quality of care provided to the Veteran.
Design and implement a systematic approach to identify best practices and disseminate them appropriately across the enterprise.
Finding 3: Non-integrated variations in clinical and business data and tools
Recommendation 3—DATA and TOOLS: Develop and deploy a standardized and common set of data and tools for transparency, learning, and evidence-based decisions
Use standardized clinical and administrative data for accuracy and interoperability.
Implement a single, integrated set of system-wide tools centered on a common electronic health record (EHR) that is interoperable across VHA and with DoD and community provider systems.
Transparently share performance metrics for leadership, clinical, and business functions across VHA to identify and adopt best practices for continuous improvement.
Finding 4: Leaders are not fully empowered due to a lack of clear authority, priorities, and goals
Recommendation 4—LEADERSHIP: Stabilize, grow, and empower leaders; galvanize them around clear priorities; and build a healthy culture of collaboration, ownership, and accountability
Push decision rights, authorities, and responsibilities to the lowest appropriate level throughout the organization.
Build on Veteran-centered behaviors to drive a culture of service excellence, trust, continuous improvement, and healthy accountability.
Revitalize the leadership pipeline through establishment of enterprise-wide, comprehensive succession management and leadership development functions.
Strengthen the appeal of senior leadership positions by pursuing flexibilities in hiring and compensation.
Establish sustained leadership continuity by extending tenure for key positions.

4   Governance

Finding 1: A disconnect in the alignment of demand, resources, and authorities
Recommendation 1—GOVERNANCE: Align demand, resources, and authorities
Establish a governance board to develop fundamental policy, define the strategic direction, insulate VHA leadership from direct political intervention, and ensure accountability for the achievement of established performance measures.
Require a patient-centered demand model that forecasts resources needed by geographic location to improve access and to make informed resourcing decisions.
Clarify and simplify the rules for purchased care to provide the best value for patients.

CURRENT STATE

VHA's primary function is clearly defined in Title 38 of the U.S. Code—to "provide a complete medical and hospital service for the medical care and treatment of Veterans."[37] To implement that function, VHA has defined its mission as "Honor America's Veterans by providing exceptional health care that improves their health and well-being."[38]

While this mission inspires and motivates VHA staff, it also creates a dilemma for those same individuals who are committed to its successful execution. It holds out the promise of unconstrained health care to all Veterans when, in reality, the capacity of VHA to meet that promise is constrained by the appropriated funding. While the mission captures the intent of comprehensive health care for all Veterans, VHA's authorities, resources, and flexibility are less comprehensive. This dilemma was fueled in part by congressional actions, including the Veterans' Health Care Eligibility Reform Act of 1996. This act mandates that VHA provides a broadly defined set of services for groups of prioritized Veteran populations, based on their eligibility, but "only to the extent and in the amount provided in advance in appropriations acts for such purposes."[39]

This prioritization approach was intended to provide VHA leadership with the flexibility to match the extent of care to annual budgets, and it has done just that. It has created a situation under which the organization manages to the budget, regardless of the level of demand envisioned by the aspirational mission statement. In addition, Congress appropriates VA's budget as a nondefense discretionary program; thus, congressional priorities can influence both the level of money available and the way VA can spend the money once allocated. Funding for other large federal health programs differs in important ways. Medicare is considered an

The views, opinions, and/or findings contained in this report are those of The MITRE Corporation and should not be construed as an official government position, policy, or decision.

entitlement program; funding is provided from the Medicare Trust Fund, spending is mandatory, and the program's annual cost has no formal budget constraint. TRICARE funding is included in the U.S. Department of Defense (DoD) appropriation and is therefore discretionary, but the benefit is well defined, and DoD must cover any costs incurred beyond the appropriated funding. For VHA, congressional priorities can also direct money away from the overall budget for patient care toward specific programs through the special purpose funds. According to interviewees at VA medical facilities, these silos of money can make it difficult for facilities to efficiently and effectively use their entire budgets in any given year.[40] When demand exceeds capacity to deliver care within the budget, the inevitable result is a decrease in access to care and unmet demand for some Veterans. As this report is written, VHA is facing a potential crisis in its ability to provide care as the demand for Hepatitis C therapy grows.[41]

> "It appears that the culture of leadership, management, and accountability is focused on making the funding fit at every level. Leadership at every level must have the confidence that if they have a need, they can ask for that need to be addressed. VA, the Administration, and Congress must resolve to make the true need the priority, not the need to make budget lines fit."
>
> *Deputy Director*
> *Veterans of Foreign Wars*
> *Before the U.S. Senate*
> *May 15, 2014*

This approach for funding VA complicates the development of a coherent strategic direction and has hindered a consistent interpretation of the mission across the enterprise. Local organizations interpret their expectations locally, leading at least one VAMC to promise excellent care to "every Veteran, every time!"[42] In an interview, one VAMC leader described the challenge in terms of "double messaging" around "managing to a budget" and "managing to the need." At present, VHA is over-committed in some geographic areas. Matching supply and demand at the local level is challenging because supply is relatively fixed each year once service projection models allocate resources to each facility through the appropriation and budgeting process.

Although the population of Veterans is expected to decline by 19 percent over the next decade, the demand for health care services is expected to rise before it levels off in five years, based on demographic factors (primarily aging)—and likely will rise even more if access to VHA health care is improved (Assessment B [Health Care Capabilities]). On the other hand, despite this possible growth in demand, in some areas and for some health conditions, VHA may not have a sufficient population of patients to sustain highly specialized service lines with enough volume to achieve and maintain clinical excellence.

---

[40] This information is presented in RAND Corporation Assessment B (Health Care Capabilities) in Volume II.

[41] Wagner, D. (2015, June 21). VA to outsource care for 180,000 vets with hepatitis C. *USA Today*. Retrieved from http://www.usatoday.com/story/news/nation/2015/06/21/va-outsource-care-vets-hepatitis/29059755/

[42] U.S. Department of Veterans Affairs. (2015). About the Huntington VA Medical Center. Retrieved from http://www.huntington.va.gov/about/index.asp

Congress and VA leadership must address this challenge. They must work to align VHA's promise to provide comprehensive health care to Veterans with VHA's capacity by defining the expected benefit—that is, the Veteran population to be served and the health care those Veterans will be provided. This will drive the allocation of the funding adequate to meet this demand. VHA must broadly and transparently communicate the strategy for delivering that care to Veterans, VHA employees, other stakeholders, and the public. To start, the following policy questions must be addressed:

- Who will VHA serve? Is it truly all Veterans, or a subset of Veterans whose care is mandated?

- What health care services will VHA provide, and in what settings? Will it provide all care necessary to advance population health and desired outcomes for individual Veterans? How will it address the various social needs (e.g., caring for the homeless) that can complicate the provisioning of services for some Veterans?

- How will VHA provide care? How will VHA determine the appropriate balance between provided care and purchased care? How should this care be customized at the local level to reflect local issues?

The implications of developing answers to these policy questions are significant. All eligible Veterans have not enrolled for health care. The Veteran population is aging and developing conditions and ailments that are not necessarily service related. At the same time, the health care landscape is evolving, changing the manner in which health care is being provided. To address these policy questions and to leverage the answers to those questions, three recommendations are provided.

RECOMMENDATIONS

- Establish a governance board to develop fundamental policy, define the strategic direction, insulate VHA leadership from direct political intervention, and ensure accountability for the achievement of established performance measures.

- Require a patient-centered demand model that forecasts resources needed by geographic location to improve access and to make informed resourcing decisions.

- Clarify and simplify the rules for purchased care to provide the best value for patients.

Establish a governance board to develop fundamental policy, define the strategic direction, insulate VHA leadership from direct political intervention, and ensure accountability for the achievement of established performance measures.

The fundamental policy questions about who is eligible for benefits and for which benefits are truly difficult ones that may engender heated debate and emotional responses. But these issues only represent current critical problems; moving forward, other contentious issues will need to be addressed. For example, attempts to realign resources or close facilities have been met with vehement demands that the "public input needs to carry weight with any changes in the

system."[43] Initiatives to close or eliminate older, often historic, VHA facilities can meet strong resistance from multiple groups. For example, some Veteran Service Organizations have objected to facility closures by suggesting that such closures would reduce the level of care to Veterans.

In the near term, several models could be tailored to address these policy issues in an objective and unbiased manner. Congress could charter a commission modeled after the 1955 U.S. President's Commission on Veterans' Pensions. This Commission studied different benefit packages that had been granted to Veterans, collected extensive information from various government agencies, and also surveyed randomly selected Veterans to develop statistical analyses of the use and effectiveness of various benefit programs. The studies compiled by the Commission were submitted to Congress and influenced subsequent legislative actions. A second model is the Defense Base Realignment and Closure (BRAC) Commission. That Commission was empowered to perform an independent analysis and evaluation of the Defense Department-proposed base closure list and present a report of its findings and its own suggestions to the President and to the American public. Once Congress received the presidentially endorsed report, it had a definitive suspense date to enact a joint resolution rejecting the report in full or the report became law. VA has already introduced this notion "in congressional hearings and has gotten very little pushback from authorizers and appropriators for a BRAC of its own."[44]

But these are short-term models that may not be able to provide the long-term oversight, guidance, and direction that is expected. VHA operates in a complex and dynamic environment, answering to a large number of stakeholders, sometimes with competing demands. It is a health care system managed as a government agency; some have suggested that Congress is VHA's "board of directors."[45] The long-term governance structure of a health care system can influence many aspects of that organization, to include capital investments, operations, staffing, and the definition and implementation of the strategic plan. Alternative governance models do exist. One was introduced by the Commission on the Future for America's Veterans, which proposed that Congress "establish a new entity with characteristics not unlike a federal government 'not for profit' corporation" that would be empowered with "unencumbered" authority to use all the assets of VHA to "maximize benefits to Veterans."[46] A second model, titled the "Independent Non-Taxing Unit of Government," suggests a governance structure

---

under which a health care board and administrative leadership "still have accountability to elected officials" but are "much more insulated" from direct political interaction.[47] The New York City Health and Hospitals Corporation (HHC), the largest municipal hospital and health care system in the United States, operates under such a model, as do other municipal and state health care systems. HHC underwent a series of transformative efforts and links the success of those efforts to "a series of successful service and clinical improvements…while also emphasizing continuity of leadership, system wide strategic planning, and board-level accountability for achieving performance objectives."[48]

Congress and VA should charter the Commission on Care to explore and identify the governance model that would best enable VHA to complete the proposed transformative efforts and sustain its ability to provide the highest quality health care to Veterans. The model that is developed should clearly focus on governance. VA currently has 25 advisory committees, some of which are mandated by Congress, to assess specific VA policies or programs. But these committees are, by title, focused on advising, not governing, and should not be considered a solution to this recommendation. Congressional endorsement is perhaps the key enabler to effectively implementing a governance board.

VHA should charter a transformation program office that has the authority and resources to implement a system-wide reworking of VHA. This office should be provided sufficient and dedicated funding to enable the envisioned transformation's execution without having to tax other offices or borrow from other initiatives. The office should act as the "guiding team,"[49] staffed by individuals with the right emotional commitment and core competencies in executing organizational change. The office should coordinate directly with the established governance body and should focus on establishing transformation priorities, defining timelines for execution, implementing both strategic and tactical initiatives, allocating resources, and instituting appropriate metrics and processes to measure progress and success. It should replace any ongoing change initiatives and merge the relevant components of MyVA, the *Blueprint for Excellence*, and other initiatives into one coherent, focused transformational approach.

Require a patient-centered demand model that forecasts resources needed by geographic location to improve access and to make informed resourcing decisions.

Assessment D (Access Standards) states that improvements in health care access will be underpinned by continuous assessment, monitoring, and realigning of supply and demand. The assessment also states that most clinical settings do not take a sufficiently broad view of the

various options to either increase supply or reduce demand, nor do they maintain the analytic capacity to observe, measure, and understand the dynamics involved. Without this information, patterns of variability will be unobserved, alternatives will go untapped, and a supply-demand mismatch—which is often unnecessary—will be inevitable and chronic.[50]

VA data and analytical systems face these challenges. In addition to the need for fundamental policy guidance, VA data systems and U.S. data collection efforts have limitations that hinder planners' ability to assess how demand for VA services might change over time. For example, there has not been a full accounting of the U.S. Veteran population since the 2000 Census. Current VA data collection systems do not assess detailed information on Veterans' health care conditions and health care utilization patterns. Data are often completely unavailable for Veterans who are not currently eligible or enrolled in VHA health programs. Additional data collection would be needed to fully understand Veterans' total health care needs, including use of care currently covered by private insurance or Medicaid.

Assessment A (Demographics) also suggests the importance of developing methods and models that respond with speed and agility to policy changes. Two existing VA models—the Enrollee Health Care Projection model and the Veteran Health Care Scenario Model—can be used to estimate, for instance, how changes in demographic characteristics or economic conditions may affect demand for VA services and related costs. Expanding these models to address changes in the civilian health sector, unanticipated changes in perceptions about health care quality, and groundbreaking new technologies will enable VA to address the types of uncertainties that current models may not address.[51]

Other assessments identify additional demand modeling requirements that would enhance health care provided to Veterans. These requirements would address challenges in facility planning and supply-chain management. These models could answer the need for an enterprise-wide, timely, population-based ambulatory appointment demand modeling capability to forecast appointment demand. They also could provide the basis for staffing models that justify the number of resources needed to meet patient access standards and to proactively identify and forecast staffing needs.

VHA should expand its utilization of dynamic simulation modeling. The fundamental premise of the application for dynamic simulation modeling in health care is that "health care delivery systems are inherently complex, consisting of multiple tiers of interdependent subsystems and processes that are adaptive to changes in the environment and behave in a nonlinear fashion."[52] Traditional analytical methods might neglect the wider health system impacts that can be critical for achieving desired health system goals. VHA leadership could underestimate or ignore the interactions among the leadership, governance, operations, and data and tools. The literature is beginning to highlight the increasing application of dynamic simulation

---

modeling methods to health care delivery systems. These tools enable the decision maker to better understand the dynamics and complexities of the system under analysis and the consequences, both intended and unintended, of recommended changes.

In summary, VHA should use predictive tools and dynamic simulation modeling to continually forecast local demand and underpin decisions addressing resource allocation. These patient-centered demand models should enable the management of resources to meet national, regional, and local variations in patient-centered demand.

Two examples of dynamic simulation modeling methods applied to health care delivery:

1) "The Mayo Clinic's Center for the Science of Health Care Delivery applied health care delivery systems thinking to predict the minimum number of beds needed to meet quality standards of care. The model incorporated assumptions about surgery growth and new patient recovery protocols, as well as smoothing surgery schedules and transferring long-stay patients from the ICU. The model predicted 30% lower bed supply requirements than did the traditional bed planning approach. System dynamics modeling was used for high-level planning of primary care staffing; allowing for 'what-if' scenarios to be evaluated, and showing projected access performance measures.

2) "The ReThink Health model simulates the behavior of a health system, tracking changes in health status, utilization, and costs and has been used to evaluate five different health reform policy proposals. The results demonstrated that certain options would improve health status but at higher cost and greater health care inequality. Other options were found to improve health status, reduce inequalities, and lower costs. Such divergent outcomes would be extremely difficult to anticipate or quantify without the aid of a simulation model."

Applying Dynamic Simulation Modeling Methods in Health Care Delivery Research—The SIMULATE Checklist

---

Clarify and simplify the rules for purchased care to provide the best value for the patients.[53]
One of VHA's core responsibilities involves providing health care services to eligible Veterans. Although VHA has traditionally carried out its health care role primarily by operating a national network of hospitals and other facilities, the agency also administers a purchased-care function through which it pays for health care services from outside providers (sometimes referred to as purchased care or community care). VHA purchased care has evolved primarily to address situations in which VHA's direct-care resources are unable to offer needed services to Veterans. Although purchased care has accounted for only a small fraction of VHA's health care budget over the past decade, that fraction is growing. In the wake of the recent crises in access to care through VHA facilities, stakeholders and policy makers are revisiting the role and performance of VHA purchased care. Specifically, they are considering whether modifications to VHA's purchased-care approach might be desirable, given broader goals of expanding access to care,

---

[53] This information was presented in RAND Corporation Assessment C (Care Authorities) in Volume II.

---

enhancing trusted partnerships, and improving VHA operations to deliver seamless and integrated support for Veterans' health.

The purchased care landscape is already in the midst of a transformation. Numerous changes to VHA's authorities and mechanisms for purchasing care are being proposed, planned, or implemented. With so many facets of purchased care authorities and practice in flux, the full landscape of VHA purchase care is not just complicated, but dynamically so. Moreover, while the proposed policy changes aim at addressing many different problems and issues, their sheer multiplicity suggests the drawbacks of a piecemeal approach, absent a guiding orientation and strategy for VHA's purchased care enterprise as a whole. To enhance the availability of purchased care to the patient, VHA should:

- Develop a stronger management structure for purchased care and allocate responsibility and authority to the most appropriate levels. VHA purchased-care activities require improved program management, with responsibilities assigned to organizations at the appropriate level of VHA's administrative hierarchy.

- Establish an ongoing process for evaluating third-party administrator performance. VHA should also assess the adequacy of the provider networks, the efficiency of claims and other processes, and Veteran experiences with the programs.

- Develop clear and consistent guidance and training on VHA's authority to purchase care. Existing VHA guidance pertaining to purchased care is scattered, sometimes outdated, and inconsistent in setting clear standards, leaving local facilities to develop their own policies and procedures.

- Ensure that both new and existing purchased-care contracts with outside providers and third-party administrators include appropriate requirements for data sharing, quality-of-care reporting, and care coordination.

> "Today we have seven different programs for providing community care. Each one has its own exclusions, each one has its own payment options. It's incredibly confusing."

5   Operations

Finding 2: Uneven bureaucratic business operations and processes
Recommendation 2—OPERATIONS: Develop a patient-centered operations model that balances local autonomy with appropriate standardization and employs best practices for high-quality health care
Right size and reorient the VHA Central Office to focus on support to the field in its delivery of care to Veterans.
Fix substandard processes that impede the quality of care provided to the Veteran.
Design and implement a systematic approach to identify best practices and disseminate them appropriately across the enterprise.

CURRENT STATE

There is recognized variability in the execution of business operations across VHA. Many VA Medical Centers implement operations differently, resulting in widespread inconsistencies across the organization. Multiple assessments, including Assessments E (Workflow – Scheduling), F (Workflow – Clinical), G (Staffing/Productivity), I (Business Processes), and J (Supplies), found differing approaches to staff management, scheduling, quality measurement, documentation and coding, patient flow, performance management, claims, and purchased care. Multiple assessments also found support functions (e.g., HR, IT, and Contracting) that do not adequately meet the needs of the medical centers in the delivery of patient-centered care. In some cases, the lack of standardization and local variations contribute to the direct and negative impact on the overall Veteran experience and timely access to care. In 2014, the VA OIG reported that a lack of common business rules "has resulted in quality of care deficiencies."[54] In other cases, the assessments found local implementations and best practices that are creating positive outcomes (e.g., shorter length of time to hire); however, when process improvements occur at the local level, they are often not shared or do not scale across other facilities. These widely varying processes also highlight the complexity of the VHA system. Severe problems may manifest themselves at one facility, while another constantly receives tributes from Veterans and health care experts.

To operate effectively and provide the best care to Veterans, VHA needs to increase the empowerment of local leaders while simultaneously increasing the standardization of critical operations and processes. There is a need for greater support and flexibility for those providing care at the local level as well as a need for improved processes to more reliably support Veteran care across the system. Addressing these imperatives simultaneously is not simple. As one senior leader stated, "We can't figure out what to standardize...We tend to standardize everything and nothing at the same time." VHA needs an operating model that will encourage

---

[54] U.S. Department of Veterans Affairs. Office of Inspector General. (2014). Part II: Performance section. Major management priorities and challenges. Retrieved from: http://www.va.gov/oig/pubs/VAOIG-2014%20MMC.pdf

both standardization and the appropriate level of local autonomy, focusing on providing Veterans with high-quality health care.

Some observed areas in which the current VHA operating model does not support well-defined, consistent, and standard processes—causing variability in the system and possibly resulting in a negative Veteran experience—include the following:

- The length of the HR-directed hiring process for all VHA staff was cited as a challenge in 100 percent of 19 staffing workshops conducted by Assessment F (Workflow – Clinical). The VHA hiring timeline significantly exceeds private-sector benchmarks, affecting VHA's ability to fill vacancies on patient care teams. VHA targets 60 days from receiving a request for a job posting to making a tentative offer, but it does not include the steps needed and time required to make a final offer. Interviewees and workshop participants consistently reported that hiring exceeds the 60-day target, reaching approximately six months for most clinical occupations.

- As Assessment E (Workflow – Scheduling) found, many private-sector systems have adopted larger, more centralized scheduling call centers that have lower per-unit costs; put less stress on space-constrained care facilities; and are able to offer more coaching, training, and career options to schedulers. Some of these have resulted in significant improvements. Since 2008, for example, Cleveland Clinic's centralized scheduling call center has enabled a 28-percent decrease in abandoned calls, a decreased scheduling error rate, increased physician utilization of scheduling templates, and a 12-percent increase in the number of patient visits. That organization believes it was "able to capitalize on economies of scale," scale that should be available to VHA.[55] But VHA scheduling call centers, where they exist, are operated at the VAMC level to address local needs. These call centers are not tracked or coordinated on a national scale, and there is no centrally available information about VHA's scheduling call centers, including how many call centers exist, what functions they serve, or how many schedulers they employ. As one interviewee suggested, "It would be nice to know where else there are [scheduling] call centers and talk to them." Since these centers are not tracked or coordinated, there is no effort to share best practices. In response to a data call generated by Assessment E, the vast majority of schedulers operate in clinics with only a small percentage actually operating in what VHA considers call centers. The call centers that do exist tend to be fairly small, with a median size of 12 schedulers, compared to most private-sector health systems that have an average of 28 agents. In response to the same data call, VA facilities reported that the average speed of answer (ASA) was 79 seconds and the average abandonment rate was 11 percent. In comparison, average private hospital call centers achieve a 32-second ASA and a 5.15-percent abandonment

---

[55] Rodak, S. (2013, August 8). Cleveland Clinic's call center improves care access. *Becker's Hospital Review*. Retrieved from http://www.beckershospitalreview.com/capacity-management/cleveland-clinic-s-call-center-improves-care-access.html

rate.[56] On average, Veterans are waiting longer to reach a VHA scheduler and give up at a greater rate than private-industry patients.

- Assessment J (Supplies) indicates that the organizational structure of VA's supply chain enterprise is unduly complex and duplicative. VA and VHA both contain multiple organizations that play a role in managing VA's medical supply chain and, as a result, there are areas of overlap and tension between involved groups. There is a recognized stovepiped and fragmented structure with a lack of clarity on roles and responsibilities. VA's IT and data systems in the supply management area are also antiquated, not integrated, and they do not meet the needs of a modern health system. There are multiple instantiations of the underlying architecture for VA's clinical, procurement, and inventory management systems, each with its own product nomenclature and numbering system as well as extensive free-text entries. As a result, efficient and effective cross-site comparisons or regional and national rollups are not feasible. VA's current inventory management does not have a feedback loop that links inventory to product utilization, contracting, ordering, and vice versa. This prevents optimal use of the Medical Surgical Prime Vendor program and prohibits more effective volume-based national or regional contracts. VA has not taken full advantage of its scale or potential for product standardization to achieve optimal pricing and efficiency. An analysis of unit prices for facilities across two VISNs showed significant variation in price paid for identical items.[57] For example, the highest price paid for a commonly used disposable blood pressure cuff was more than twice the lowest price. An analysis of purchase order data shows that 38 percent of purchases are made on a government contract, with the remainder through open-market purchasing. VA's supply purchasing systems are not integrated with contract or pricing catalogs, requiring the buyer to research whether an item is on contract and, if so, through which contract a purchase should be made. Several buyers reported that they bypass this step and buy products through the channel that is most familiar and convenient rather than potentially exploiting new contracts and pricing arrangements. VA also has limited ability to monitor and drive compliance with contract requirements because the required data are not captured electronically. More than 60 percent of all clinical supply items do not have a contract number listed.[58] Finally, VA does not have a mechanism to identify products for which central contracts should be established.

Exacerbating these challenges is the recognition that, as Assessment L (Leadership) identifies, VHA Central Office (VHACO)—consisting of a series of individual, highly unintegrated program offices—does not yield the coordination and collaboration required to support the field in its delivery of care to Veterans and adequately address the variability in the system. VHACO has experienced dramatic growth in the number of program offices and staff over the past five years, with VHACO program office full-time equivalent (FTE) growth vastly outpacing the

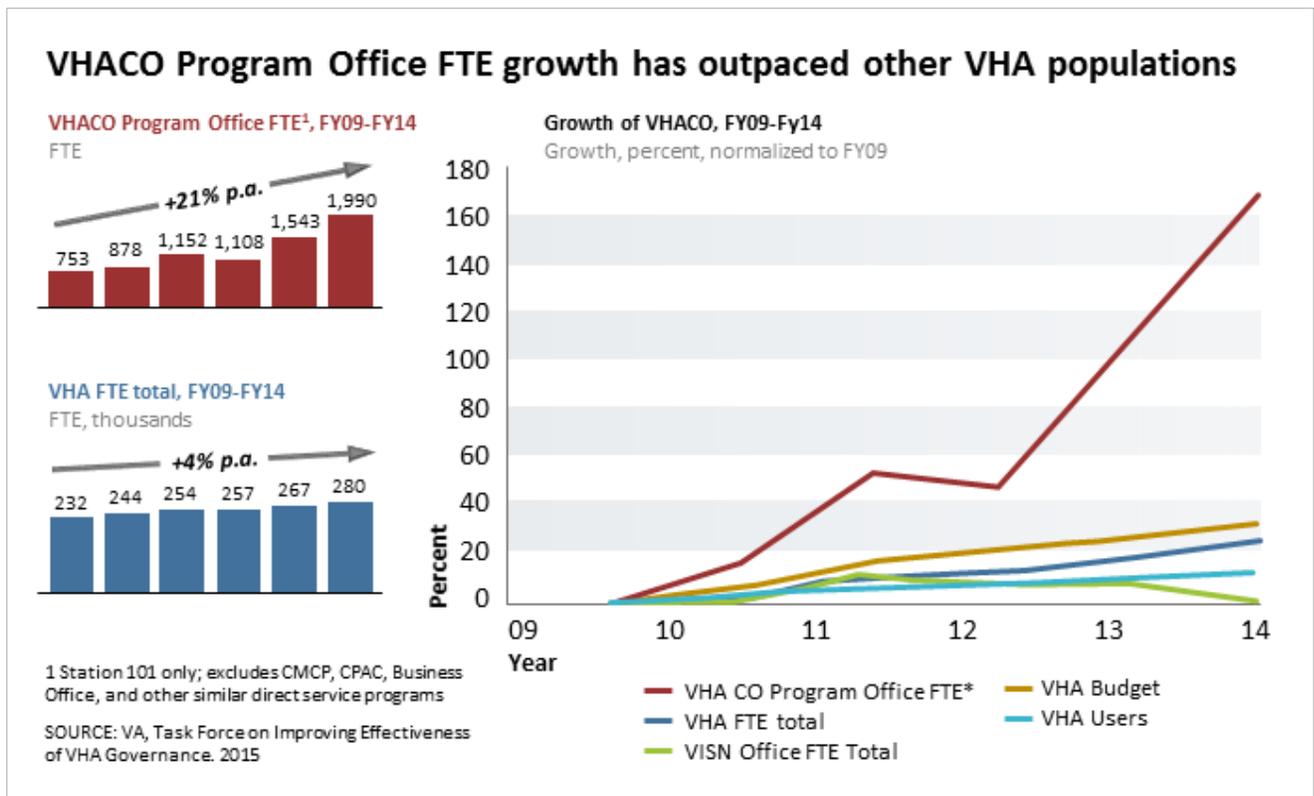
growth of total VHA employee population and Veterans served (Figure 6).[59] However, in spite of program office growth, there is little systematic effort to coordinate or integrate efforts and initiatives, and there has been no discernible improvement in business or health outcomes in VHA as a result of this growth.[60] Instead of alleviating the administrative burden on the field, the growth of VHACO has had the inverse effect, creating an environment where the field is serving VHA Central Office.

Figure 6. VHACO Program Office FTE Growth


Further, the Central Offices—VACO and VHACO—are not playing a key and necessary integrator role to help spread best practices across the organization. [61] While pockets of best practices and innovation exist, the assessments found the adoption of best practices to be isolated, sometimes even within the same facility. While in many cases local best practices and innovation are allowing specific VAMCs to maximize operational efficiency and positive Veteran experience, these best practices are not systematically shared and adopted across VAMCs.

[59] U.S. Department of Veterans Affairs (2015, February 28). Task Force on Improving Effectiveness of VHA Governance: Report to the VHA Under Secretary for Health.

[60] U.S. Department of Veterans Affairs (2015, February 28). Task Force on Improving Effectiveness of VHA Governance: Report to the VHA Under Secretary for Health.

[61] The information in this section is derived from McKinsey & Company Assessment L (Leadership) in Volume II

"As best the Task Force could determine, the addition of new program offices occurred on the basis of ad hoc decisions by VHA leadership. There was no systematic review by an internal resource committee or by NLC [National Leadership Council] committees for which they were responsible and there was no systematic review to determine if they had been successful in improving organizational outcomes. Similarly, there was no process for systematically reviewing requests for additional [full-time equivalent] or resources for a given office. Finally, there was no process at the organizational level such as review by the collective senior VHA CO leadership, by the resource committee, or by the NLC itself for formulating clear recommendations on how much funding from the VHA budget was to be set aside for VHA CO program offices versus allocated to the field for providing direct care to Veterans."

Task Force on Improving Effectiveness Of VHA Governance:
Report to the Under Secretary for Health

As one previous assessment of VHA points out, "There is no mechanism for sharing scheduler tips and best practices for using the systems or to improve scheduling activities. Seasoned schedulers share their insight and lessons learned by word-of-mouth."[62] A recently published internal VHA report titled "Task Force on Improving Effectiveness of VHA Governance—Report to the VHA Under Secretary for Health" reached a similar conclusion. As that report suggests, "there has been little or no ongoing effort to share best practices or standardize procedures among either VHACO program offices or VISN offices."[63]

RECOMMENDATIONS

- Right size and reorient the VHA Central Office to focus on support to the field in its delivery of care to Veterans.

- Fix substandard processes that impede the quality of care provided to the Veteran.

- Design and implement a systematic approach to identify best practices and disseminate them appropriately across the enterprise.

"I'm shameless about stealing what works at other places. The problem is, I don't know what other places are doing. We need a way to connect, to learn from each other."

[63] U.S. Department of Veterans Affairs. (2015, February 28). Task Force on Improving Effectiveness of VHA Governance: Report to the VHA Under Secretary for Health.

Right size and reorient the VHA Central Office to focus on support to the field in its delivery of care to Veterans.[64] As Assessment L (Leadership) concludes, VHA should adjust the balance of control and empowerment across all levels of the organization by clarifying decision rights, offering greater role clarity, empowering leaders, and encouraging appropriate risk taking. VHA should refocus the role of VHA Central Office to managing outcomes and providing support to the field. Specifically, VHA should clarify the roles and responsibilities of each major operating unit: VHACO, VISNs, VAMCs, community-based outpatient clinics (CBOCs), and other organizational units. Once this clarification is achieved, the VHA Central Office should focus on enhancing collaboration, supporting resource prioritization, executing certain centralized functions, ensuring alignment with strategic direction, and, most importantly, supporting the field. The intent of this is to move from a series of individual program offices issuing independent directives and action items, with few mechanisms to encourage coordination, to a much smaller number of coordinated primary strategic priorities, or lines of business, around which supporting program offices would be organized and through which supporting program office work would be conducted.

> "Program offices should be a consultancy—a small group of people. There should be more oversight of the Program Offices, because there are turf issues that leave the Field constantly answering to everyone."
>
> *VHACO Leader*

In addition, VHA should:

- Reassess all VHA Central Office-directed metrics and policies to ensure that they add sufficient value to patient outcomes and eliminate those that do not.

- Release process guidance on a regular and routine schedule to medical centers to enhance coordination and to minimize the disruptive effect of new, frequent, and duplicative directives on existing guidance.

- Create policy communication standards that require that any new policy includes a clear rationale tied to desired outcomes, recommended approach, suggested local implementation plan, and sufficient time to implement.

- Increase alignment and coordination between the offices responsible for policy and the offices responsible for operations by actively eliminating the "artificial distinction between policy and ops"[65] that exists today.

- Clarify the decision rights of VACO, VHACO, VISN, and the Medical Center, to include clearly articulating decision rights by level, organization, and role and standardizing where appropriate while allowing for local flexibility based on local needs.

- Define the role and responsibilities of the VISN (or any other local structures being considered), the balance between empowerment and support of medical facilities, and

---

[64] The information in this section is derived from McKinsey & Company Assessment L (Leadership) in Volume II.

[65] (2015). Choice Act assessment interviews with VHA.

the VISN role in coordinating, translating, communicating, and innovating across the system.

- Coordinate with VACO to select a chief information officer (CIO) for VHA to identify and advocate for health IT needs and to measure the value of IT services and capabilities for health care.

- Implement a more participative management approach that engages leadership at all levels in analyzing problems, developing strategies, implementing solutions, and measuring and tracking outcomes. Doing so would create a greater sense of ownership in VHA; instill a sense of commitment, safety, and pride among VHA leaders; create more receptive conditions for implementing change across the organization; and serve as a breeding ground for future leaders. In addition, as one journal suggests, "creativity and innovation are two important benefits of participative management."[66]

Fix substandard processes that currently impede the quality of care provided to the Veteran. The independent assessments provide substantive and detailed recommendations to address many of the operational challenges that impact VHA's ability to provide timely and consistent patient-centric health care. At an overarching level, VHA needs an operating model that provides medical centers with the autonomy and flexibility to innovate and address local needs while also providing standardization across the system to allow for more consistent and efficient delivery of Veteran care. As one VHA senior leader stated, "We need to identify key business processes that have to be standardized, such as scheduling, and standardize those things ruthlessly. We need fidelity in the system to run the business."

In addition to the need for more consistent and efficient key processes, findings support the need for a fundamental overhaul of the core support functions of HR, IT, and Contracting to increase responsiveness and efficiency and improve customer service. These functions should be aligned with the needs of the VHA organizations delivering care to Veterans and hold those organizations accountable to outcome-based metrics to enable timely and effective care. This is consistent with the recent guidance from the Office of Management and Budget (OMB) in response to the Federal Information Technology Information Reform Act (FITARA), which enhances agency CIO authority while requiring that officer to focus on and be explicitly accountable for assuring that agency IT resources support agency mission and programs (i.e., are aligned with requirements of VHA mission and programs). While the scope of the existing statutory provisions address IT, the intent can be extended to other support functions (e.g., Contracting, HR).[67]

The department has already taken some action to address the current deficiencies in VA support functions. MyVA established as one of its five focus areas "Achieving Support Service Excellence," with a stated mission to "optimize the organization, functions, and activities of VA's core support functions that focus on delivery of world-class services to VA facilities and

---

[66] McMillan, A. (n.d.). Participative management. [Website]. Reference for Business. Retrieved from http://www.referenceforbusiness.com/management/Or-Pr/Participative-Management.html

[67] For more information on FITARA, see The MITRE Corporation Assessment H (Health Information Technology) in Volume II.

The views, opinions, and/or findings contained in this report are those of The MITRE Corporation and should not be construed as an official government position, policy, or decision.

organizations that directly serve Veterans." The assessments' findings and recommendations support the following aspects of the "vision of the future" for VA support services as stated in the MyVA Transformational Plan:

- A collaborative process that produces clear business requirements and processes as well as accountable service-level agreements (SLAs) for support services.

- Integrated contracting and supply-chain activities that directly support delivery of Veteran outcomes.

- HR functions aligned to support facility directors with timely hiring, benefits, and employee relations.

- Fully integrated VA-wide information capabilities, supported by IT operational capabilities optimized to meet expectations at point of service.[68]

Design and implement a systematic approach to identify best practices and disseminate them appropriately across the enterprise. To improve overall operational performance, VHA must create a systematic way to identify, share, and scale the solutions and best practices achieved by its top performers and those of other organizations. Coordinated reviews and assessments of identified best practices should be conducted to determine if the practices are scalable across the organization. The VHA Central Office should provide strategic guidance and should support establishing and implementing the approach. It would then be an appropriate role of the VISN to lead the best-practice identification and to share ideas within and across the enterprise, working collaboratively with VAMC leaders and staff. A clear example of the impact of such an approach was observed in VISN 4 as described in Figure 7.

While VHA has numerous assets in place to identify and spread innovation and best practices, these resources have not taken hold. VHA's current culture and organizational structure, which allows for differing VISN business models, do not support standardization or effectively leveraging best practices on an enterprise basis. VHA should strive to standardize when it can and enable variation and innovation when it should. The National Leadership Council, or another identified advisory board, must be empowered by senior leadership to systematically review and consider which best-practice assets support and align to strategic outcomes such as Veteran satisfaction and access. In performing this review, the advisory board should consider the following:

- Integrating best practices with performance management and encouraging collaboration across VAMCs; those medical centers that are not performing as well as others should be encouraged to adjust their processes by leveraging others' approaches.

- Developing an implementation strategy that migrates best practices from high-performing to lower performing facilities.

---

[68] U.S. Department of Veterans Affairs. (2015, April 14–15). MyVA Advisory Committee: Inaugural meeting [PowerPoint slides].

- Evaluating the current use and efficacy of the Virtual Learning Center (VA's current online database with shared innovations, best practices, and lessons learned from VAMCs and CBOCs) for capturing and disseminating best practices.

- Developing criteria for rationalizing the best practices that should be performed at a local versus regional or enterprise level. For example, where national economies of scale can be achieved versus where local issues (e.g., demographics) prohibit broader application.

The above recommendations recognize that the best practices found in one facility or VISN will be an excellent source of inspiration and guidance for their peers, but it is important not to expect every best practice to be equally effective or implemented exactly the same way in every location.

Figure 7. VISN 4 Best Practices

This page intentionally left blank.

6   Data and Tools

Finding 3: Non-integrated variations in clinical and business data and tools
Recommendation 3—DATA and TOOLS: Develop and deploy a standardized and common set of data and tools for transparency, learning, and evidence-based decisions
Use standardized clinical and administrative data for accuracy and interoperability.
Implement a single, integrated set of system-wide tools centered on a common electronic health record (EHR) that is interoperable across VHA and with DoD and community provider systems.
Transparently share performance metrics for leadership, clinical, and business functions across VHA to identify and adopt best practices for continuous improvement.

CURRENT STATE

Multiple assessment efforts identified challenges in collecting, managing, and effectively using data:

- A lack of standard, interoperable enterprise VHA systems and tools negatively impacts VHA's operations and resulting data.

- The quality of data and multitude of metrics limit VHA's overall performance and continuous improvement efforts.

- VHA lacks a holistic, enterprise approach to managing, collecting, and leveraging its data.

In addition, Assessment H (Health Information Technology) identified several key challenges in VA's use of information technology. Inadequate collaboration between VA's centralized IT organization and VHA has precluded the implementation of capabilities that support VHA health care needs. Due to excessive project management overhead, a complex legacy IT infrastructure that is difficult to modernize, and more than 130 variations of the primary software system deployed across VHA medical facilities, the implementation of improved IT capabilities in the last 10 years has been extremely limited. During that time frame, VA applied the majority of its development resources to HealtheVet and the integrated EHR (iEHR) projects, both of which failed to provide the expected results. This delayed further development and improvement of VistA and CPRS so that they are no longer leading-edge products and are in danger of becoming obsolete. Scheduling, telephone, and billing systems have stagnated, and there is no strategy and roadmap for scheduling initiatives across VA that integrates Veteran access to scheduling via phone, telehealth, and mobile apps. Inconsistent and ineffective data collection across VA medical facilities has prevented evidence-based assessments that would inform capability improvements. VA is falling significantly behind the private sector in using data to improve all aspects of Veterans health care.

Enterprise Data: VHA's operational environment is plagued by a significant level of fragmentation and a lack of standards. Data aggregation across the entire VA system is problematic when each system either lacks standards or conforms to different, local data

standards.[69] This constrains VHA's ability to recognize organizational trends, identify best practices, and assess the effectiveness of health care delivery services across the entire VHA system. Efforts to access data in support of these assessments illustrated some of the issues plaguing the operational environment. Several data discrepancies and data quality issues were noted. Some data routinely maintained by other health care systems were simply not available.[70] Three different VHA sources had to be accessed to obtain lab data. Each source resulted in a different answer, and various groups within VHA did not know how to reconcile these three sources or which source provided the most accurate information.[71]

The impact of these enterprise data issues was evident across various assessments.

- VHA maintains several different systems to manage access and flow; however, a lack of integration across systems, inconsistent methods for tracking data, and gaps in key flow metrics results in highly variable, non-actionable demand and capacity data. While the National Bed Control Database showed that 81 percent of one VAMC's inpatient beds were operational, that facility reported that only 51 percent of its beds were available for patients due to unreported staffing and construction-related bed closures.[72]

- Systems limitations often demand manual processes that can obviously reduce the timeliness and accuracy of data and obscure the true state of VHA's activities. In FY2014, 28.6 percent of claims for non-VHA-provided care were submitted via Electronic Data Interchange, versus a 94-percent benchmark for commercial claims in civilian practice.[73] Significantly relying on manual processes slows collections and payments activities and introduces errors and waste into the process.

- There is a lack of quality, system-wide data for developing predictive models to prospectively match provider availability with patient needs.[74] Such models are built on important inputs (such as aggregated views of provider availability) and allow

> "Greater issue is lack of standardization of code sets. One aspect of data standardization is in lab tests—any given site may name it any number of ways, ex. hemoglobin tests. That site may know what it means. When you roll it up nationally—have a lot of variability. Reference ranges can be different. Different sites use different lab instances."

for important activities, including assessing the likelihood of patients missing appointments (so that they can be targeted for more proactive individualized appointment reminders or other interventions to increase likelihood of appointment completion); aggregated views of provider availability; and facility-centralized patient reminder systems across multiple modalities. Thus, this lack of data and data management systems compromises the ability to maximize provider availability for treating patients.

- Measuring each health care provider's productivity is challenged by several issues. First, while work Relative Value Units (wRVU) are "the current tool for physician productivity measurement in the clinical arena, a more complete productivity measurement would capture the sum total of a physician's contribution."[75] For example, the wRVU does not reflect patient satisfaction with the encounter or the provider's effectiveness in improving the patient's health outcomes. The accuracy of productivity, when measured by wRVUs, is dependent on accurate and thorough coding and documentation practices; during site visits, assessment teams observed a general lack of local infrastructure to assist providers and nurses in accurately and comprehensively documenting all encounters.[76] VHA does not capture FTE-level information for its fee-based care providers, which limits its ability to systematically track fee-based provider productivity. The proportion of clinical workload generated by fee-based physicians represents 13 percent of all physician workload and may be higher at smaller facilities where fee-based providers can be a greater proportion of specialty care provided. VHA uses multiple standards to measure its primary care panel size that rely on local interpretations of policy and a range of situational factors (for example, whether the panel is a specialized panel such as geriatric or home-based primary care, and adjustments for new providers based on start dates).

- VHA also lacks the data governance to define and implement standards and business rules to ensure consistent data definition, integrity, and documentation. During the course of our assessments, documentation related to VHA's data also presented issues. Dozens of sources of documentation describing the various types of data are scattered throughout VHA. This requires analysts to sift through many different intranet sites and encounter totally different documentation styles with varying levels of usefulness.

Enterprise Tools: Discussions with industry executives identified a number of system capabilities that are essential to operating a high-performing health care system, to include a common electronic health record (EHR) and tools that enable scheduling, billing, claims payment, and patient-centered navigational tools.[77] Standardizing these capabilities and implementing them at an enterprise level results in information and care continuity, cost

[77] Several health executives also highlighted the need for an Electronic Medical Library (EML) that includes a single set of clinical care protocols. VHA's EML was not assessed as part of this effort.

---

savings, and consistent care delivery and business processes. The strategy should be standard across the enterprise wherever and whenever possible, and vary locally when needed. The timely and accurate enterprise data produced through these system capabilities are of particular importance as they provide the means to optimize the overall performance of the health care system. In addition, the potential of dynamic simulation modeling to underpin decisions enabling the delivery of health care is increasingly being realized and should be exploited. Our findings related to each of these important components is discussed below.

- **Electronic Health Record**: An EHR represents the core of VHA's VistA system. As outlined in Assessment H (Health Information Technology), customized implementations of VistA at the VAMC level that do not all employ standard data elements and algorithms has resulted in approximately 130 instances of VistA across VHA, leading to a complex, heterogeneous mix of hardware and software, which impedes developing and deploying system changes and new capabilities and raises operations and maintenance (O&M) costs. Those instances are not well documented, further complicating efforts to upgrade and maintain the system and to conduct end-to-end testing outside of the operational environment. VHA's EHR issues stymie interoperability between VHA facilities as well as with DoD and non-VA providers. Multiple assessments noted the lack of interoperability resulted in incomplete patient records with potentially significant implications for the Veteran and VHA. This is not a trivial issue, and multiple solutions have been attempted over the last several years without success. Nevertheless, it remains a crucial issue. Incomplete records introduce unnecessary clinical risk, complicate the transition from DoD to VHA care, and inhibit VHA's ability to bill and collect revenue accurately and timely.[78]

- **Scheduling**: VistA is also VHA's primary scheduling tool. As highlighted in Assessment E (Workflow – Scheduling), VHA scheduling tools do not provide facility staff with the capability to effectively match patient requirements to provider availability. In addition, the tools do not provide information that allows clinic management to improve scheduling performance. For example, because providers operate across multiple and sometimes overlapping clinic schedules, also known as "profiles," calculations of aggregate appointment slot supply and therefore appointment slot utilization rates are not always correct in clinic access reports. VHA has created additional operational processes to address the recognized state of imbalance for supply and demand for appointments. Essentially, staff had to employ additional processes to work around system limitations. Current processes and infrastructure concerning the scheduling systems reduce the ability of clinics to maximize the use of provider time.

- **Billing**: Assessment I (Business Processes) noted significant shortcomings in the systems and tools supporting VHA's billing and collections activities. Technical capabilities typically seen in private health care systems are lacking or absent in VHA. For example,

---

[78] On July 29, 2015, the Department of Defense awarded a contract to a commercial team for "an electronic health record off-the-shelf solution, integration activities and deployment across the Military Health System." See http://www.defense.gov/News/Contracts.

automated tools for providing real-time estimates of out-of-pocket expenses, electronic submission of Veteran payment plan forms, and automated first-party claims matching do not exist at VHA. In addition, Assessment I lists more than 10 systems and tools used to support VHA's billing process. Lack of integration and interoperability between billing systems and tools (e.g., VistA and Nuance) slow billing activities and introduce potential errors in data as staff are required to enter redundant data into different systems. In fact, VA billing staff are manually reviewing 100 percent of claims subsequent to automated claim edits. This manual process is typically limited to 10–20 percent for industry.

- **Claims Payment**: VHA's claims payment activities are similarly burdened by lack of automation, multiple systems that are not integrated, and a significant amount of manual work. Specifically, automation is lacking in VHA's primary claims system, Fee Basis Claims System (FBCS), requiring VHA staff to scan the majority of the paper claims into FBCS and manually adjudicate claims. In addition, non-VA providers do not have

  "As a service-disabled Veteran, I know first-hand the challenges women face during military service and when they return home. I, like many women who served, did not understand on leaving military service the benefits and services to which I was entitled, despite the fact that I suffered an injury during my service as an Army medic."

  Disabled American Veterans Deputy National Legislative Director Before the Committee on Veterans' Affairs

  U.S. House of Representatives

  April 30, 2015

  visibility into the status of their claims. FBCS does not support certain types of claims for non-VA care, and these claims must be processed through VistA. Overall, the high reliance on manual processes slows payments activities, introduces potential errors (e.g., lost claims and misrouting of claims), and introduces waste into the process (e.g., providers filing duplicate claims due to delays in payment and a lack of easy visibility into their status). In addition, such reliance on these manual processes reduces the timeliness and accuracy of data and obscures the true state of VHA's financial activities.

- **Patient-Centered Navigational Tools**: The *Voices of Veterans* report, published by VA's Center for Innovation in November 2014, lists two of its key themes as "Many Veterans don't know what benefits are available to them, or how to access them" and "Utilizing VA

  "Almost everything I find out is either from another Vet or by accident."

  2014 Wounded Warrior Project Survey Report of Findings

---

technology has severe limitations with some bright spots."[79] The benefits available to the Veteran can be complex and difficult to understand. Making matters worse, the current suite of options and the navigational tools to explore available benefit options have proven challenging. Data presented by the MyVA initiative provide some perspective on the magnitude of this challenge, identifying more than 1,000 VA websites and more than 900 1-800 numbers. Further, Assessment A (Demographics) found that "among respondents of the National Survey of Veterans who report not using VA services, 12.4 percent (1.8 million) report that the barriers to access are a reason for non-use. If these obstacles are addressed, that assessment estimates that an additional 492,000 new patients will use VA for some of their health care needs."[80]

Metrics for Performance Management: VHA lacks a clear strategy to effectively apply its data and metrics to performance improvements, including distilling and prioritizing metrics to drive patient-centered outcomes. As Assessment B (Health Care Capabilities) notes, VHA has more than 500 quality measures to monitor quality of care regionally and locally, concluding that the proliferation of measures creates burdens on staff and resources and can lead to an emphasis on the measures rather than improving areas of care that are more likely to improve patient outcomes. One VACO leader stated, "Our problem is that we're awash in data and don't do anything with it."

The Centers for Medicare & Medicaid Services defines quality measures as "tools that help us measure or quantify healthcare processes, outcomes, patient perceptions, and organizational structure and/or systems that are associated with the ability to provide high-quality health care and/or that relate to one or more quality goals for health care. These goals include: effective, safe, efficient, patient-centered, equitable, and timely care."[81] Among quality metrics, only a subset should be considered performance measures—those quality metrics with attributes rendering them suitable for explicit comparisons of care between institutions or health care providers.[82] Rather than adopting the practice of many high-performing health care systems— where targets are balanced in support of the mission, and a limited number of key metrics are used to measure performance and drive outcomes—VHA has adopted a catch-all approach to performance management. As Assessment L (Leadership) notes, with 382 measures today in its 10-N National Performance Measures Report provided by interviewees, VHA is not setting clear, actionable organizational targets (10N NPRM, 2015). Further, there is widespread recognition of the overabundance of metrics and the need to simplify, with one VAMC director

[82] Bonow, R. et al. (2008, December 9). ACC/AHA Classification of Care Metrics: Performance Measures and Quality Metrics. *Journal of the American College of Cardiology 52*(24), 2113–2117. doi: 10.1016/j.jacc.2008.10.014

describing his perception of VHA's approach to setting performance measures as, "If 50 metrics are good, 100 must be better."

Ironically, the sheer number of performance measures and the limitations of the current performance management process make effectively tracking performance difficult. One of the VISN's roles is to ensure that performance targets are negotiated with VHACO and are being met at the VAMC level. This leads to regularly scheduled meetings with VAMC leadership to review binders of performance reports and requests for detailed corrective action plans when a measure needs improvement. These progress reviews generally focus on the weakest performance measures, contributing to a commonly held perception that metrics are used to identify weak performers rather than to help drive performance excellence.[83]

"Moving away from blame allows an organization to learn from mistakes and conduct systematic improvement efforts based on that knowledge."

Bringing a Systems Approach to Health

This emphasis on those not meeting performance targets extends to reviews conducted by multiple internal and external organizations. The bureaucratic and highly politicized environment within which VHA operates has led to a dramatic increase in the number of assessments, administrative investigation boards, and root cause analyses of VAMC performance. This focus has led many of those interviewed to describe VHA's culture as "punitive" rather than constructive or incentivizing. While understanding where VAMCs are not working well is important, this focus on poor performers is limiting from a systems perspective because it does not expose the systemic findings or potential solutions. It is equally important to understand where things are going well and the lessons that can be drawn from those high-performing sites, where successful systematic improvements and best practices are taking place.

RECOMMENDATIONS

- Use standardized clinical and administrative data for accuracy and interoperability.
- Implement a single, integrated set of system-wide tools centered on a common EHR that is interoperable across VHA and with DoD and community providers.
- Transparently share performance metrics for leadership, clinical, and business functions across VHA to identify and adopt best practices for continuous improvement.

Use standardized clinical and administrative data for accuracy and interoperability. VHA must take a more comprehensive approach toward managing its data. A key prerequisite for an effective data management strategy is clarifying the demand expectations to inform the direction and priorities of the data strategy. With that direction in place, VHA's data management strategy should include:

---

[83] This information is presented in McKinsey & Company Assessment L (Leadership) in Volume II.

- Identifying, rationalizing, and prioritizing VHA's data needs and uses enabled by common definitions and document templates

- Identifying the internal and external data sources and analytical products required to address these needs and assessing the sources and analytical products relative to users' requirements (timeliness, accuracy, completeness, volume)

- Implementing more formal management structures and tools to bring control to VHA's data environment (governance, standards, documentation repositories)

- Identifying potential resources to support the effort (budget, staff, tools)

- Defining an implementation strategy that sets a realistic path toward improving VHA's data environment—acknowledging and working within VHA's current challenges (existing issues with enterprise data).

Implement a single, integrated set of system-wide tools centered on a common electronic health record (EHR) that is interoperable across VHA and with DoD and community providers. Specifically, VHA should implement one-system wide:

- EHR system that is interoperable across the entire system and with DoD and community provider systems, beginning with a cost-versus-benefit analysis performed by VHA between a commercial off-the-shelf (COTS) EHR and the current VistA EHR

- Electronic claims payment system to pay for outside services

- Billing system to collect from other payers

- Patient-friendly scheduling system with modern, single toll-free-number call-center support

- Set of electronic decision support tools describing standard work housed in an electronic medical library.

Along with standardizing VHA processes as discussed in Section 5, a single, integrated set of common system-wide tools centered on an EHR will substantially help address the above issues. In addition, well-designed and developed systems and tools will help VHA enforce and automate business rules, allowing for greater process standardization and reducing variation across VHA. The VA and VHA CIOs should transform the VA IT strategy to a model based on best practices for enterprise IT services that will provide the capabilities that support improved governance, operations, leadership, health care quality, and patient satisfaction. VHA should consider the following recommendations:

- **In partnership with the VA CIO, the VHA CIO should oversee a comprehensive cost-versus-benefit analysis between a COTS EHR and continued in-house custom development of the VistA EHR currently in use**. As Assessment H (Health Information Technology) noted, the analysis should take into account all the complexities of the VistA and CPRS architecture and infrastructure and known issues with performance, scalability, extensibility, interoperability, and security. It should also address full life-cycle costs, including development time (based on recent delivery trends), availability of development resources, maintenance and licensing costs, and infrastructure costs. The VA and VHA CIOs should conduct site visits and review the successful IT practices

implemented at high-performing health care organizations (including VISN 4) to inform their strategies for effective approaches and potential contributions that IT can provide to improve the treatment of Veterans today. Those approaches would address the challenge of providing billing and claims processing capabilities beyond what the existing VistA and CPRS currently provide.

- **Focus on automation, integration, and interoperability for billing and claims.** As outlined in Assessment I (Business Processes), VHA initiated its Health Care Payment System (HCPS) as a replacement for FCBS to serve as VHA's centralized claims processing system and to address many of the issues outlined above. The system is approximately two-thirds complete; however, further development has been stalled by funding issues. VHA should resolve the HCPS funding issue to ensure that this needed functionality is delivered. An effort similar to HCPS is also necessary for VHA's billing process. Assessment I identifies a number of specific capabilities required for VHA's billing system, such as integration across patient intake, medical records, coding, and billing systems; single sign-on capability; automated first-party claims matching; real-time estimate of out-of-pocket patient expenses; and automation to support algorithmic edits and claims correction.

- **Align patient-centered navigation efforts to the MyVA initiative**. In November 2014, VA announced the MyVA initiative to reorganize VA to better serve its Veterans. As stated by Secretary McDonald, "The reorganization, to be known as 'MyVA,' is designed to provide veterans with 'a seamless, integrated and responsive customer service experience—whether they arrive at VA digitally, by phone or in person.'"[84] Central to this theme is enhancing the Veteran experience, approaching the Veteran holistically (e.g., as one VA organization versus three administrations, independent of the channel used) and simplifying and facilitating their use of VA services. From a technology perspective, VHA currently supports its Veterans through a variety of channels, including kiosks located at facilities, call centers, web portals such as My HealtheVet, and mobile applications. VHA must identify and review the tools and channels used to support its Veterans and determine how these tools align with the MyVA initiatives and principles. Based on this assessment, VHA may need to drop, enhance, or expand VHA systems and tools or potentially adopt systems and tools being developed as a part of MyVA.

Transparently share performance metrics for leadership, clinical, and business functions across VHA to identify and adopt best practices for continuous improvement. VHA lacks a clear strategy for its performance measures.[85] As with its enterprise data management strategy, VHA must align its performance management strategy with its clarified mission. As VHA clarifies and focuses its mission, VHA must revisit its performance management approach to ensure that metrics are strategically aligned to the organization's outcomes and that timely and accurate

---

[84] Daly, M. (2014, November 10). VA announces "MyVA" plan, largest reorganization in department's history. PBS. Retrieved from http://www.pbs.org/newshour/rundown/va-announces-myva-plan-largest-reorganization-departments-history

[85] These recommendations are derived from McKinsey & Company Assessment L (Leadership) and several other assessments.

---

data are available to support those metrics. VHA should consider the following in its performance management strategy:

- Focus and simplify metrics to clarify accountability and mission alignment. VHA should develop an integrated and balanced performance scorecard for VAMCs, focusing on a smaller number of core metrics that roll up to support the broader enterprise view. These metrics should focus on the mission, encourage cross-functional collaboration, and be carefully cascaded. This requires eliminating obsolete metrics while continuing to exploit the progress achieved with the Strategic Analytics for Improvement and Learning (SAIL) initiative.

- Evolve performance management along with enterprise data improvements. Given current data limitations, an effective performance management system will be limited in its ability to support leadership. Performance management relies on data that is trusted by those being measured. As the timeliness, accuracy, and consistency of VHA's data evolves, so can VHA's performance measures.

- Monitor the impact of the performance management strategy and the behaviors it promotes. Unrealistic performance targets may disengage staff or worse—they could result in unintended consequences or undesirable behaviors. At the high-performing health care systems that were visited, the use of performance management metrics that were aggressive and frequently not being met was

> "Performance goes down when there are more measures. We need to get away from the spreadsheet and closer to the action. Facilities need coaches—not just shaking a finger and saying, 'Can't miss this.'"
>
> *VHACO Leader*

discussed. Rather than apply punitive measures, these health care systems focused on achieving an overall trend in increasing organizational performance or operations within a specific range. The organizational performance metrics also served as an effective means of identifying those best practices that were enabling these organizations to demonstrate continuous improvement.

- Review industry standards to provide further transparency. Ultimately, VHA is responsible to the Veterans it serves and the public that funds its operations. In developing its performance management approach, VHA must also consider how it can further its accountability and transparency. VHA's SAIL data are a positive start, as they do align with nationally accepted metrics that provide for facility-level, industry comparisons. However, VHA must go further and should review industry benchmarks with the intent of more fully aligning its metrics with industry standards. This would provide greater transparency and would highlight opportunities to adopt industry best practices.

7   Leadership[86]

Finding 4: Leaders are not fully empowered due to lack of clear authority, priorities, and roles
Recommendation 4—LEADERSHIP: Stabilize, grow, and empower leaders; galvanize them around clear priorities; and build a healthy culture of collaboration, ownership and accountability
Push decision rights, authorities, and responsibilities to the lowest appropriate level throughout the organization.
Build on Veteran-centered behaviors to drive a culture of service excellence, trust, continuous improvement, and healthy accountability.
Revitalize the leadership pipeline through establishment of enterprise-wide, comprehensive succession management and leadership development functions.
Strengthen the appeal of senior leadership positions by pursuing flexibilities in hiring and compensation.
Establish sustained leadership continuity by extending tenure for key positions.

CURRENT STATE

VHA is in the midst of a leadership crisis. Through the course of more than 300 leadership-focused interviews and the analysis of multiple employee survey instruments, Assessment L (Leadership) developed a picture of an environment that is challenging and disempowering for current leaders. (A full treatment of VHA's leadership issues is provided in Assessment L.) This environment discourages emerging leaders from seeking promotion within the system. And while there are many resilient leaders working to make a positive impact on our nation's Veterans, they too often achieve desired outcomes despite the challenges of the system within which they operate. The VA staff assessment of their work environment is reflected in the federal government's "Best Places to Work Survey." Since 2010, both VA and VHA have scored lower than the large agency median and both received particularly low ratings in 2014 during the height of the scheduling crisis. Consider the following:

Mission: The lack of clarity of mission expectations, as discussed in Section 4, has resulted in confusion around leadership priorities and VHA's strategic direction. As one VHACO leader expressed, "We need to first figure out what business we want to be in…[and] choose leaders specifically for the need, change, strategy [we've] decided on." Clarifying the mission and expectations serves as a precursor to many critical leadership decisions.

Misaligned Accountability and Authority: VAMC leaders clearly understand that they are accountable for every aspect of a Medical Center as experienced by patients, employees,

---

[86] The information in this section is drawn primarily from McKinsey & Company Assessment L (Leadership) in Volume II.

oversight entities, and external stakeholders; however, they do not feel they have the authority required to fully perform their role in the current environment. A standard VA Medical Center Director position description includes the provision that a Director "operates on a broad

> "It is very much a rule by 'You shall' edicts—I am told the exact number of people I will hire and the jobs that they need to do—even if I don't have a need for the policy or the people."
>
> *Physician Leader*

delegation of authority with independence of action to manage the Medical Center."[87] In both perception and practice, however, this written expectation of delegated authority does not match reality; instead, it is replaced by a fragmented environment with numerous internal and external entities possessing or competing for control. Internally, the VHA organization is viewed as being intensely, unnecessarily complex due to a lack of a clear operating model (as

highlighted in Section 5), limited role clarity, fragmented authority, and overlapping responsibilities. This lack of clarity around operating model, roles, and responsibilities extends across VAMCs, the VISNs, and VHACO.

> "...nobody feels safe, including us. How am I supposed to role model psychological safety when I don't feel safe myself?"
>
> *VAMC Leader*

A complicated external environment exists for VHA, as the organization is treated by oversight entities and external stakeholders as both a hospital system and a traditional government agency, and Congress sees itself in the role of the VHA Board of Directors.[88] An increase in centralized control intended to mitigate risk has in fact constrained leaders' authority. Communications from Congress, VACO, VHACO, and VISNs tend to be overly prescriptive directives governing many aspects of operating a Medical Center. A general lack of clarity around roles and responsibilities contributes to poor coordination across entities and levels, resulting in duplication, communication breakdowns, and functional responses too slow to meet mission needs.

Culture and Environment: Although the broader VHA culture includes a deep commitment to mission at all levels of the organization, it is also characterized by risk aversion and distrust, resulting in an inability to improve performance consistently and fully across the system. At almost every facility visited, at least one leader interviewed mentioned that risk aversion and a reluctance to "speak up" were a significant issue. Three out of every four leaders interviewed at

---

[87] U.S. Department of Veterans Affairs. Veterans Health Administration. Job Announcement: Health System Administrator (Medical Center Director) (VA Job Announcement Number: VASES151407823LR). Retrieved from https://www.usajobs.gov/GetJob/ViewDetails/403947600

[88] Clark, C. (2015, April 30). Senators Propose Acting as "Board of Directors" for VA. Government Executive. Retrieved from http://www.govexec.com/management/2015/04/senators-propose-acting-board-directors-va/111613/

VISNs echoed this concern.[89] This culture permeates across all levels—from the front lines to Medical Center leaders to people at the VHA Central Office—and it contributes to a lack of innovation and best-practice dissemination across the organization. VHA's *Blueprint for Excellence* lists *Provide a Psychologically Safe Environment for Employees* as a key transformational action.[90] However, although psychological safety is acknowledged as a challenge, the broader culture of distrust and risk aversion will not improve until leaders themselves feel safe and can actively demonstrate the desired behaviors.

Leader Preparation: Mission focus alone is insufficient to attract top-notch leaders to the organization or motivate high potentials to seek promotion to senior leadership positions in the current environment. In fact, many current VHA leaders perceive the risk of advancing to significantly outweigh the potential reward. The lack of a comprehensive approach to leadership development and a complete lack of formalized succession planning results in an inability to identify potential leaders and prepare them to assume their future roles.

Compensation is clearly a disincentive for many experienced senior medical health leaders to enter the VHA system,[91] and it remains a point of contention among those leaders who are already in VHA. Some leaders spoke freely about their current salary and how it compares to their peers' salaries in medical centers outside VHA. Ironically, there is a perceived disincentive for Chiefs of Staff and other clinical leaders to aspire to VAMC Director or any other Title 5 (non-clinical) leadership positions, as clinical leaders hired under existing Title 38 authority are granted more flexibility in hiring, compensation, and performance evaluation in their current positions.[92] A VAMC Chief of Staff echoed his peers and offered, "If I became the Director, I would take a $100K cut."[93]

> "The salary is $187,000 [sic] for a medical center director. In private industry, a director could get $600,000. They don't do it for the money, but they need some reward for doing well."
>
> *Acting VAMC Associate Director*

All of these factors have contributed to an anemic leadership pipeline that does not support VHA's existing or future needs. Assessment L (Leadership) paints a dire picture of the current vacancy situation:

---

[89] This information is derived from McKinsey & Company Assessment L (Leadership) in Volume II.

[90] U.S. Department of Veterans Affairs. (2014, September 21). *Blueprint for Excellence: Veterans Health Administration*. Retrieved from http://www.va.gov/HEALTH/docs/VHA_Blueprint_for_Excellence.pdf

[91] This information is derived from RAND Corporation Assessment B (Health Care Capabilities) and Grant Thornton Assessment G (Staffing/Productivity), both in Volume II.

[92] Under the Title 38 employment system, VA has considerable hiring flexibility. It can hire professional employees directly and has flexibility to remunerate Title 38 employees at levels that are consistent with such staff's professional qualifications. Promotions under the Title 38 system are awarded by review panels comprised principally of clinical peers having similar credentials and experience.

[93] The current salary cap for a VA Medical Center Director paid under the SES pay scale is $183,300. Currently, seven Medical Center Directors are compensated under Title 38.

- 39 percent of Quadrad or Pentad senior leadership teams[94] at VHA Medical Centers have at least one current vacancy
- 43 percent of Network Directors are fulfilling the duties of that position in an "acting" status
- 16 percent of VHA Medical Centers do not have a permanent Director (i.e., Acting, Interim, or vacant).

And VHA has been unable to fill these field leadership gaps in a timely manner. The length of time that these openings have been unfilled stretches for greater than seven months on average, with more than half currently open for longer than six months.[95] The tactical, short-term solution to filling VAMC Director positions has been to fill them with Acting or Interim Directors. However, this revolving door of Acting VAMC Directors prevents sustainable change, hurts employee morale, and compromises delivery of care to Veterans in these facilities. One VAMC leader expressed frustration with this current practice, saying "We've had no consistency at the top. We've had Acting Directors. There is no permanent body. We need that consistency. The Directors come in with new ideas, but they don't have the time to implement anything." Complicating this challenge is the realization that VHA faces a large and widespread number of potential retirements in key field leadership roles. Fifty-seven percent of leaders in key positions are eligible for retirement.[96] More than two thirds of Network Directors, Nurse Executives, and Chiefs of Staff are also eligible for retirement, as well as 47 percent of Medical Center Directors. There are indications that this retirement threat is beginning to be realized; in FY2014, retirements by VHA employees GS-13[97] and higher increased by 37 percent over the previous five-year average.[98]

> "Accountability is tough when the leadership is rotating (i.e., Acting Director is here 90 days to six months)...There's a perception of 'who's the Director today?'"
>
> *VAMC Leader*

---

[94] A Quadrad leadership team consists of a Medical Center Director, an Associate Director, an Associate Director for Patient Care Services/Chief Nurse Executive, and a Chief of Staff. A Pentad leadership team consists of a Medical Center Director, an Associate Director, an Associate Director of Clinical Operations, an Associate Director of Patient Care Services, and a Chief of Staff.

[95] (2015). Choice Act assessment interviews with VHA.

[96] "Key positions" are defined as VISN Network Director and Medical Center Quadrad leaders (Medical Center Director, Associate Director, Associate Director for Patient Care Services/Chief Nurse Executive, and Chief of Staff).

[97] The general schedule (GS) is the predominant pay scale within the United States civil service, with 15 levels. GS-15 has the highest base salary.

RECOMMENDATIONS

As outlined in Assessment L (Leadership), VHA must stabilize, grow, and empower leaders; galvanize them around clear priorities; and build a healthy culture of collaboration, ownership, and accountability.

- Push decision rights, authorities, and responsibilities to the lowest appropriate level throughout the organization.

- Build on Veteran-focused behaviors to drive a culture of service excellence, trust, continuous improvement, and healthy accountability.

- Revitalize the leadership pipeline through establishment of enterprise-wide, comprehensive succession management and leadership development functions.

- Strengthen the appeal of senior leadership positions by pursuing flexibilities in hiring and compensation.

- Establish sustained leadership continuity by extending tenure for key positions.

Push decision rights, authorities, and responsibilities to the lowest appropriate level throughout the organization. Clarifying decision rights is a critical factor in empowering leaders in the field. VHA should articulate decision rights clearly by level, organization, and role, standardizing where appropriate while also allowing for local flexibility based on local needs. Clarifying the role of the VISN is particularly important as this role has become unclear over time. This clarification should define key roles and responsibilities, particularly with the local realignment in progress. It must address the necessary balance between empowerment and support between medical facility leaders and VISN leaders. This must be done in the context of overarching systems and clear standard performance goals and outcomes.[99]

Build on the existing commitment to Veteran-centered care to drive a culture of service excellence, trust, continuous improvement, and healthy accountability. Research suggests that "most people won't change their behaviors until they observe the role models in their organization acting differently, and when they see this new behavior positively recognized and rewarded—a clear promotion, a plum assignment, a change in authority or responsibility, or simply praise from the top of the organization."[100] VHA leaders will need to demonstrate desired behaviors with the understanding that culture change will not occur until employees are motivated and feel supported to act differently.

VHA must reinvigorate its mission-driven culture through greater employee collaboration and ownership and by creating a unified organization in support of mission, strategic direction, and a goal of integrated patient care. To do this, VHA will need to foster a culture of continuous improvement and learning, spur collaboration, encourage innovation (within and across the system, and beyond), and connect all employees to the mission. Communications should make

---

[99] See McKinsey & Company Assessment L (Leadership) in Volume II for more detail on the role of the VISN.

[100] The Bridgespan Group. (2011). *Strategies for Changing Organizational Culture*. Retrieved from http://www.bridgespan.org/Publications-and-Tools/Leadership-Effectiveness/Lead-and-Manage-Well/Strategies-for-Changing-Organizations-Culture.aspx

clear how activities performed by employees support the mission and strategic direction and how measures, directives, and requests directed by VHA Central Office align with and advance the mission.

Culture is often described simply as "how things are done around here," and changing the VHA culture will need to happen at all levels—VHACO, VISN, and the VAMC level. VHACO should consider how to integrate its efforts so that the workforce is involved and experiences a coherent set of messages, policies, and support. The VISNs should support the VAMC leaders by sharing best practices, demanding steady improvement, and encouraging innovation. VAMC leaders will need to role model the change, describe why the culture must change, reinforce desired behaviors, and provide leaders and employees alike with the coaching, training, and tools they will need to succeed. As stated in Assessment D (Access Standards), leadership at every level of the health care delivery system is essential to steward and sustain cultural and operational changes needed to reduce wait times. Leadership must be devoted to reflecting, sustaining, and enhancing patient-centered care in scheduling and access, and the results must be continually gathered, assessed, made available, and deployed to drive and reward improvement.

VHA must shift its thinking to acceptance, and in fact encouragement, of risk taking and even smart failures. A cultural and leadership emphasis on healthy risk taking was adopted across all of the high-performing health care systems we studied and should be emulated by VHA. VHA should

> "Cleveland Clinic has always had a high tolerance for renegades—the kind of people who are dissatisfied with the status quo and are always looking for better ways of doing things. Because no organization can be successful unless its people are free to learn from their mistakes, Cleveland Clinic allows ample room for failure."
>
> *Toby Cosgrove*
> *The Cleveland Clinic Way*

strike a risk-reward balance that enhances the organization's ability to reward senior leaders for the risk they assume in this increasingly politicized environment, while also making it easier to usher poor performers out of VHA. Leaders' performance plans should not only focus on compliance requirements, administrative investigation boards, root cause analyses, and peer reviews[101] but should also emphasize trends that are improving, best practices that are shared, risks taken, and accomplishments achieved. VHA must hold leaders accountable for rebuilding a culture of trust that is patient centered, streamlines processes, and expects best practices to be adopted.

Revitalize the leadership pipeline through establishment of enterprise-wide, comprehensive succession management and leadership development functions. As Assessment L (Leadership) concludes, a system as large, complex, and unique as VHA requires an enterprise-wide, highly coordinated succession management function, beyond traditional workforce planning. A comprehensive and enterprise-wide program to identify high-potential candidates, provide

---

[101] United States. Congress. Veterans Access, Choice, Accountability, and Transparency Act, 38 U.S.C. § 1701 (2014) (Pub. L. No.113–146, 128 Stat. 1754).

development in core health care administration competency functions, and connect these individuals with leadership opportunities is critical to moving VHA forward. A formal candidate identification, preparation, and placement program is required to identify and promote the next generation of leaders. Policy changes and congressional action, including expanding hiring authorities, should be sought to change or grant temporary exceptions to alleviate any constraints. The succession planning function should be coupled with development programs that strengthen VHA's leadership foundation. Current leadership development offerings should be rationalized, eliminating existing programs that do not reinforce or build on the behaviors expected of VHA leaders. Development programs should provide current and future leaders with the appropriate strategic, operational, and leadership skills to drive and implement change in this complex system and challenging environment. VHA should also attract and recruit leaders from outside the organization with deep health care management expertise who have demonstrated the behaviors and possess the competencies desired within VHA. These leaders would be expected to leverage and share their knowledge gained outside the organization while acting as catalysts for change within VHA.

Strengthen the appeal of senior leadership positions by pursuing flexibilities in hiring and compensation. The role of senior leaders within VHA should be strengthened by pursuing regulatory or legislative changes that expand or create a new federal classification for VHA Pentad leaders and other critically needed and vacant positions. These changes should enable the flexibility that exists in other federal positions (e.g., Title 38,[102] Senior Executive Service, Excepted Service[103]) to address compensation and benefits, hiring decisions, promotion process, and performance management. It should be noted that VA is pursuing a legislative remedy in its most recent federal budget request to expand Title 38 salary flexibility to non-clinical leadership positions, although at the time of this report Congress has yet to act on this request.

Establish sustained leadership continuity by extending tenure for key positions. Building sustained leadership continuity will be critical to successfully transforming culture and will give leaders the authority, accountability, ownership, and time needed to stabilize the organization, strengthen its health and performance, and shepherd change efforts. To build this continuity, VHA and Congress should consider longer terms for critical leadership positions such as the Under Secretary for Health. Extending the tenure of the Under Secretary so that it spans presidential administrations and election cycles would increase leadership stability and resilience in political headwinds. This top leadership position in one of the nation's largest health care systems could be considered akin to the Internal Revenue Service (IRS) Commissioner position. Congress passed the U.S. Internal Revenue Service Reform and Restructuring Act of 1998. That legislation allowed the IRS Commissioner a five-year term that crossed administrations and provided the opportunity to fully implement the IRS

---

[102] Title 38 is a federal classification for health care professionals and covers a range of clinical professions at VHA.

[103] There are four schedules (A, B, C, and D) of Excepted Service that fall under OPM regulations. Agencies may make Excepted Service appointments upon specific authorization by OPM.

transformation.[104] Extending the assignments of Medical Center Directors would also increase organizational stability and continuity at the facility level by ensuring that each leader is present long enough to build a rapport with the facility and his or her leadership team and see significant efforts through to completion or sustainable implementation. These extended assignments would reduce the frequency of geographic displacement, a dynamic that is becoming increasingly unattractive to many facility leaders.

8   Transformation

Taken together, the 12 assessments found numerous, critical shortfalls validating the many calls for change made by Veterans, the American public, Congress, and VHA staff and leaders.[105] These shortfalls should not be viewed as individual anomalies, but rather manifestations of the systemic findings that plague VHA:

- A disconnect in the alignment of demand, resources, and authorities that impacts mission execution
- Uneven bureaucratic business operations and processes
- Non-integrated variations in clinical and business data and tools
- Leaders are not fully empowered due to a lack of clear authority, priorities, and roles; they work in a culture of growing risk aversion and distrust.

To successfully and sustainably address these systemic findings, a system-wide transformation is required[106] based on an approach that acknowledges the interdependency among the four cornerstones as depicted in Figure 5 in Section 3.

Transformation is Hard but Possible. Transformation is not easy, nor is success guaranteed. Successful, sustained transformation requires unwavering persistence, enduring attention, committed leadership, and the sustained cooperation and commitment of those calling for change, as well as new approaches and capabilities. Across many industries, longitudinal research has found that only about 30 percent of attempted transformations succeed for the long term.[107] Employee resistance, a lack of engagement by organization leadership, scarce resources, and other organizational issues (including poor accountability and misalignment between organizational aspirations and individual and team goals and targets) are major reasons why transformational efforts fall short of their goals. Unless VHA makes major changes from its current state, it is unlikely to successfully transform.

As difficult as a major transformation is, it is still achievable. In the course of conducting the assessments and performing research for these assessments, we visited four highly regarded health care institutions that have successfully undergone transformations and emerged as high-

---

[105] A Gallup poll from June 9-10, 2014, on Americans' issue priorities found that 87 percent of Americans polled thought that improving the way in which health care services are provided to U.S. military Veterans was extremely/very important, topping the list. performing health care systems (Kaiser Permanente, Cleveland Clinic, Virginia Mason, and Geisinger). We also interviewed more than 27 health care executives and experts from industry, academia, and government. From these experiences, six themes enabling the successful transformations emerged:

- A shared sense of urgency

- Empowered leaders and new mission

- Recognition of the journey through a sustained and time-consuming process

- Patient-centric culture and value system

- Supportive and knowledgeable governance

- Transparent data-driven management system.

These themes reflect the systemic findings and recommendations provided in this report and reinforce the conclusion that a systems approach is essential to a successful VHA transformation.

VHA has also seen major transformation occur from 1994 to 1999. In 1994, care was fragmented and uncoordinated, hospital centric, specialist based, and episodic and reactionary. It was often difficult to access, with long waiting times and long distances to hospitals for some patients. The system was plagued with irregular and unpredictable quality and rapidly rising costs. Management was highly bureaucratic, centralized, and hierarchical. Organizational leadership changed frequently, and governance issues and capital investment decisions were highly politicized. Patients were unsatisfied, and staff demoralized.

After a careful, major transformational effort, there were many quantifiable examples of positive impact at the end of five years. VHA:

- Treated 24 percent more patients

- Implemented universal primary care

- Improved access with 302 new community-based outpatient clinics

- Markedly reduced waiting times

- Closed 29,000 acute-care hospital beds

- Reduced bed days of care per 1,000 patients by 68 percent

- Reduced annual hospital admissions by 350,000

- Merged 52 hospitals into 25 locally integrated multi-campus facilities

- Decreased staffing by 12 percent (25,867 FTE positions) while concomitantly increasing the number of caregivers

- Substantially decreased annual operating costs

- Decreased annual expenditures per patient by more than 25 percent in constant dollars

- Improved patient satisfaction and achieved higher aggregate patient satisfaction ratings than in the private sector (in 1998, 80 percent of patients thought that care was "definitely better" than two years before)

- Markedly improved quality of care according to standardized performance measures for a wide array of conditions.[108]

Transforming VHA to a High-Performing Health Care System: In its *Blueprint for Excellence*, VHA has captured its aspirations and goals citing the IOM's "Six Aims for High Performance Healthcare" as a framework underpinning its "clinical performance improvement and measurement for comparison with non-VA care."[109]

> *"The goal of a learning health care system is to deliver the best care every time, and to learn and improve with each care experience. This goal is attainable only through system-wide changes of the sort that have been successfully undertaken in certain activities of the manufacturing sectors. In these cases significant benefits have been realized through organization wide transformations guided by principles of systems and process engineering and the practices of structured data feedback for process improvement."[110]*

Although the goals of VHA already echo many of the system findings of our assessments, the keys to future success are effective execution and implementation. All leaders and staff must be engaged and empowered to assist overcoming challenges in the transition from strategy to execution. Most transformations take at least 12 to 18 months for initial impact, and transformations of the magnitude needed at VHA may take 5 to 10 years to fully take hold. To avoid change fatigue and loss of focus, VHA leadership must set appropriate expectations with clear milestones, but also make visible early changes to demonstrate commitment and promote front-line acceptance. To this end, as Section 4 recommends, VHA must establish a new Program Management Office staffed by individuals with the right emotional commitment and core competencies in executing organizational change. This office should answer directly to the Office of the Undersecretary for Health. This team should create the strategy and roadmap for the implementation of this transformation, with the requisite

> "Minor tweaks to the current system may incrementally improve health care in the near term, but the monopolistic VHA bureaucracy is likely to return to a standard operating model heavily influenced by the desires and concerns of the institution and its employees. Only fundamental reform will break the cycle and empower Veterans."

metrics, milestones, and timelines. This roadmap should set reasonable timelines, strive for early wins, and be willing to wait for major impact. Most importantly, VHA leadership must provide and Congress must endorse funding to enable this transformation—funding that is separate from the annual budget cycle; funding that is protected; and funding that has special rules for allocation. "A best practice is to establish an independent budget that's distributed when—and only when—the kinds of milestones"[111] that measure success have been achieved.

With this multi-dimensional systems approach to complex problems, VHA will be able to successfully tackle its most complex problems in innovative, sustainable ways. Facility challenges can be significantly mitigated by a transformative realignment throughout the capital program deploying best practices in leasing and contracting; realigning the strategy of the capital program to improve project selection, optimize the infrastructure portfolio, implement innovative care delivery models, understand demand-based needs, and explore and partner with purchased-care opportunities; and reevaluating funding requirements. Such an integrated approach would proactively position VHA for the health care delivery model of the future. Similarly, the problems of access addressed by the Choice Card should, as noted in Appendix D, integrate multiple factors—systems strategies, supply and demand alignment, reframing the type of patient encounter, the need for standards, the need for evidence-based best practices, and leadership. This holistic approach is the heart of our proposed systems solution with its four systemic cornerstones. A systems approach to solving large scale health care delivery issues has been suggested by experts at IOM, the National Academy of Engineering, and the President's Council of Advisors on Science and Technology.[112,113,114] Approaching all of the recommendations in the 12 individual assessments with a systems solution that is scalable and sustainable will provide a pathway for enduring transformation.

Conclusion: Veterans, the American public, Congress, and VHA staff and leadership all want to see and support VHA returning to a high-performing health care system. Deputy Secretary Sloan D. Gibson stated, "We know that unacceptable, systemic problems and cultural issues within our health care system prevented some Veterans from receiving timely care." We believe this Integrated Report describes a scalable and sustainable way to create the environment for enduring solutions.

But there are clear obstacles. The number of issues VHA currently faces appears overwhelming. The overlap of our individual assessment recommendations with those of past reports is troubling. The success rate of successful transformations is not encouraging.[115]

In its current state, VHA is not well positioned to succeed in such a transformation. As already discussed in the Integrated Report, three essential actions are required to realize the recommendations inherent in this transformation. VHA must:

> "Implementing systems approaches in health care, including strategies to address scheduling and access issues, requires changes not only in operational processes, but also a fundamental shift in thinking. All members of a health care organization must transition from the siloed, independent, and fragmented mentality of traditional health care culture to a culture of service excellence, an integrated approach with shared accountability in which physicians, employees, and patients treat one another with respect and as partners and patient satisfaction and employee engagement are high."
>
> *Institute of Medicine of the National Academies Assessment D (Access Standards)*

- Implement a systems approach that recognizes and embraces that the four cornerstones are interdependent and the success of any one of the four overarching recommendations hinges on the implementation of the other three. These solutions must be coordinated and implemented via a systems approach to improve VHA overall.

- Establish a transformation program management office with the authority and funding (redirected from current central and local funding mechanisms) to implement the system-wide reworking of VHA. The office should be staffed by individuals with the right emotional commitment and core competencies in executing organizational change. The office should focus on confirming and communicating the aspirational state, establishing transformation priorities, defining timelines for execution, implementing both strategic and tactical initiatives, allocating resources, and instituting appropriate metrics and processes to measure progress and success. It should replace any ongoing change initiatives and merge the relevant components of MyVA, the *Blueprint for Excellence*, and other initiatives into one coherent, focused transformational approach.

- Require evidence-based systems models to inform and implement integrated solutions that balance governance, operations, data and tools, and leadership.

VHA has the opportunity to achieve a place among the highest performing health care systems in the world. It will be the charge of Congress, the Commission on Care, and VA leadership to see that these recommendations and resulting transformation efforts are given the necessary attention and support that they—and our nation's Veterans—deserve.

Appendix A   Demographics

Scope

Assessment A examined the "current and projected demographics and unique health care needs of the patient population served by the Department." The assessment described characteristics of the current and projected population of U.S. Veterans and patients of the U.S. Department of Veterans Affairs (VA) health care system. In addition, the assessment examined the characteristics of Veterans who are most likely to rely on VA for their health care, described the unique health care needs of the patient population currently served by VA, and projected the health care needs of Veterans who might become patients in the future. The assessment also examined the potential impact of future policy changes, such as broader eligibility for VA care, and other events, such as a major conflict, on demand for VA health care services.

Findings

The population of U.S. Veterans will decrease by 19 percent over the next 10 years. The Veteran population has been has been decreasing for the past two decades, and this trend will continue. In 1990, there were 27.5 million Veterans; in 2014, there were 21.6 million. Over the next 10 years, our projections, drawing on VA and Department of Defense (DoD) data, show that the Veteran population will decline to 17.5 million, a decrease of 19 percent. Geographically, the Veteran population will shift from the Ohio River Valley and upper Midwest to the Southwest and Mountain regions and concentrate further in urban areas. Over the next 10 years we estimate that the share of female Veterans will increase from 8 to 11 percent, while the share of non-Hispanic white male Veterans will fall from 80 to 75 percent. Mean age will increase slightly as the population will have a higher proportion of both older and younger Veterans.

Veterans generally enjoy favorable socioeconomic outcomes relative to their non-Veteran counterparts. Veterans are more likely to be employed and have health insurance, and also have higher median incomes, than non-Veterans, on average. Despite the overrepresentation of Veterans in the U.S. adult homeless population, the rate of homelessness is still low among Veterans and has been declining over time.

The VA patient population will increase through 2019 and then plateau. While the Veteran population is projected to decline by 19 percent over the next 10 years, we estimate that the number of VA patients will reach its peak level in 2019 before plateauing or possibly declining in future years. The increase in the size of the patient population relative to the Veteran population is related to recent trends in eligibility, enrollment conditional on eligibility, and use of VA health care among those eligible, particularly among younger Veterans.

The number of Veterans who use VA health care is dependent on eligibility criteria, access constraints, and other factors. For example, our scenario analysis found that expanding eligibility for VA health care to currently excluded groups of Veterans could lead to over 4.8 million newly eligible Veterans, and as many as 2.1 million new VA patients, amounting to a 35.1 percent increase in the size of VA's patient population.

Lower income Veterans, those in rural areas, Veterans without other access to health insurance coverage, and Veterans with poorer self-reported health status rely more on the VA than other Veterans. Most Veterans have health care options other than VA, such as employer provided health insurance or Medicare, and use VA for only part of their overall health care needs. Our estimates of the extent to which Veterans rely on VA for health care versus other sources of care are lower than VA estimates. For example, our estimates indicate that VA patients obtain 30 percent of their prescription drugs through the VA. In contrast, VA estimates that enrollees obtain 66 percent of their prescription drugs through VA. Because the VA estimates are in part based on proprietary methods, the reasons for these differences could not be fully determined.

Veterans have higher *unadjusted* rates of many key health conditions than non-Veterans. Unadjusted results show how Veterans differ from non-Veterans at the population level. Some of these differences are related to the fact that Veterans are older and more likely to be male than non-Veteran civilians, and therefore disappear when we adjust for these factors. At the population level, the prevalence of diabetes and gastroesophageal reflux disease (GERD) disorders among Veterans is substantially higher than for non-Veterans. Veterans are more likely than non-Veterans to be diagnosed with cancer, hearing loss, and posttraumatic stress disorder (PTSD). Mental health conditions, however, are equally prevalent in the Veteran and non-Veteran populations.

Veterans have a higher *adjusted* prevalence of key health conditions than non-Veterans. Adjusted results characterize how Veterans differ from non-Veterans with similar demographic characteristics, including age, sex, and race. While Veterans continue to have a higher prevalence of many chronic conditions, most differences are smaller, relative to unadjusted estimates. For example, in the unadjusted models Veterans are almost twice as likely to have diabetes; after adjusting for demographic characteristics, the relative difference is only 13 percent. An important exception is that, after adjusting for demographics, Veterans have higher prevalence of mental health conditions than non-Veterans. Differences between Veterans and non-Veterans are particularly large for PTSD, where Veterans are 13.5 times more likely than non-Veterans to be diagnosed with the condition.

VA patients are typically less healthy than Veterans who do not use VA health care. VA patients—defined as Veterans who obtained care from a VA provider or had any payment by VA for health care services used in the past year—are in poorer health than Veterans who had not used VA health care. Partly these differences in prevalence are inevitable, because Veterans with disabilities and service-connected conditions have prioritized access to VA care relative to other Veterans. Among VA patients, the unadjusted prevalence of common chronic conditions (such as diabetes and cancer) is 51 to 96 percent higher than for Veterans who do not use VA care. Approximately 25 percent of all patients who received care paid for by VA have a mental health condition and three percent have PTSD. When combined with the otherwise rare conditions related to combat—amputation, traumatic brain injury, blindness, and severe burns—VA handles a patient mix that is distinct from what community providers typically see.

The prevalence of many common conditions is projected to increase among Veterans over the next 10 years. As the Veteran population ages, they will face higher rates of conditions such

as hypertension, diabetes, and mental health. VA patients are projected to experience relatively steeper increases in many conditions relatively to the overall Veteran population. As a result, the gap in prevalence rates between VA patients and Veterans who do not use VA health care is projected to increase over time.

In the event of a hypothetical future conflict, even moderate levels of deployment could substantially increase the size of the incoming cohort of VA patients. However, previous cohorts of Veterans, especially the Vietnam cohort, were much larger than recent cohorts, so the difference would be small relative to the entire VA patient population.

Recommendations

Prepare for a changing Veteran landscape. After increasing for decades, the VA patient population is projected to level-off or even begin to decrease after 2019, a trend that is likely to continue over an even longer time horizon. While demand for VA services during this time period will be influenced by utilization patterns, there is a possibility that demand for services will decrease for the first time in several decades once the size of the Veteran population begins to plateau after 2019. The VA has been, and continues to be, responsive to increasing demand for services, but once population growth slows, VA may be left with a larger footprint than needed in the longer-term. Increasing the use of care purchased from the civilian sector may enable VA to meet short-term increases in demand without requiring costly investment in facilities, infrastructure, and personnel that could become less needed in the future.

Anticipate potential shifts in the geographic distribution of Veterans, and align VA facilities and services to meet these needs. Given projected declines in the size of the Veteran population living in the Ohio River Valley and upper Midwest, it may be possible to consolidate relatively proximal VA facilities in those regions. At the same time, some areas of projected Veteran population growth—including Montana, Wyoming, Colorado, and much of the Southwest—are not currently well covered by VA facilities. Some regions, such as Washington D.C., Los Angeles, Dallas, and northern New Jersey, may experience growth in the Veteran population under age 35.

Improve collection of data on Veterans. Because the 2010 Census did not capture information on Veteran status, there has not been a full-scale accounting of the U.S. Veteran population since 2000. Since then, there have been surveys of representative samples of Veterans that provide useful counts and information about the Veteran population, but they are only estimates. An updated census of the Veteran population would enable a definitive count of all Veterans, while also helping to refine the sampling procedures for the yearly surveys of samples of the population.

Improve collection of data on Veteran health care utilization and reliance. To gain a clearer understanding of Veterans' health care use, VA should collect data on all sources of health care that are used by Veterans—including where care is delivered, what diagnoses are recorded and procedures performed, and who pays for the services—as well as what needs for care are unmet, and why. Creating these data would enable an analysis of the extent to which Veterans currently rely on the VA for health care, and how that reliance may change as a result of internal VA policies or external factors. It would also provide insight into where the VA succeeds

in meeting the health care needs of its patient population and what obstacles exist in delivering needed care.

Monitor use of VA health care by younger cohorts and Iraq and Afghanistan Veterans. Iraq and Afghanistan Veterans are more likely to have service-connected disabilities than other Veterans, and are automatically eligible for VA health care for five years after leaving the military. Historically, Veterans have relied less on VA health care as they age, gain access to other health insurance (e.g., through an employer), and start families. However, it is not clear the extent to which these patterns will hold for newer Veterans who have different exposures and enhanced eligibility relative to previous cohorts. Understanding how patterns for these Veterans will evolve may inform future planning.

The complete Assessment A is available in Volume II.

Appendix B   Health Care Capabilities

B.1   Scope

Access to quality health care is a central part of our nation's commitment to Veterans. However, concerns about access to VA care, including long wait times for appointments, lack of available appointments within certain clinical specialties, and problems with care transitions for patients discharged from mental health services, led to the passage of the Veterans Choice Act in 2014. Section 201 of the Veterans Choice Act includes a requirement for an independent assessment of VA health care. Assessment B provided "an independent assessment of the current and projected health care capabilities and resources of the VA, including hospital care, medical services, and other health care furnished by non-VA facilities under contract with the VA, to provide timely and accessible care to Veterans" (Veterans Choice Act, Section 201). Assessment B also explored how selected policies could affect Veterans' access to high-quality care. Volume II contains the full Assessment B report.

B.1.1   Findings

VA operates a unique health care system with broad and deep resources and capabilities. However, VA faces a number of barriers in planning for and using its resources effectively:

- **Fiscal resources:** We identified concerns about the data used for VA's budget planning, inflexibility in budgeting stemming from congressional appropriation processes, and challenges in VA's allocation processes.

- **Workforce and human resources:** VA has an extensive health care workforce, but VA capacity may not be sufficient to provide timely care to Veterans across a number of key specialties as well as primary care. VA faces shortages of physicians in some geographic areas and of certain physician specialists. These constraints are influenced by low salaries, a slow credentialing process, and infrastructure constraints. Variations in coding, inconsistently entered workload data, and incomplete physician encounter data make it difficult to measure productivity.

- **Physical infrastructure**: VA operates one of the most extensive systems of health care infrastructure in the country, but the need for additional physical space is a limiting factor in improving access, and it is sometimes difficult to update the physical space in older buildings to accommodate new technology and equipment.

- **Purchased care:** VA has many outside options for providing care to Veterans, including several programs and various types of payment or contractual arrangements, although managing these overlapping resources can be challenging.

- **Informational resources:** VA has been and continues to be an innovator and leader in IT, although there is room for improvement in some areas, including issues related to the management and planning of its IT systems. VA's electronic health record technologies suffer from aging architecture and 10 years of limited development. However, interviews suggest strong support for renewed investment in a modern, home-grown product rather than transitioning to a commercial alternative.

VA does not currently face an overall crisis in access to care; however, we found considerable variability across the dimensions of access (geographic, timely, financial, digital, and cultural). There is wide variation in access: For example, at 91 top-performing VA facilities, over 96 percent of new primary care patients receive appointments within 30 days of the preferred date. However, 14 VA facilities were far below this benchmark, with less than 84 percent of patients receiving appointments within 30 days of the preferred date. At top-performing VA facilities, more than 60 percent of Veterans report that they "always got urgent care appointments as soon as needed." At the worst-performing VA facility, this rate was closer to 20 percent. On patient surveys, Veterans are substantially less likely than private-sector patients to report getting appointments, care, and information as soon as needed.

Geographic access is another challenge for VA. Veterans are highly dispersed throughout the United States, and ensuring nearby access to needed services is difficult. Many Veterans have access to VA care by a general standard of less than 40 miles distance from any facility (measured either using a straight line or driving distance), not considering the services available. Geographic access is worse when using different types of access standards. Veterans who must rely on public transportation, for example, have much lower levels of access than other Veterans. Geographic access to specialized facilities and providers is also lower.

There is substantial variation in quality measure performance across VA facilities, indicating that Veterans in some areas are not receiving the same high-quality care that other VA facilities are able to provide. For example, there was a 21-percentage-point difference in FY 2014 performance between the lowest- and highest-performing VA facilities on the rate of eye exams in the outpatient setting for patients with diabetes.

VA uses many systems for monitoring quality. On most quality measures for outpatient care, VA outperformed other health care systems, while the performance on quality measures of inpatient care was mixed, with some better and others worse. On average, VA hospitals performed the same or significantly better than non-VA hospitals on 12 inpatient effectiveness measures, all six measures of inpatient safety, and three inpatient mortality measures, but significantly worse than non-VA hospitals on two effectiveness measures and three readmission measures..

Changes in policy can help ensure continued access to VA care. If no substantial changes are made, projections indicate that it could be more difficult in 2019 for VA to provide accessible and timely care for Veterans than it was in 2014. However, we identified several policy options to ensure that Veterans have continued access to care, including formalizing full nursing practice authority, increasing the number of VA physicians, and expanding virtual access to care.

The impact and feasibility of increasing purchased care would be highly dependent on the scope of the change. Shifting a greater share of services from VA to purchased care would require more fundamental changes to VA. We did not find evidence of a current system-wide crisis in access to VA care that would indicate that such a change is necessary, but it is possible that such a reorientation would improve both access and the quality of care. However, our analyses indicate that many Veterans without access to VA health care also face significant barriers to accessing purchased care, including distance and cultural barriers. Thus, the option

to transform VA from a provider to a purchaser of health care would not necessarily have a significant positive impact on access.

B.1.2   Recommendations

Based on the findings of Assessment B, we make several recommendations to improve access to care for Veterans:

Use a systematic, continuous performance improvement process to improve access to care. Although many VA facilities achieve very high levels of performance on key access and quality measures, there is also a great deal of variation across the system. A systematic effort is needed to identify unwarranted variation, identify and develop best practices to improve performance, and embed these practices into routine use across the VA system. Some of the best solutions may be developed locally to reflect local needs and contexts. Solutions should be designed to be responsive to Veterans' preferences, needs, and values.

Consider alternative standards of timely access to care. Timeliness standards should be reexamined. VA should examine the utility of existing alternative benchmarks, such as same-day availability or the third next available appointment. Access standards for other dimensions, such as cultural access, should also be developed and used in performance monitoring and improvement. VA should develop methods to routinely compare the timeliness of VA care with non-VA benchmarks and publish these comparisons for transparency.

Develop and implement more sensitive standards of geographic access to care. VA should compare the "one-size-fits-all" approach of driving distance to alternative standards that are more sensitive to differences between Veteran subgroups, clinical populations, geographic regions, and individual facilities. This assessment highlighted the importance of time spent driving, mode of transportation, traffic, and availability of needed services as key considerations in assessing geographic access to care.

Continue moving toward using a smaller number of quality metrics in quality measurement and improvement activities. VA maintains an extensive set of quality measures. Although use of these measures has led to improvements in care, the proliferation of measures creates burdens on staff and resources and can lead to emphasis on the measures rather than improvement in areas of care that are more likely to improve patient outcomes. VA has already moved toward reporting systems that rely on a smaller number of measures, such as Strategic Analytics for Improvement and Learning (SAIL).[116]

Take significant steps to improve access to VA care. Our projections indicate that increases in both VA resources and the productivity of resources will be necessary to meet increases in demand for health care over the next five years. The options we considered that have the highest estimated potential impact are formalizing full nursing practice authority, increasing physician hiring, and increasing the use of virtual care. These are commonly proposed options for increasing access to VA care. In addition, new models of health care delivery are emerging

---

[116] Although SAIL uses fewer measures to simplify reporting, they are composite measures which still incorporate numerous individual performance measures.

rapidly in the U.S. health care system that could improve access to care. VA should seek to be an early adopter of these new models and should build a strategy that enables and supports such innovation.

Establish VA as a leader and innovator in health care redesign. As a large integrated delivery system, VA is well-placed to innovate in comparison with many U.S. health care delivery systems. It should endeavor to maximize this opportunity, given the constraints associated with being a public entity (for example, hiring processes, salaries, budgeting). VA should also endeavor to learn from current leaders in areas where its leadership position has eroded, particularly in health IT, and seek to reestablish its leading position.

Streamline programs for providing access to purchased care and use them strategically to maximize access. Currently available programs are overlapping and confusing to Veterans and VA employees as well as non-VA providers. VA should clearly identify the objectives of purchased care access and streamline programs to meet those objectives.

Systematically study opportunities to improve access to high-quality care through use of purchased care. Some types of care may be more effectively and efficiently delivered by non-VA providers. Identification of these types of care and the impact of shifting care to non-VA providers requires an in-depth systematic analysis that was beyond the scope of this assessment.

Appendix C   Care Authorities

Scope

Assessment C examined the "authorities and mechanisms under which the Secretary may furnish hospital care, medical services, and other health care at non-Department facilities, including whether the Secretary should have the authority to furnish such care and services at such facilities through the completion of episodes of care." The Assessment C team reviewed the history of VA purchased care authorities and the programs through which VA has carried out these activities nationally and at the local level, related challenges and opportunities for VA purchased care in the future, and the ways in which varying definitions of "episodes of care" affect VA authorities and strategies for purchasing health care services.

Findings

VA has a complex set of authorities to purchase care, reflecting tension among implicit aims. Prior to the passage of the Veterans Choice Act in 2014, the Secretary of VA had longstanding authority to furnish purchased care if VHA facilities could not provide the needed services directly. Although the basic grant of authorities to the Secretary is expansive in some respects, it is not unlimited. It involves significant controls on when, how, and for whom medical care may be purchased. These controls implicitly reflect several competing aims beyond simply making outside care available, including restricting costs and maintaining a balance between VA's provider and payer functions. In sum, not only are VA's authorities for furnishing purchased care complex and scattered, but they also embody more than one aim, and those aims may operate partly in tension with each other.

The episode of care defines the "unit" of VA authorization and may help shape purchased care in practice. The authorities for purchasing care tie into "episodes" primarily through program requirements for authorization (for example, as specified under the Veterans Choice Act). However, in principle, an episode conceptually bounds a clinical problem for which a Veteran might require outside services, so it might therefore make sense to outsource care as a coherent "unit." Future refinements in defining episodes of care, and an authority framework that allows the Secretary to adopt such refinements, may be critical to supporting VA's adoption of bundled payment and value-based purchasing mechanisms in the future.

The purchased care landscape is in the midst of transformation. Numerous changes to VA's authorities and mechanisms for purchasing care are being proposed, planned, or implemented. These developments have included new administrative pilots for administering the Choice and Patient-Centered Community Care (PC3) initiatives, modifications to the eligibility criteria under Choice, revisions to VA's procurement authority for purchased care, the extension of the Choice program and reallocation of funding, and the consolidation of existing purchased care mechanisms and initiatives under a unified programmatic umbrella. With these facets of purchased care authorities and practice in flux, the full landscape of VA purchase care is not just complicated, but dynamically so. Moreover, while the proposed policy changes seek to address many different problems and issues, their sheer multiplicity suggests the drawbacks of a piecemeal approach to reform and the lack of guiding orientation and strategy for VA's purchased care enterprise as a whole.

Recommendations

VA and Congress should articulate a clear strategy governing the use of purchased care. Such a strategy should clearly explain how purchased care fits into VA's broader health care mission and establish benchmarks for success in the adoption of purchased care reforms. The strategy should provide structure for purchased care authorities and procedures, as well as flexibility to support surge needs and Veteran-centered care.

VA and Congress should address cost control explicitly and systematically to guide consistent utilization and decision-making. Existing purchased care authorities establish an indirect set of cost controls through a discretionary health benefit funded by annual appropriations. VA should address cost control in purchased care explicitly and directly through a rigorous performance evaluation of existing purchased care contracts, better and more systematic collection of data on purchased care costs, and stronger cost-control mechanisms, such as co-pays, deductibles, and utilization reviews.

VA should collect better data to accurately estimate the demand for and use of purchased care. VA lacks systematic data on various facets of purchased care, particularly at the local facility level. It needs a strong base of data and analysis to monitor purchased care costs and processes and improve outcomes for Veterans.

VA should develop a stronger program management structure for purchased care and allocate responsibility and authority to the most appropriate levels. For example, referrals should be managed locally, while large contracts (such as those under Choice and PC3) should be managed centrally. VA leadership should issue clear policy and procedural requirements while facilitating appropriate flexibility in the field at the local level.

VA should evaluate the third-party contractors administering its managed purchased care programs. As the PC3 and Choice programs are fully implemented and continue to grow, VA should establish an ongoing process for evaluating the performance of third-party administrators. It should also assess the adequacy of the provider networks, the efficiency of claims processing and other activities, and Veterans' experiences with the programs.

VA should develop clear, consistent guidance and training on its authority to purchase care. VA should create a consolidated manual on purchased care, together with associated training and messaging that explains VHA's authority to purchase care and clarifies eligibility standards and processes.

VA purchased care contracts should include requirements for data sharing, quality monitoring, and care coordination. In its contracts with outside providers and third-party administrators, VA should require routine reporting of quality measures to ensure that the quality of care Veterans receive through non-VA providers is equivalent to the quality of care offered by VA. Such contracts should also include provisions for how non-VA providers will communicate and coordinate with VA counterparts.

VA should consider adopting innovative, but tested, ways to purchase care. TRICARE and Medicare offer useful lessons in how to purchase care. VA should incorporate some of these

strategies, including outsourcing administrative functions and offering performance incentives to contractors.

VA and Congress should eliminate inconsistencies in current authorities and provide VHA with more flexibility to implement a purchased care strategy. There are several points of tension and confusion within existing authorities, including inconsistencies in standards for episodes of care, the subjective nature of some elements of 38 U.S.C. 1703 (the core statutory authority for VA purchased care), different definitions of geographic inaccessibility and wait times, and conflict between the language and intent of the rule specifying that the Choice program can be used if there is not a VA facility within 40 miles of the Veteran's residence. Congress and VA should also consider the more ambitious step of simplifying purchased care authorities and mechanisms generally, by seeking to consolidate and harmonize them. At least in principle, such a step could help reduce the complexity and ambiguity now associated with purchased care authorities and mechanisms.

VA and Congress should revise the definition of episode of care to better accommodate Veterans' needs. Under the Veterans Choice Act, VA must allow Veterans who use the Choice program to seek outside services through the completion of an episode of care, "but for a period not in excess of 60 days." The legal requirement for a fixed-term reauthorization of an episode runs contrary to evolving clinical practice and standards in the broader health care sector. A revision of this authority would improve monitoring of episodes of care and reduce the administrative burden on VA staff and Veterans.

VA and Congress should adopt a consistent strategy for setting reimbursement rates across purchased care initiatives. Such a strategy should balance cost and access considerations. In setting reimbursement rates, VA mechanisms and contracts for purchasing care should reflect the reality of local competitive market conditions.

The complete Assessment C report is available in Volume II.

Appendix D   Access Standards

Scope

Assessment D responded to language in Title II, Section 201, of the Veterans Choice Act of 2014 that mandated an independent assessment of "the appropriate system-wide access standard applicable to hospital care, medical services, and other health care furnished by and through the Department, including an identification of appropriate access standards for each individual specialty and post-care rehabilitation."

To address the requests in Assessment D, the Department of Veterans Affairs, Veterans Health Administration contracted the Institute of Medicine (IOM). The IOM formed an ad hoc Committee and instructed it to conduct a study and prepare a report directed at exploring appropriate access standards for the triage and scheduling of health care services for ambulatory and rehabilitative care settings to best match the acuity and nature of patient conditions.

Convened at the request of VA/VHA, the committee was charged with the following tasks: (1) review the literature assessing the issues, patterns, standards, challenges, and strategies for scheduling timely health care appointments; (2) characterize the variability in need profiles and the implications for the timing in scheduling protocols; (3) identify organizations with particular experience and expertise in demonstrating best practices for optimizing the timeliness of scheduling matched to patient need and avoiding unnecessary delays in delivery of needed health care; (4) consider mandates and guidance from relevant legislative processes, review wait time proposals from the VA/VHA Leading Access and Scheduling Initiative, and evaluate all evidence indicated above, along with input and comment from others in the field; (5) organize a public workshop of experts from relevant sectors to inform the committee on the evidence of best practices, their experience with acuity-specifics standards, and the issues to be considered in applying the standards in various health care settings; and (6) issue findings, conclusions, and recommendations for development, testing, and implementation of standards, and the continuous improvement of their application. Throughout its work, the committee has been guided by its view that health care must always be patient and family-centered and implemented as a goal oriented partnership.

To do so, the committee:

1. Reviewed the literature assessing the issues, patterns, standards, challenges, and strategies for scheduling timely health care appointments

2. Characterized the variability in need profiles and the implications for the timing in scheduling protocols

3. Identified organizations with particular experience and expertise in demonstrating best practices for optimizing the timeliness of scheduling matched to patient need and avoiding unnecessary delays in delivery of needed health care

4. Organized and held a public workshop of experts from relevant sectors to inform the committee on the evidence of best practices, their experience with acuity-specific

standards, and the issues to be considered in applying the standards under various circumstances

5. Issued findings, conclusions, and recommendations for development, testing, and implementation of standards, and the continuous improvement of their application.

In the course of its work, the committee considered mandates and guidance from relevant legislative processes, reviewed VA wait time proposals from the Leading Access and Scheduling Initiative, and evaluated all evidence indicated above, along with input and comment from others in the field.

Findings

The committee summarized its findings as follows:

- **Variability**: Timeliness in providing access to health care varies widely.
- **Consequences**: Delays in access to health care have multiple consequences, including negative effects on health outcomes, patient satisfaction with care, health care utilization, and organizational reputation.
- **Contributors**: Delays in access to health care have multiple causes, including mismatched supply and demand, a provider-focused approach to scheduling, outmoded workforce and care supply models, priority-based queues, care complexity, reimbursement complexity, financial barriers, and geographic barriers.
- **Systems strategies:** Although not common practice, immediate engagement for patients is achievable through queue streamlining and related systems strategies to access and scheduling.
- **Supply and demand:** Continuous assessment, monitoring, and realigning of supply and demand are basic requirements for improving health care access.
- **Reframing:** Alternatives to in-office physician visits, including the use of non-physician clinicians and technology-mediated consultations, can often meet patient needs.
- **Standards:** Standardized measures and benchmarks for timely access to health care are needed for reliable assessment and improvement of health care scheduling.
- **Evidence:** Available evidence is very limited on which to provide setting-specific guidance on care timeliness.
- **Best Practices:** Emerging best practices have improved health care access and scheduling in various locations and serve as promising bases for research, validation, and implementation.
- **Leadership:** Leadership at every level of the health care delivery system is essential to steward and sustain cultural and operational changes needed to reduce wait times.

In addition to the significant variability in wait times among care settings, among specialties, and over time, there is a lack of national standards and benchmarks for appropriate wait times. While references to timely care appear regularly in legislative proposals, a prevailing definition of timeliness has not yet emerged. While national standards for access and wait-times do not presently exist, the committee did also identify examples of organization-specific benchmarks

---

within various health care settings. For example, some organizations set internal benchmarks of same-or next-day engagement for new and returning patients in primary care (Southcentral Foundation's Alaska Native Medical Center) or first time appointments of newly diagnosed cancer patients (Dana- Farber/Brigham and Women's Cancer Center in Boston); internal benchmarks guide door to provider times within emergency departments (Virginia Mason Hospital), wait times for specialty new visits (Cincinnati Children's Hospital), and primary care backup practices for urgent services (Tufts Health Plan Network Health). The Joint Commission has also developed standards pertaining to emergency department boarding times and hospital discharge risk assessments. Organization-specific benchmarks, such as these, serve as promising reference points for future research and validation.

Recommendations

The committee issued four recommendations for health care delivery systems leadership, leading to: 1) front-line scheduling practices anchored in the basic access principles, 2) governance commitment to leadership on basic access principles, 3) patient and family participation in designing and leading change, and 4) continuous assessment and adjustment at every care site.

Specifically, the committee recommended that:

1. The front-line scheduling practices of primary, specialty, hospital, and post-acute care appointments should be anchored in basic access principles, including: supply matched to projected demand, immediate engagement, patient preference, care tailored to need, surge contingencies, and continuous assessment.

2. The leadership and governing bodies at each level of the health care delivery sites should demonstrate commitment to implementing the basic access principles through visible and sustained direction, workflow and workforce adjustment, the continuous monitoring and reframing of supply and demand, the effective use of technology throughout care delivery, and the conduct of pilot improvement efforts.

3. Decisions involving designing and leading access assessment and reform should be informed by the participation of patients and their families. The potential ways that patients could provide their expertise through informal or formal channels (e.g., patient and family advisory councils, surveys, and focus groups) include contributing input on their expectations, experiences, and preferences for scheduling practices and wait times; helping representatives of health systems explore alternative access strategies; contributing to the design of pilot improvement efforts; helping to shape communication strategies; and interfacing with governance and leadership.

4. Care delivery sites should continuously assess and adjust the match between the demand for services and the organizational tools, personnel, and overall capacity available to meet the demand, including the use of alternate supply options such as alternate clinicians, telemedicine consults, patient portals, and web-based information services and protocols.

The complete Assessment D report is available in Volume II.

This page intentionally left blank.

Appendix E   Workflow – Scheduling

E.1   Scope

Health systems across the United States have struggled with ensuring optimal patient access to the services they provide, and VHA is no exception. Although the Veterans Health Administration (VHA) has faced public concerns about access to outpatient care for several decades, many factors that influence access have been only partially analyzed to date at VHA and were called out in the Choice Act as areas for independent assessment. The Choice Act tasked Assessment E with assessing "the workflow process at each medical facility of the Department for scheduling appointments for Veterans to receive care, medical services, or other health care from the Department." The assessment was also asked to address several supplemental areas related to provider scheduling templates, scheduler training, the use of call centers and the appointment scheduling system. All of these factors—as well as others explored in Choice Act assessments such as overall health care capabilities (Assessment B) and clinical staffing (Assessment G)—are critical to ensuring that our Veterans receive improved access to care. Volume II contains the full Assessment E report.

E.1.1   Findings

In this assessment, we have reviewed VHA performance in the scheduling workflow areas against best practices from both within VHA and across the private sector. The major finding of this assessment is that VHA is not fully leveraging provider resources, scheduling best practices, or scale to deliver the best possible scheduling experience and access for Veterans. These shortcomings have a negative impact on both patient access to outpatient appointments (in terms of total number of appointments available and the matching of patients to those available appointments) and the patient experience of scheduling an appointment with VHA. It is likely that, with improved data visibility, more streamlined processes and performance management, VHA could expand the supply of appointments even with its existing provider base, as well as improve overall utilization of appointment supply and patient experience.

More specifically, we observed the following challenges that reduce the overall effectiveness of VHA scheduling today:

- **System limitations prevent accurate visibility into the supply of available appointments, inhibiting VHA's ability to understand the gap between total appointment supply and demand and to effectively manage current performance and plan for the future**. Due to system design limitations, some providers operate across multiple, potentially overlapping, booking templates or "clinic profiles" for any given day or session. As a result, these profiles, when aggregated, provide an inaccurate picture of total available appointment supply and make it challenging to easily understand whether appointment supply matches the quantity VHA should expect given the number of providers. The issue of overlapping profiles not only affects centralized calculations of overall and provider-level appointment supply, but also makes it challenging to calculate provider utilization rate, which is an essential metric for

managing access to care. These limitations mean VHA cannot determine how much patient demand its current provider capacity can meet in a timely manner.

- **Imbalance between supply and demand has led to policies that add responsibilities for schedulers and administrators.** Because VHA has a persistent backlog of patient demand, VHA created additional policies that do not exist in the private sector, such as the capture of patient desired date and the use of the Electronic Wait List (EWL). These policies for measuring wait times and managing waitlists have resulted in a significant number of additional activities required within the scheduler's day-to-day workflow. Further, the implementation of these policies is left largely to frontline interpretation, which may also result in inconsistent experience for patients across clinics or facilities. For example, use of the EWL varies across clinics; some clinics use it solely to measure backlog while others use it to highlight patients who may be willing to take an appointment that becomes available at the last minute (Choice Act site visits, interviews 2015). Veterans may then experience variation in when they are removed from the waitlist depending on how their clinic has implemented EWL.

- **Clinics do not consistently employ standard industry practices related to schedule setup and other scheduling processes.** VHA clinics are inconsistent in their use of industry and VHA best practices in scheduling, resulting in a fewer appointment slots available than may be possible within existing provider capacity and a significant number of booked appointments not being completed as originally scheduled. On schedule setup, examples of these practices in common use in industry and within certain services (such as Primary Care) within VHA include using standard appointment lengths within a sub-specialty and determining appointment mix (for example, number of new patient slots) based on patient demand (Institute for Healthcare Improvement (IHI), "Reduce Scheduling Complexity," n.d.; Primary Care Clinic Profile Standardization Guide, 2014). Similarly, inconsistent scheduling practices, such as the ways in which appointment reminders are used, exist across facilities and clinics. For example, a patient could expect a reminder from a clinic and not receive it (and potentially not go to the appointment as a result). Ultimately, the variability in these practices may result in reduced appointment availability and utilization as well as inconsistent patient experience.

- **Facility-level differences in performance management and accountability limit system-wide improvements in access.** VHA facilities lack consistent organizational structures for managing scheduling or access and, in many cases, lack dedicated resources to manage performance and outcomes for these activities. Given structural differences, formal monitoring of schedules is not a clearly defined duty for any staff members at the facility level, which hinders cross-system sharing of best practices, policy dissemination, and process standardization. In addition, this lack of consistency in organizational structure and accountabilities limits VHA performance management of facilities, as no one individual is specifically accountable and data analysis is

---

cumbersome.[117] The Veterans Choice Act (Section 303) identified this lack of accountability and aims to assign management of access responsibilities to a particular role within each clinic and to provide tools and processes to help perform this duty ("Veterans Access, Choice, and Accountability Act of 2014," 2014). VHA plans to fulfill this mandate without any new facility hires; instead, the organization will designate current FTEs as owners of these responsibilities at the clinic and facility levels (Access and Clinic Administration Program [ACAP], interviews, 2015).

- **VHA-specific processes paired with a scheduling system that does not simplify processes leads to a greater reported need for scheduler training**. In response to a survey, 90 percent of schedulers noted the need for additional training in at least one area (for example, wait times and wait list policies) to become proficient at executing their basic responsibilities (Assessment E VHA Employee Survey, 2015). This perceived need for enhanced training may be due to systems and processes that do not simplify scheduler responsibilities, a common focus among private sector health system executives we interviewed. For instance, scheduling systems of private sector health systems have more user-friendly interfaces, fewer unique programs, and more automated processes (Private sector health system, interviews, 2015). As a result of greater complexity, VHA schedulers must receive additional training (on wait times and wait list policies, for example) to become proficient at executing basic VHA scheduler responsibilities.

- **Scheduling call centers are not maximizing their performance due to their small scale and disparate service offerings.** VHA call centers are smaller than industry standard (median size of 12 agents within VHA compared to 28 agents in private sector health systems and 110 agents across other industries) (Assessment E national data call, 2015; Belfiore et al., 2015). The scheduling call centers that do exist provide different services and support different specialties depending on the facility. Due to efficiencies in managing call demand that can lead to service improvement for patients, other provider systems have, in some cases, moved to pooling call volumes in more central locations. Larger scale call centers can also have lower per-unit costs and put less stress on space-constrained facilities than facility- or clinic-based operations. Further, larger call centers may be able to offer more coaching, training and career options to schedulers.

E.1.2   Recommendations

VHA has received significant feedback on ways to improve its scheduling and access performance. In fact, since 1999, more than 35 reports by the Government Accountability Office, VA itself, VA Office of the Inspector General (OIG), and independent contractors have commented on possible approaches for VHA to improve scheduling and access. Despite the number of reviews, there has been little articulation of the fundamental need for VHA to solve its ability to manage provider appointment slot supply until the Institute of Medicine's February

---

[117] For example, at present, there is no easy or automated way to consistently and accurately monitor provider schedules.

The views, opinions, and/or findings contained in this report are those of the assessment team and should not be construed as an official government position, policy, or decision.

2015 "Innovation and Best Practices in Health Care Scheduling" white paper, which recommended that VHA get "back to the basics" to understand provider supply vis-a-vis patient demand and ultimately design schedules that optimize the two. With the access crisis and subsequent Choice Act in 2014, VA/VHA have accelerated several efforts to address issues raised in past reports, including funding provider hiring and non-VA care, initiating the procurement of a commercial off-the-shelf (COTS) scheduling system referred to as the Medical Appointment Scheduling System (MASS), and designing a clinic manager training program to better manage the scheduling process. However, to drive overall improvement to scheduling and address the specific challenges described above, we recommend that VA and VHA successfully complete in-flight initiatives and consider additional actions, which would be most effective if executed in an integrated manner. These actions include the following:

- **Address system limitations to provide visibility into aggregate appointment supply, alternative measures of wait times, and provider-level performance data.** VHA providers can operate across multiple and sometimes overlapping clinic schedules (also known as "profiles"),[118] which can result in double-counting of appointment slots when aggregated. VHA has a current initiative to clean-up overlapping schedules and unused clinic profiles that should result in a more accurate view of each clinic's appointment slot supply. Although this is an important first step, the effort may not eliminate all overlap in schedules and will not by itself allow understanding of appointment supply and utilization. One consolidated schedule for each provider would allow VHA to capture total appointment supply and measure the industry-standard wait time metric. With VA OI&T's current procurement of a new scheduling system (discussed in detail in section 7, Scheduling System), VHA may be on the path to addressing system limitations. Of course, when updating or acquiring a system to support scheduling, it is important to understand the business case relative to modifying the existing system or locally sourcing solutions at the facility / regional level.

- **Codify proven scheduling practices and empower clinics to improve appointment utilization and deliver a consistent patient experience.** Several pockets of scheduling best practice exist within VHA, such as the predictive missed opportunity model. However, many of the best practice VHA tools and processes are not widely disseminated nor utilized. The VHA ACAP Office reported that it is beginning to codify system-wide knowledge of scheduling best practices, but there is also an opportunity to ensure that these practices are consistently utilized in the field (ACAP, interviews, 2015). This will require addressing the lack of clinic management resourcing, addressing scheduler vacancies and ensuring that providers have an understanding of why certain practices (for example, overbooking) may be necessary to provide access.

- **Streamline scheduling policy implementation with supporting tools and implementation guidance; where possible, utilize technology to support.** The current Scheduling Directive policy is designed to aid VHA facilities in managing in an environment of excess demand relative to the appointment supply it is offering. This has

---

[118] Described in Provider Availability Section 5 of this report

resulted in policy steps, such as wait time capture and wait list management being added to the scheduling process, which can result in inconsistent patient experience due to discrepancies in policy interpretation and implementation in the field. For instance, to adhere to the policy regarding the Electronic Wait List, the scheduler will place a patient scheduled outside of 90 days on a wait list, an additional step in the scheduling process (Choice Act site visits, interviews, 2015). Further, while the EWL prioritizes Veterans to be scheduled based on policy, schedulers can find it challenging to use the list in conjunction with other policies (e.g., how many times the patient should be called before moving to the next patient on the list). In contrast, an ideal system would automatically place relevant patients on the EWL, provide a manager with a comprehensive dashboard for monitoring the waitlist demand, and prioritize which patients should get the first available appointments based on additional parameters. As a result, these changes would improve schedulers' efficiency and improve consistency of policy implementation.

- **Improve scheduler training by sharing local best practices and increasing experiential and on-the-job training, while also minimizing the need for training by simplifying policy implementation and improving system functionality.** Currently VHA's need for scheduler training is exacerbated by its scheduling software, policies (like EWL), and clinic- and provider-specific scheduling rules. Improvements to the scheduling systems, streamlining policy implementation, and minimizing unnecessary clinic-specific rules would reduce demands for schedulers' training and create more consistent patient scheduling experience. To optimize its training program, VHA should also leverage local best practices to create an improved and standardized curriculum for training and minimize duplication of materials development at the facility-level. In addition, training should be delivered using more experiential training methods to increase its effectiveness and information retention by schedulers.

- **Design scheduling call centers that can provide expanded services for Veterans relative to current state.** Currently, VHA scheduling call centers are managed locally at the facility level. As a result, most are small (median size of 12 schedulers, based on facilities that responded to our data call) and each call center varies in regards to the responsibilities and specialties for which it is responsible (Assessment E national data call, 2015). Decentralized call centers are difficult to centrally monitor and manage with regards to patient experience. Through the new myVA effort, the organization is examining how it interacts with Veterans across various channels (such as, web, call centers, mail). This includes a VA-wide Call Center Task Force that may ultimately address scheduling; however, the scope does not yet appear to be clearly defined. VA has an opportunity to evaluate its current call center use for scheduling and develop an approach based on existing VHA call centers in other areas (like Health Resource Centers) and leading private sector scheduling call centers. VHA can then evaluate which responsibilities and specialties should be handled at larger scheduling call centers. Additionally, VHA should analyze the appropriate degree of centralization (for example, regional or virtual call center) and the call center locations.

- **Ensure that the clinic manager training program and subsequent implementation are appropriately scoped and resourced to drive access and clinic management.** Different roles, accountabilities and levels of expertise exist across facilities for managing access and scheduling, which affects how access and scheduling is managed and prioritized at different facilities. Via the Choice Act, VHA was directed to develop a clinic management training program to address these gaps within the system. While many important scheduling functions are reported to be addressed in the training curriculum as it is currently envisioned, resourcing and accountability for these activities will be equally important in ensuring that VHA is able to fully utilize its provider capacity and the appointment supply made available to Veterans. Further, tools need to be developed and distributed to ensure that these new clinic managers are successful.

Despite many of its broader organizational and operational challenges, VHA can leverage multiple positive aspects of its current scheduling and access management practices in the future. For instance, VHA's scheduling policy has created the mechanism to identify potential supply-demand imbalances by tracking patients waiting for care at the clinic level. Similarly, VHA's efforts to encourage patient appointment adherence through a multi-pronged patient reminder approach, coordination of transportation and efforts to coordinate multiple services, where possible, demonstrate a commitment to supporting Veterans receiving care. Additionally, locally developed scheduling innovations demonstrate the potential for new scheduling tools and practices within the organization. For example, several VA Medical Centers (VAMCs) have developed home-grown "best practice" tools, including the predictive missed opportunity model, aggregated views of provider availability, and facility-centralized patient reminder systems across multiple modalities. In addition, VHA can build on its early efforts to modernize its patient-facing scheduling capabilities, such as online self-scheduling. This foundation suggests that VHA can draw on experience and assets within the organization, as well as on external best practices, to improve its scheduling processes.

In summary, if VA / VHA were to continue to build on existing assets, execute on its in-flight initiatives and supplement them by executing on the recommendations above, it may be able to offer a more consistent experience across clinics and facilities, expand appointment supply with existing provider resources and ensure better utilization of its supply. The impact of this for Veterans could come in the form of both improved experience and improved access.

Appendix F   Workflow – Clinical

F.1   Scope

Assessment F (Inpatient Clinical Workflow), Section 201 of the Veterans Access, Choice, and Accountability Act of 2014 ("The Choice Act") mandates an assessment of the "organization, workflow processes, and tools used by the Department to support clinical staffing, access to care, effective length-of-stay management and care transitions, positive patient experience, accurate documentation, and subsequent coding of inpatient services." Pursuant to this language, Assessment F focused on the organization, workflow processes, and tools (i.e., structural components and approaches) in place within acute care hospitals to facilitate the five identified sub-assessments as both individual components as well as part of the interdependent continuum of inpatient care. Comparison of current VHA practices to accepted best practices (drawn from literature and professional associations), as well as standard practices (drawn from public and private sector benchmarks) provided insight into alternative approaches and recommendations. While selected performance outcomes were used to prioritize areas of focus, a complete analysis of clinical, performance, operational, or other outcomes associated with the employed approaches was not in scope for this assessment. Volume II contains the full Assessment F report.

F.1.1   Findings

Our assessment identified both cross-cutting strengths and opportunities for improvement as well as findings and recommendations specific to each of the five sub-assessment areas reviewed.

F.1.1.1   CROSS-CUTTING FINDINGS

We observed three common themes supported by findings across sub-assessment areas.

- **Ineffective data collection and management drives a lack of transparency into many key aspects of clinical operations, hindering VHA's ability to effectively manage inpatient care**. Despite having a well-regarded EMR system and the capability of tracking extensive clinical data, poor data collection and management of operational metrics was a consistent theme heard during site visits. Furthermore, it was clearly evident from our central and local requests for specific information. Data that is standard in private sector hospitals was frequently inaccessible in a timely manner or not tracked in a usable format by VHA. For example, VHA FTE and payroll data includes information by clinical occupation but not by department, which prevented planned analysis of the appropriateness of staffing, since needed staffing levels vary considerably by department (e.g., the ICU requires more concentrated nursing attention than med/surg floors; see Volume II, Assessment F, Section 5 for more detail). We observed data integrity and availability issues significantly affecting VHA's visibility into clinical operations in four of our five sub-assessment areas and believe that this likely affects VHA's ability to manage operations at the local and national levels.

- **VHA resources (e.g., staff, beds) do not always match Veterans' care needs.** The practical allocation and prioritization of resources across the VHA system may not be consistently aligned to meeting the broader health needs of the Veteran patient population. Mis-match of resources to patient care needs manifests itself in three ways: hiring that does not consistently match staffing needs; allocation of staff to tours ("shift") that do not consistently match Veteran demand; and limited access to appropriate outpatient and post-/sub- acute care options. An example of the impact limited outpatient and post-acute care options has on Veterans can be seen in the abundance of inpatient admissions and continued stays that do not meet acute care admissions or continued stay criteria. National Utilization Management (NUMI) data[119] indicates that 23 percent of inpatient admissions (see Volume II, Assessment F, Section 6 for more detail) and 34 percent of inpatient stays overall do not meet admission and continued stay criteria (see Volume II, Assessment F, Section 7 for more detail). Many are admitted to, or remained in the hospital, due to challenges in accessing the appropriate level or type of care (e.g., primary care, detoxification center, post-acute rehabilitation). The disconnect between resources and demand has clear implications on VHA's ability to effectively and efficiently provide the care needed to improve the health and well-being of Veterans.

- **While best practices exist in selected pockets, communication and support for implementation at scale appears to be a challenge**. Our site visits revealed several clear best practices in place at various VAMCs; however, adoption of these practices was isolated even within the facility. Case studies of particularly strong programs are included in all sub-assessments. Despite successfully adopting best practices in some units, however, facilities appeared to struggle to implement programs house-wide. Moreover, information-sharing between VAMCs appears to be limited and ad hoc. As one Assistant Director of Patient Care Services described, "I'm shameless about stealing what works at other places, the problem is, I don't know what other places are doing. We need a way to connect, to learn from each other"[120]. This sentiment was echoed by many staff across all of the facilities we visited.

SUB-ASSESSMENT FINDINGS

In addition to the broad cross-cutting findings, a review of each sub-assessment identified specific strengths and opportunities for improvement within their areas of focus.

- **Clinical staffing:** Siloed resource management (e.g., limited coordination across service lines on FTE requests), poor data management, and limited guidance on staffing methodology result in staffing practices that are seldom evidence-based, outside of a few best practice areas (such as nursing). This prevents VHA from knowing whether staffing

---

[119] NUMI (National Utilization Management Integration): supports national utilization management agenda by providing a common tool for tracking performance on utilization management metrics across facilities

[120] Facility interview

---

allocations are appropriate. Furthermore lengthy hiring timelines and inconsistent alignment of staff to patient care needs have downstream implications.

- **Access:** Best practices exist at disparate facilities however, their lack of systemic adoption combined with an inaccurate understanding of patient demand and available capacity and inconsistent admission and bed assignment practices hinder inpatient access.

- **Length-of-stay and care transitions:** National efforts to improve length-of-stay have been hampered by challenges meeting discharge needs of patients requiring specialized post-acute care (e.g., homeless, psychiatric diagnoses), inefficiencies in care delivery practices (e.g., limited availability of weekend consults), and inconsistent approaches to discharge planning often delay care transitions and discharge beyond private sector benchmarks.

- **Patient experience:** Best practice innovations are evident at the national and local levels, but challenges with patient satisfaction data transparency and national implementation support limit system-wide adoption.

- **Documentation and coding:** Limited understanding by providers and coders of the link between coding and resource allocation, coupled with limited performance management, likely contribute to sub-optimal documentation practices yielding lost revenues and misaligned resources. Despite these challenges, coding performance is a relative strength and comparable with industry standards.

F.1.2   Recommendations

Across sub-assessments, our recommendations also fall under three major themes:

- **Improve clinical management through establishing clear operational metrics, and streamlining data collection focused on clinical priorities, monitoring, and performance management**. Appropriately defining standards for high performance and having accurate information on how departments and facilities measure against defined targets is the foundation of managing operations. Site visits, data analysis, and comparison against best and standard practices suggest that VHA lacks such visibility into clinical operations, significantly reducing its ability to address challenges and innovate (see Volume II, Assessment F, Section 3.1). We believe that improving transparency is critical to ensuring effective, timely, and efficient delivery of care to Veterans, across many of our sub-assessment areas. In part, transparency could be improved through enhanced data management, meaning both better data integrity and sharper focus on a targeted set of key metrics needed to assess performance. Equally important, VHA should ensure that facilities have clear operational guidelines on how to set and track appropriate performance goals (e.g., by providing comprehensive staffing methodologies for service lines with no national guidance).

- **Realign resourcing (for example, staff, facilities) to allow VHA to serve patients at the appropriate level of care (such as, increase Veteran access to sub-acute and post-acute care to reduce clinically inappropriate admissions and prolongation of acute inpatient stays)**. We observed many instances in which VHA resources were not appropriately matched to patient demand. As described in Volume II, Assessment F, Section 3.2, there is a disconnect between resources and demand in delayed hiring of staff needed to

The views, opinions, and/or findings contained in this report are those of the assessment team and should not be construed as an official government position, policy, or decision.

F-3

support patient care, mis-allocation of staff to tours (i.e., shifts), and limited outpatient and post-acute care options needed to ensure treatment at the appropriate level of care. In order to provide high quality care that promotes the health and well-being of Veterans in a cost efficient manner, VHA should ensure that resourcing allows the system to serve patients at the appropriate level of care. Broadly, we see three categories of changes that could help effect this recommendation: improve hiring, allocate staff to match patient demand (e.g., align that staffing on weekend, holiday, and evening hours is sufficient to meet patient need), and increase access to outpatient and post-acute care options.

- **Scale existing best practices and support further innovation at the local and national levels.** A consistent theme during our site visits and interviews was that the opportunity to build off of existing strengths within the system was encumbered by limited sharing of best practices across VAMCs (see Volume II, Assessment F, Section 3.3). In instances where best practices have been developed nationally, challenges appear to exist due to unclear guidance on implementation, occasional flaws in the design of programs, and lack of VAMC adoption. In instances where best practices have been developed locally, scaling seems to be inhibited by limited infrastructure for information-sharing and lack of resources. To address both sets of challenges and fully leverage and build off of institutional strengths, we suggest improving practices through a combination of targeted national guidance (e.g., streamline Veteran-centered care initiatives and mandates) and nationally-supported local best practice-sharing and innovation (e.g., build infrastructure to promote cross-facility sharing of patient flow best practices).

Several recommendations will require national coordination, while others could be implemented in the near-term at the facility level. We have provided additional tactical steps, titled near-term actions, for associated recommendations at the sub-assessment level and encourage facilities to review these and take action quickly at the local level where appropriate. Additionally, several pre-conditions for implementation (see Section II, Assessment F, Section 4.2.1) have been identified for prioritization by Congress and VACO to support a successful and sustainable system-wide transformation.

Implementing solutions to long-standing challenges will require collaboration among Congress and the Executive Branch, VA leadership (VACO, VISN, and VAMC) and staff, as well as the unions and external stakeholders. We see this assessment as an opportunity for improvement, to be achieved by all stakeholders through a combination of local, regional, and national action. Addressing these challenges will require sustained commitment as a part of an integrated transformation effort for the system as a whole.

Appendix G   Staffing/Productivity

Scope

Assessment G (Staffing/Productivity) examined "the staffing level at each medical facility of the Department and the productivity of each health care provider at such medical facility, compared with health care industry performance metrics, which may include an assessment of the case load and number of patients treated by each health care provider, time spent by health providers on matters other than caseload, including time spent at an affiliate, conducting research, training or supervising other health care professionals of the department."

Findings

The Assessment G team had several key findings and observations pertaining to the core assessment objectives: staffing, productivity, and time allocation.

The Assessment G team analyzed VHA provider staffing levels and compared them to the private sector (using physician per population ratio industry comparisons) and identified some of the challenges VHA faces in ensuring it has sufficient providers to meet demand. With respect to provider staffing levels, the Assessment G team found that:

- **VHA specialties with the highest provider full time equivalent (FTE) levels include medicine specialties, mental health, and primary care, consistent with VHA's care model and the needs of the Veteran population**. Social Workers also represent a significant portion of provider FTEs. VHA does not systematically track fee-basis provider productivity, and does not capture FTE level information for fee-basis care providers.

- **VHA physician staffing levels per population are, in most specialties, lower than industry ratios**. These ratios are not sufficient to establish whether VHA is staffed to meet demand. One factor to consider is that even industry physician supply is not sufficient to meet demand in many specialties. Another factor to consider is that VHA uses Advanced Practice Providers (APPs) extensively, but APPs are not included in industry ratios.

The Assessment G team also assessed the productivity of VHA providers in comparison to providers in the private sector. With respect to provider productivity, the Assessment G team found that:

- **VHA measures the performance of its primary care providers (PCPs) using panel size.** VHA calculates a modeled panel size for providers based on a variety of factors at each facility. The model was developed based on research into the appropriate panel size for the unique needs of Veterans.

- **In accordance with policy, VHA facilities establish a maximum panel size for each primary care provider which is often lower than the modeled panel size.** The maximum figure takes into account specialized panel needs (for example, a geriatric population) and other factors deemed appropriate by the facility.

- **The actual panel size of VHA primary care providers is lower than internal and external benchmarks.** The actual panel size for VHA general practice physicians is 13 percent

below the VHA modeled panel size, 12 percent below the external benchmark, and 5 percent below the facility maximum.

- **When compared to the private sector using wRVUs, there is a productivity gap in VHA specialty care**. When encounters (visits) are used as a measure, the gap shrinks and VHA specialty care compares more favorably to the private sector. VHA mental health providers are more productive than academic medical center (American Medical Group Management Association [AMGMA]) benchmarks, as measured by both wRVUs and encounters.

- **Overall, VHA specialty care providers are producing fewer wRVUs than private sector benchmarks; however, VHA specialty care providers at the highest complexity facilities are more productive than their peers**. Further, the most productive VHA providers (those at the 75th percentile of VHA providers) are often more productive than the private sector.

- **Productivity and access are important measures in population based health models like VHA that focus on patient outcomes, rather than volume**. VHA's Office of Productivity, Efficiency, and Staffing (OPES) reports on productivity and access offer tools for use by medical facilities. With some improvements to expedite adoption and regular use by medical centers, these tools could become key resources in optimizing productivity and maximizing access to care.

- **VHA dentists see fewer patients on average than private sector benchmarks, but serve a population with special needs**. The dentistry patient population of VHA generally has a compensable service-connected dental disability, is older, has more complex injuries, and may present for dental care following years of dental neglect.

The Assessment G team identified several barriers which limit provider productivity and may explain the differences between VHA provider productivity and that of the private sector, especially in specialty care. These include:

- A shortage of examination rooms and poor configuration of space

- Insufficient clinical and administrative support staff ratios

- Providers may not fully document and accurately code all of their clinical workload, which may impact the accuracy of wRVU productivity measurement

We noted the insufficient clinical and administrative support staff ratios as a key barrier to optimizing productivity and studied this more closely. More specifically, we found that:

- While there has been widespread implementation of the Patient Aligned Care Team (PACT) model in primary care clinics and the National Nurse Staffing Methodology in many areas of inpatient care, **there are no current VHA standards for staffing levels and/or mix in specialty clinics**, with the exception of eye clinics. Furthermore, VHA OPES has developed state of the art tools for managing staffing and productivity, but these tools will require improvements for leaders to more effectively leverage them in resource decisions.

- **Organizational siloes and separate reporting lines exist for physicians, nurses and medical service administrators at a majority of VA Medical Centers** (VAMCs). As a result, service chiefs do not have control over the resourcing and performance of their clinical support staff (nurses) or clerical and administrative support staff.

- **Many facilities do not have a centralized staffing office or nurse float pool to address daily staff variances or absences.**

With respect to how providers spend their time, the Assessment G Team observed that:

- **VHA physicians spend a comparable proportion of total time devoted to clinical activities as private sector physicians.** There is some potential difference in the definition of direct patient care used by the private sector, specifically with respect to training, teaching and research, but we believe this represents only a small proportion of a provider's direct patient care time.

- **Across all VHA providers, less than two percent of time is devoted to research.** Since provider time spent devoted to clinical care activities is comparable to the private sector, it does not appear that research activities reduce providers' time spent treating patients. Despite the overall low proportion of time spent on research, the accomplishments of VHA's research program, and contributions to advancing care for Veterans, are numerous.

Recommendations

Taking the above findings into consideration, the Assessment G Team offers five cross-cutting recommendations:

VHA should improve staffing models and performance measurement. VHA should conduct an evaluation of the design and implementation of current VHA staffing models to determine the extent to which they are sufficient to meet the goals of VHA's population health focused model and ensure all eligible Veterans have access to high quality, timely care. VHA should conduct a program review of the implementation of the PACT staffing model in primary care to identify the causes of the gaps between actual, facility maximum, modeled and external benchmarks, the impacts of these performance gaps on access to quality care, the appropriateness of current guidelines and performance standards, and determine areas for improvement. VHA should develop and implement staffing models for outpatient specialty care services and improve existing performance measurement systems to realize the benefits of specialty care staffing models. VHA should refine and implement the National Nurse Staffing Methodology across inpatient services and improve the performance measurement system to realize the benefits of the methodology. We further recommend that VHA mandate all VAMCs adopt and report nursing quality metrics to a national database to compare VHA to other external health organizations.

To improve staffing and productivity measurement and better determine the capacity of VHA specialty clinics, this assessment recommends that VHA gather data and assess the productivity of fee-based providers, as well as conduct a work measurement study (or confirm existing workload data) to determine the volume and distribution of workload annually to better match staffing requirements to demand. For future reporting, OPES should complete the development

of the APP productivity cube, to include completion of business rules that would allow APPs to be mapped to a specialty designation and included in OPES specialty group practice and facility productivity reports to accurately reflect care teams' overall effort and present a combined provider (doctor of medicine [MD] and APP) productivity view.

VAMCs should create the role of clinic manager and drive more coordination and integration among providers and support staff. We identify recommendations for increasing the level of teamwork and accountability among all outpatient clinic staff, especially in specialty care services. This might be achieved by creating multidisciplinary management teams for specialty clinics that include a physician leader, nurse leader, and business administrator. Alternatively, specialty clinics might establish a single or dual reporting line and operating a model for providers and their clinical and non-clinical support staff, so that all of the members of the specialty clinic team have more accountability to each other and the Service Chief of the specialty.

VA Medical Centers should implement strategies for improving management of daily staff variances, and include a replacement factor for all specialties, including PACT. With respect to managing staff absences, we make recommendations for improving the management of daily staffing variances by implementing several strategies that include intermittent float pools of support staff and the inclusion of a replacement factor across all staffing methodologies/models, to include PACT.

VA Medical Centers should implement local best practices that mitigate space shortages within specialty clinics. We identify recommendations to help VA medical facilities mitigate space shortages within specialty clinics. These include strategies such as: standardized schedule templates, expanded clinic hours, increased use of non-face-to-face encounters for follow-up consults by specialty care, and system redesign initiatives to improve patient flow within clinics.

VHA should improve the accuracy of workload capture. We recommend that VHA conduct an audit of health record documentation and current procedural terminology (CPT®) coding accuracy and reliability to validate physician productivity measurement and that if the results support it, evaluate the ability of commercially available computer assisted coding (CAC) applications to assist providers with coding. The creation of the role of clinic manager for Specialty Care clinics should also be used to improve clinic management and coding practices.

Appendix H   Health Information Technology

Scope

Assessment H responded to language in Title II, Section 201, of the Veterans Choice Act of 2014 that mandated an independent assessment of "the information technology strategies of the Department with respect to furnishing and managing health care, including an identification of any weaknesses and opportunities with respect to the technology used by the Department, especially those strategies with respect to clinical documentation of episodes of hospital care, medical services, and other health care, including any clinical images and associated textual reports, furnished by the Department in Department or non-Department facilities." The recognition that Veteran health and satisfaction constitute important measures of information technology (IT) effectiveness guided the assessment team's investigations and the resulting recommendations.

To gain comprehensive insight into Department of Veterans Affairs (VA) health IT and the strategies that guide its implementation, the Assessment H team conducted 185 interviews in the course of site visits to Veterans Integrated Service Networks (VISNs), VA Medical Centers (VAMCs), and Community Based Outpatient Clinics (CBOCs), as well as VA's Office of Information and Technology (OI&T). The team also reviewed plans, reports, audits, and protocols procured from OI&T and VHA, as well as external reports and journal articles relevant to health IT and complex system development. Further, the team compared its observations and findings against lessons learned and best practices identified by executives, administrators, clinicians, and IT professionals at high-performing private health systems. Because IT touches nearly every aspect of operations at VHA, the data gathered by Assessment H generally supports the qualitative evidence related to IT collected by the other assessments.

Findings

Several decades ago VA led the development of electronic health record (EHR) technology with its Veterans Health Information Systems and Technology Architecture (VistA) system and Computerized Patient Record System (CPRS) systems. Most VHA clinicians have a high opinion of the clinical applications and databases enabled by VistA and CPRS, as well as VA's newer technologies such as telehealth and mobile applications (apps). Several Assessment H interviewees attributed the success of the early VistA and CPRS development efforts to the close working relationship between VistA/CPRS developers and clinicians. This collaboration seems to have disappeared with the centralization of IT in 2006, resulting in uncoordinated execution of health IT strategy and limited development of new and improved capabilities for VistA/CPRS. During the past decade, VistA and CPRS development has been confined to point solutions and minor enhancements.

Clinical users have become increasingly frustrated by the lack of any clear advances during the past decade. Numerous VHA clinicians have experience with commercial EHR systems and want the same level of features, modern clinical capabilities, integration, and mobility they see emerging in the commercial marketplace.

VHA and OI&T do not collaborate effectively with respect to the planning and execution of IT strategies for managing and furnishing health care. Although the goals of OI&T and VHA do not conflict at the strategic planning level, the organizations often do not agree on priorities for executing the strategic plans.

During the past decade, VA's ability to deliver new capabilities for its VistA system to meet changing Veteran health care needs has stalled. As a result, VA/VHA health care systems are in danger of becoming obsolete. The VistA/CPRS systems are based on a tightly integrated, monolithic architecture and design with numerous and diverse functional components and associated interdependencies. These characteristics impose significant barriers to modernizing these systems. In addition, the high cost of infrastructure operation and maintenance (85 percent of the total IT budget) reduces funding available for new development efforts. Maintenance and data sharing are further complicated because most VAMCs have customized their local versions of VistA, leading to approximately 130 different instances of VistA across the country.

Overly demanding processes for system development, as defined by OI&T's Project Management Accountability System (PMAS), impede cost-effective delivery of new health IT capabilities and limit VA's ability to measure the value of IT investments. The PMAS process is schedule driven and risk averse, leading many project managers to limit the amount of functionality in each release, thereby increasing the total time for any useful capability to be released.

The lack of standard clinical documentation has made it harder to develop effective clinical decision support systems and hinders EHR information exchange among VAMCs, between VA and non-VA facilities (including those of the Department of Defense [DoD]), and between VA and the individual Veteran. The lack of data standards presents challenges to using comparable data for analysis and disparities among the 130 tailored local instances of VistA complicating information sharing, data aggregation, and analytics. The outdated technology underlying VistA weakens VHA's ability to leverage powerful new technologies for extracting information from free-form text, processing genomic data and images, and extracting and analyzing data from personal health monitoring devices.

While VA has successfully developed and deployed telehealth capabilities and mobile apps, it does not effectively assist end users of these technologies and it does not match the pace of the commercial marketplace. VA's support for telehealth users (patients and clinicians) is weak, understaffed, and poorly integrated with IT systems. In addition, barriers associated with providing VISN-to-VISN telehealth make optimizing the caseload across VISNs more difficult, creating unnecessarily long waits for care in certain regions. VA has the opportunity to apply mobile technology at a low price point, but until VA improves its IT development process to emphasize delivery instead of process, it cannot match the pace of the commercial marketplace with respect to delivery and improvement of mobile apps. These limitations prevent VA from realizing the strategic value of mobile technologies as an enabler of both Veteran access and Veteran satisfaction.

Recommendations

VA/VHA must resolve IT challenges comprehensively, targeting solutions to the entire system rather than seeking to solve isolated problems. To their credit, many leaders within OI&T and VHA, as well as administrators, health information management and IT professionals, and users at the facility level, recognize the need to address these issues. This report describes a future vision for VA/VHA as a high-performing health care system and a continuously learning health system that implements enterprise IT service management best practices.

At the strategic level, VA and VHA need to transform IT strategy, planning, and execution in a systematic manner with dedicated executive-level leadership. Specifically:

The VA chief information officer (CIO) should select a CIO for VHA to manage and advocate for VHA's IT needs and assist in transforming the VA IT strategy to a model based on enterprise IT service model standards and best practices. This involves taking the following actions, explained in more detail in this report:

- Establish mutually acceptable IT service level agreements and optimize them for effectiveness.
- Refine the planning and budgeting process to ensure that business needs are effectively identified, prioritized, funded, and used to drive health IT investments.
- Develop a governance policy to ensure the strategic plans are executed well and in a timely manner.
- Establish product (capability)-focused teams to ensure delivery of needed capabilities to users.
- Refine VA's agile development process from a document-and-schedule focus to a delivery focus.

The VHA CIO, in partnership with the VA CIO, should oversee a comprehensive cost-versus-benefit analysis between a commercial off-the-shelf (COTS) EHR and continued in-house custom development of the VistA EHR currently in use. The analysis should take into account all the complexities of the VistA/CPRS architecture and infrastructure and known issues with performance, scalability, extensibility, interoperability, and security. It should also address full life-cycle costs, including development time (based on recent delivery trends), availability of development resources, maintenance and licensing costs, and infrastructure costs. VIS

The VA and VHA CIOs should conduct site visits and review the successful IT practices implemented at high-performing health care systems (including VISN4), to inform their strategies for effective approaches and potential contributions that IT can provide to improve the treatment of Veterans today.

The VA CIO and VHA CIO should report to Congress at the end of fiscal year 2016:

- Evidence that the VHA CIO serves as an effective advocate for the IT needs for health care delivery. This should include, but not be limited, to a description of the requirements for an effective health care management system to provide a basis for comparing VistA and COTS EHRs.

- Actions taken and evidence that OI&T acts as a service provider and delivers IT capabilities and IT services that improve health care delivery to Veterans. Evidence should include results of clinician and Veteran surveys confirming the quality of and satisfaction with the newly delivered capabilities and services.

- Results of the cost-versus-benefit analysis between a COTS EHR and continued in-house custom development of the VistA EHR.

VA should implement a broad process, inclusive of clinicians, to pursue requirements that support clinical documentation best practices and improved functionality and usability while considering the positive aspects of existing systems. Although providers can continue to leverage the free text capability available in the current EHR, it must be augmented with discrete, structured data capture using industry standard definitions to increase the interoperability with other systems inside and outside of VHA. This is especially critical due to the increased use of non-VA care.

VHA should accelerate efforts to establish semantic definitions for data elements through the use of standard nomenclatures, terminologies, and code sets. By doing so, VA can ensure consistency and integration across multiple systems, leverage follow-on IT products, and facilitate analytics for clinical decision making.

VA/VHA should assess the effectiveness of analytical products in driving health and business outcomes. They should identify and recommend improvements needed in the information systems that serve as the sources of the data to improve the reporting capabilities. VA/VHA should track actions taken as a result of the analytical products and quantify how effective those actions were in improving health and business outcomes.

To reduce the number of Veterans who abandon telehealth, VA should offer technical support to Veterans, should make testing a connection between Veterans and providers easier for all parties, and should better integrate telehealth technologies across VA medical facilities and VISNs. Assisting Veterans with use of this technology should improve the Veteran experience and reduce health care costs. VA should also address the challenges that complicate telehealth appointments between VISNs.

VA should explicitly identify mobile applications as a strategic enabler to increase Veteran access and satisfaction and help VHA transition to a data-driven health system. Mobile technology could effectively leverage patient-generated data to augment the data captured in the EHR to feed the learning health system.

Appendix I   Business Processes

Scope

Assessment I reviewed the "business processes of the Veterans Health Administration, including processes relating to furnishing non-Department health care, insurance identification, third-party revenue collection, and vendor reimbursement, including an identification of mechanisms as follows:

- To avoid the payment of penalties to vendors.

- To increase the collection of amounts owed to the Department for hospital care, medical services, or other health care provided by the Department for which reimbursement from a third party is authorized and to ensure that such amounts collected are accurate.

- To increase the collection of any other amounts owed to the Department with respect to hospital care, medical services, and other health care and to ensure that such amounts collected are accurate.

- To increase the accuracy and timeliness of Department payments to vendors and providers."

I.1   Summary of Findings

VHA Revenue—VHA is Not Optimizing Revenue Due to Ineffective Veteran Insurance Identification, Clinical Documentation and Coding, and Cultural Barriers.

Ineffective Veteran-facing (front-end) VAMC processes for insurance identification, and clinical documentation, and outpatient coding issues result in CPAC staff members having to address issues "after-the-fact." The issues correspond to $581 million in denials from insurance companies in 2014.

For first-party (Veteran) co-payments, VAMC staff members are not collecting the co-payments at the point-of-service and CPACs must collect the co-payments weeks to months after the date of service. Further, based on feedback from VAMC leadership, Veterans do not always understand the need to provide insurance information and VHA staff can be reluctant to ask for it.

Revenue processes span across VAMCs and CPACs; however, only the CPACs are accountable for revenue collection and the associated performance outcomes. VAMC commitment is required to monitor and correct issues early in the process to reduce collections delays and denials.

Non-VA Care Payments—VHA Does Not Have Adequate Infrastructure and Streamlined Processes to Pay Non-VA Care Claims Timely and Accurately.

VHA's complex and disparate processes for paying Non-VA Care claims are confusing to Non-VA providers and VHA staff, resulting in inconsistencies in authorization and payment practices. VHA's mechanisms to pay Non-VA claims timely and avoid delinquent payments, particularly at

select VISNs. However, inadequate data analytics indicate the issues could be more widespread. VHA mechanisms to avoid delinquent payments to external providers are inadequate putting VHA at risk for significant interest penalties.[121]

Inadequate claims submission guidance discourages widespread use of electronic claims submission. VHA receives only a small percentage of non-VA claims electronically, which increases workload, manual processing, and the likelihood for payment errors. Low staff retention and a 20 percent vacancy rate further exacerbate delays and errors in claims payments.

VHA established Patient Centered Community Care (PC3) to expand Non-VA care access by entering into national contracts with Healthnet and TriWest to provide Veteran health care on a fee for service basis. Feedback from VA employees interviewed indicate that PC3 is experiencing challenges due to gaps in the non-VA provider network.

Information Technology—Lack of Automation and Integration Prevent VHA from Optimizing Performance in both Collections and Payments.

VHA will not be able to make necessary improvements in their billing and collection processes without modern, automated technology. Antiquated systems used to support the revenue collection processes for third-party reimbursements and first-party (Veteran) co-payments do not provide needed functionality. These systems require significant manual intervention and processing that creates an environment prone to human error and delayed claims payments from insurers.

VHA software tools and functions do not interoperate across clinical and revenue management systems and their limited interoperability with other internal and external systems inhibits VHA's ability to bill and collect revenue accurately and rapidly.

Few Non-VA providers submit their claims to VHA electronically, relying instead on paper claims, which reduces payment timeliness and accuracy. In addition, staff members process claims manually compared to private-sector benchmarks of 79 percent automation.

Oversight and Metrics—VHA Lacks Certain Performance Reporting to Provide Effective Oversight and Proactive Process Improvements for Collections and Payments.

VHA lacks standard national reporting of key performance metrics for timely insurance identification and verification across VHA, inhibiting visibility into VAMC insurance capture performance of VAMCs. In addition, VHA cannot establish effective productivity standards and monitor Non-VA Care staff performance because processes are inconsistent across VAMCs and VISNs. Current decision support capabilities are not sufficient to provide oversight and management of Non-VA Care claims processing and payment. Proactive and retrospective processes are in place to find inaccurate payments, but these practices are highly manual.

---

[121] There is an ongoing VA Office of General Counsel review of the universe of payments to which the Prompt Payment Act applies.

I.2　Summary of Recommendations

Recommendation 1—VHA: Develop a long-term comprehensive plan for provision of and payment for non-VA health care services.

The expansion of Non-VA Care over the last decade has resulted in a combination of programs that lack sufficient infrastructure to successfully perform the business functions today or meet the demands of the future. The demand for Non-VA Care will be determined, in large part, by the decisions made regarding VHA care and, in turn, by VHA's capacity to meet demand for services. For example, decisions about VHA facilities and workforce will affect demand for Non-VA Care, as will changes in the demographics and clinical needs of Veterans. VHA should adjust the plan as necessary depending on ongoing studies regarding VHA's capacity.

Recommendation 2—VHA: Establish a formal governance model that allows CBO and VISN leadership to converge, aligning interests and accountability.

The growth of both VHA and Non-VA Care requires an increased focus on business processes to sustain care for an increasing Veteran population. An organizational structure that balances central management with local autonomy is vital to VHA. VHA must align accountability and interests at the leadership level of CBO and the VISNs. Under the current alignment, CBO is dependent upon the VAMCs and VISNs to execute core business functions. With CBO and VISNs reporting separately to the VHA Office of the Under Secretary, VAMC priorities do not always align with CBO's. Placing both organizations under a single governance structure will promote convergence of interests, accountability, cooperation, and coordination.

Recommendation 3—VHA: Standardize policies and procedures for execution of Non-VA Care, particularly the Choice Act, and communicate those policies and procedures to Veterans, VHA staff, VHA providers, and Non-VA providers.

Examination of the claims processing protocols and operations revealed opportunities to standardize the manner in which VHA implements Non-VA Care and the Veterans Choice Act across the organization. Standardization will enable VHA to communicate processes and benefits effectively to both patients and Non-VA providers.

Recommendation 4—VHA: Employ industry standard automated solutions to bill claims for VHA medical care (revenue) and pay claims for Non-VA Care (payment) to increase collections, to improve payment timeliness and accuracy.

The growth of both VHA and Non-VA Care over the last decade has produced a combination of programs that lack sufficient technology to support the execution of routine business functions. In large part, these deficiencies result in a high degree of manual intervention required to bill and pay claims. The focus on automation should expand to include integration with front-end processes such as scheduling, insurance identification and verification, medical records, and coding.

Recommendation 5—VHA: Consider and further evaluate aligning the Patient Intake and Health Information Management Service (to include Coding) functions under CBO.

An emerging practice in private-sector health care is to align all components of the revenue cycle under the Chief Financial Officer (CFO) linking job responsibilities to financial performance. VHA's revenue cycle activities currently owned by the VAMC/VISN are Scheduling, Pre-Registration, Registration and Coding—all primary functions for identifying and verifying insurance, and ensuring accurate and timely first- and third-party collections. The private sector has recognized that aligning these functions under a single organization improves accountability and revenue cycle performance. Our findings indicate that the separation between business process and organizational structure within the VHA revenue cycle processes has resulted in a lack of coordination and consistency in these functional areas. Given the size and complexity of VHA compared to the private sector, any realignment needs to be carefully considered. Added to this, the VHA CBO recently completed a very large organizational consolidation of Non-VA Care employees and adding significantly more responsibility to the CBO at this time may be difficult for the CBO to absorb in the near-term.

Recommendation 6—VHA: Align performance measures to those used by industry, giving VHA leadership meaningful comparisons of performance to the private sector.

VHA should continue its progress toward implementation and management reporting of common industry performance measures. Once these practices are in place, VHA should identify performance standards that balance meeting VHA requirements with achievable, incremental performance improvements. This approach would immediately allow VHA to leverage common industry measures and benchmarks to conduct analysis, make informed decisions, and help to bring VHA performance into congruence with private-sector benchmarks.

Recommendation 7—VHA: Simplify the rules, policies, and regulations governing revenue, Non-VA Care, eligibility, priority groups, and service connections, educate all stakeholders, and institute effective change management.

Simplifying the rules, policies, and regulations will allow VHA to execute business processes uniformly, and to communicate clearly with all stakeholders.

Recommendation 8—VHA: Identify, share and institutionalize best practices across the agency.

There are numerous examples of business practices in VHA (as described in section 4 of this report) that produce results that significantly exceed VHA averages. VHA should develop a recurring process to examine these peer organizations' "positive deviants" and determine where successful practices apply to VHA business processes. Doing so will enable VHA to not only standardize, but also improve upon current best practices.

Appendix J   Supplies

J.1   Scope

Assessment J examined the "purchasing, distribution, and use of pharmaceuticals, medical and surgical supplies, medical devices, and health care related services by the Department." In line with the language of the legislation, pharmaceuticals, medical and surgical supplies (hereafter referred to as clinical supplies), and medical devices are considered within the scope of this assessment. In addition, services directly related to the purchasing, distribution, and use of these products are also considered, such as third party distributors and inventory management services. As the strengths and opportunities related to pharmaceuticals are quite distinct from clinical supplies and medical devices, the assessment is structured in two parts: (1) pharmaceuticals and related services, and (2) clinical supplies, medical devices and related services. Findings and recommendations are outlined below and described in more detail in the full report found in Appendix J.

J.2   Findings

J.2.1   FINDINGS RELATED TO PHARMACEUTICALS AND RELATED SERVICES

VA pays low prices for pharmaceuticals overall but several factors limit its ability to consistently access the lowest price available. Through mandated price concessions and national contracting, VA has relatively low pricing overall for pharmaceuticals. However, pharmaceuticals are not always bought at the lowest price available for a number of reasons, including inconsistencies between Federal Acquisition Regulations (FAR) and VA Acquisition Regulations (VAAR), contract lapses, national drug shortages, and requirements to buy from countries that are compliant with the Trade Agreements Act (TAA).

VA's distribution of pharmaceuticals to Veterans and to facilities is efficient and effective: VA's pharmaceutical prime vendor (PPV) is a distributor that sources pharmaceuticals and delivers them to VA facilities. The PPV model ensures efficient delivery of pharmaceuticals to facilities and Consolidated Mail Order Pharmacies (CMOPs) and supports a just-in-time inventory management approach. It received unanimous support from the pharmacists, pharmacy managers, and CMOP leaders interviewed during this assessment.

Supporting distribution directly to Veterans, VA's seven CMOPs deliver 80 percent of outpatient prescriptions directly to Veterans' homes, and they do so efficiently and cost effectively at $1.53 per prescription[122]. The CMOP program also achieved the highest overall customer satisfaction scores of any U.S. mail order pharmacy in a recent J.D. Power customer survey.[123]

VA has developed effective mechanisms to drive appropriate utilization such as its formulary, clinical use guidelines, and involvement of clinical pharmacists: Physicians and pharmacists

---

[122] VHA Pharmacy Benefits Management. CMOP Overview for the Secretary. Filename: CMOP Info 4-1-15.pptx

[123] J.D. Power (2014) U.S. Pharmacy Study

believe the VA formulary helps guide good clinical decisions, and they express strong buy-in to the formulary process. Veterans have access to medications based on clinical need regardless of their formulary status. Standardized processes enable off-formulary prescribing, including electronic submission of clinical justification by physicians and review by clinical pharmacists. Around 80 percent of off-formulary requests are approved and five percent of outpatient prescriptions are for non-formulary drugs.[124]

High generic drug use supports delivery of high quality, FDA-approved medications to Veterans while ensuring efficient use of taxpayers' dollars. While VA does not measure generic use as industry does, VA purchases 97 percent of its drugs (by volume) as a generic when a generic exists[125] – similar to health care leader Kaiser Permanente which claims 99 percent generic prescription dispensing when a generic exists[126]. However, there are pockets of opportunity to use a higher share of generics within certain drug classes in some geographies.

VA has implemented policies and processes to improve patient transitions from the Department of Defense (DoD) to VA but challenges remain: Prior reports have highlighted challenges to Veterans' transitions directly from DoD to VA care, particularly related to medication continuity. VA has taken steps to improve this process in recent years, including the release and implementation of a January 2015 directive. However, three key challenges remain in the transition: timely access to primary care before existing prescriptions run out, limited mobility of health information between DoD and VA, and some differences in the DoD and VA formularies (see Appendix J, Section 3.2.4 for more detail).

VA has successfully implemented programs to reduce utilization of high-risk medications and early results are promising: For example, VA's opioid reduction program has cut the share of patients prescribed opiates by almost three percentage points since 2012. However, there are opportunities to improve the current measurement approach by taking into account the type, strength, and dosage frequency of opioids dispensed.

J.2.2 FINDINGS RELATED TO CLINICAL SUPPLIES, MEDICAL DEVICES, AND RELATED SERVICES

The organizational structure of the VA's supply chain enterprise is unduly complex and duplicative: VA and VHA both contain organizations that play a role in the management of VA's medical supply chain. There are several areas of overlap between VA and VHA overall, between national and regional contracting organizations, and between the four VA-level contracting organizations. Senior leaders in VA's and VHA's supply chain organizations who were interviewed unanimously said that the current organizational structure is too complex and should be simplified to improve collaboration, ownership and accountability.

VA's current IT systems, data systems, and analytical capabilities related to finance, inventory management, and purchasing are major impediments to effective supply chain management:

---

[124] VHA Pharmacy Benefits Management. 2014 Outpatient dispensing data

[125] VHA Pharmacy Benefits Management. 2014 PPV purchase data

[126] Kaiser Permanente, http://businesshealth.kaiserpermanente.org/manage-costs/pharmacy/ accessed June 2015

VA's IT and data systems in these areas are antiquated, not integrated, and do not meet the needs of a modern health system. Health, procurement, finance, and contracting systems do not communicate needed information seamlessly, requiring manual manipulations leading to data inaccuracies and tracking problems. VA has at least 130 separate instances of its clinical, procurement, and inventory management systems, each with its own product nomenclature and numbering for items. As entries are mainly free text, data from each instance can be quite different and cross-site comparisons or regional/national roll-ups are almost impossible. This situation is a major impediment to effective management of VA's medical supply chain.

The performance of VA's contracting organization does not meet customers' expectations, so frontline staff have developed workarounds: Users are not satisfied with the communication, responsiveness, and time it takes for contracting requests. At one facility, data showed it took on average 21-39 days from the date of initial submission to receive the first response from contracting[127] requesting, for example, additional information or paperwork. Conversely, individuals in contracting reported VAMC requests submitted to them were often incomplete or unclear, and facilities were poor at forecasting demand for items, leading to unpredictable peaks in demand for contracting services that exceeded their capacity.

Two interrelated workarounds avoid delays from contracting: (1) staff buy the majority of their clinical supplies and devices on VA-issued purchase cards to enable greater autonomy to choose products and buy through preferred suppliers; and, (2) staff mainly place orders below the $3,000 micro purchase threshold. As a result, approximately 98 percent of VA's purchases of clinical supplies are made on purchase cards[128], which can limit VA's ability to ensure compliance with regulations because purchase card holders are responsible for identifying appropriately priced goods and contracted vendors, and VA's current systems do not support these tasks with integrated catalogs and controls. This likely leads to higher prices paid for goods. Purchase card processes are also inefficient when compared with modern alternatives, such as electronic order transmission and funds transfer.

VA has not taken full advantage of its scale or potential for product standardization to achieve optimal pricing and efficiency: Unit prices showed significant variation in the price paid for identical items. In addition, at least 27 percent of clinical supply purchases were made at open market prices[129]. Unlike pharmaceutical purchasing, VA's supply purchasing systems are not integrated with contract or pricing catalogs. This results in limited ability to monitor and drive compliance with contract usage. In fact, over 60 percent of all clinical supply items have no contract number listed.[128]

VA has achieved limited product standardization leading to a fragmented supplier network and a high number of items managed by the logistics organization. Despite some efforts, there is no routine mechanism to identify products for which central contracts should be established.

---

[127] VAMC IFCAP/eCMS communications log

[128] VHA Procurement and Logistics Office. FY2014 IFCAP purchase data for five VISNs

[129] VHA Procurement and Logistics Office. Four months FY2015 system-wide clinical supply orders with IMF numbers

Inventory management process, practices, and systems are neither integrated nor optimized: VA has contracts with six Medical/Surgical Prime Vendors (MSPVs) – distributors like the PPV that provide services supporting purchasing, distribution, and use of clinical supplies. To date, VA takes limited advantage of services offered such as electronic ordering platforms or lean delivery models, resulting in suboptimal utilization of the MSPV program. There is also no robust feedback loop linking inventory to product utilization, contracting, and ordering, which leads to fluctuating demand for contracting services that can overwhelm its capacity.

VA struggles to attract, hire, and retain high caliber supply chain talent: Interviewees estimated 20-30 percent of positions were currently unfilled. As an example, VA had 563 open positions for medical supply aides and technicians[130] – 20 percent of all those positions or almost four vacancies per facility. Supply chain leaders perceive three factors contribute to recruitment and retention challenges: recent position downgrades, long lead times to fill positions, and lack of a clear career path. Moreover, competition for supply chain talent in health care is also high and organizations are paying more to attract and retain the highest performers.

There are pockets of good performance and innovation across VA's supply chain that could be replicated across VA: The Denver Acquisition and Logistics Center (DALC) is a bright spot within VA's supply chain organization in its acquisition and distribution of select devices such as hearing aids to Veterans. It has developed an integrated operating model that brings together clinicians, contracting, finance, logistics, and program management to create a holistic view of what is best for Veterans. Another VA strength is the autonomy VAMCs and VISNs have to test and pilot new processes, management approaches, and technologies. Several innovations were observed during this assessment that could be scaled across VA to improve service to Veterans.

J.3   Recommendations

J.3.1   RECOMMENDATIONS RELATED TO PHARMACEUTICALS AND RELATED SERVICES

Establish mechanisms to ensure VA secures a reliable supply of pharmaceuticals and accesses the lowest possible pricing more consistently. The largest hurdle to accessing favorable pricing more consistently, is its management of suppliers and at-risk supplies. To that end, VA should improve lifecycle management of contracts to prevent lapses, and identify drugs at highest risk of shortages and price spikes, and develop specific strategies to limit impact. VAAR and FAR conflicts are also likely to cause confusion among VA contracting officers. VA should consider updating the VAAR, including options to ensure fair competitive prices are obtained when only a single supplier is on the Federal Supply Schedule.

Continue driving efficiency through VA's CMOP network. VA should drive more volume to CMOPs, increase automation of packing and shipping to improve throughput and quality, and optimize the network's footprint to improve utilization of fixed assets and reduce costs.

---

[130] VHA Office of Workforce Services May 2015 staffing update

Develop strategies to improve the transition of patients from DoD to VA care. Access to primary care during a transition and better interoperability between DoD and VA are key improvements for ensuring continuity of care and clinical management. Improvements for access can be found in Assessment B and Assessment E, while recommendations for improving IT strategy can be found in Assessment H. VA should also explore opportunities to align or integrate formularies taking into account clinical evidence and economic impact. As differences are likely to remain because of different Departmental strategies, VA should develop drug-class-specific guidance for medication changes related to transitions and explore opportunities to improve communication with Veterans about their medications during transitions.

Build sophisticated approaches to drive appropriate utilization of pharmaceuticals. VA has the opportunity to be a health care leader with respect to pharmaceutical use. To that end it should incorporate evidence-based prescribing guidelines into clinical protocols and pathways, building upon recommendations in Assessment F. Enabling these developments will require investment in IT and analytic capabilities to support outcomes-based data analysis. Ensuring compliance and changing physician behaviors should be driven with appropriate data interpretation and utilization through peer review, and by building utilization rules into prescribing systems to reduce inappropriate use.

J.3.2 RECOMMENDATIONS RELATED TO CLINICAL SUPPLIES, MEDICAL DEVICES, AND RELATED SERVICES

Transform and consolidate VA's entire supply chain organization. VA should rationalize the organizational structure by consolidating VA and VHA entities into one integrated supply chain organization. Guiding principles should include a single accountable leader for policy and end-to-end effectiveness, governance including all supply chain elements, clear expectations for supporting functions and users, and alignment of personnel by product categories. In making changes, VA should ensure the pharmaceutical supply chain is not negatively impacted; rather its practices are incorporated to improve clinical supply and medical device management.

Performance management focused on Veteran outcomes should be supported by service level agreements between supply chain functions and its end users, based both on end users' expectations and what is feasible within the constraints in which VA operates. Enhancing VA's performance management system will require a level of standardized data capture and reporting that is not possible with VA's current data systems. Therefore, system upgrades and/or replacements should be considered as per the recommendation below.

Improve key enablers required to support the organizational transformation, including IT systems, data standardization, and talent management. VA should update or replace supply chain IT systems to make them fit for purpose. Any decisions made should be in line with VA's overarching IT strategy and in full consideration of the interoperability and interdependencies between supply chain, financial, and clinical systems.

VA's lack of data standardization is a major impediment to effective monitoring and management of its supply chain. It should be a high priority to standardize supply chain data and overlay user-friendly interfaces that enable robust and timely decision-making across the enterprise. As a first step, VA should evaluate near-term options to standardize critical data

---

The views, opinions, and/or findings contained in this report are those of the assessment team and should not be construed as an official government position, policy, or decision.

elements to enable some level of cross-comparability. This should include establishing a central item master file with standardized nomenclature and numbering of VA's commonly used items.

The future of VA's supply chain rests on the talent that can drive these changes, therefore professionalizing the supply chain workforce by creating clear opportunities for training and advancement within the organization should be a priority.

Streamline, standardize, and integrate key supply chain management processes. VA should expedite product standardization in key categories by prioritization. The approach should build upon learnings from VA's pharmacy committee structure, with its integrated cascade of testing, review, feedback, and decision-making related to selection and use of pharmaceuticals.

VA should expedite its process mapping initiative and also look holistically at acquisition policies and regulations to streamline contracting and purchasing processes. Electronic and automated purchasing processes should be improved and encouraged. Additionally, VA should build upon its ability and willingness to experiment by establishing an approach to more systematically capture, codify, prioritize, and if appropriate, scale innovations across VA.

The complete Assessment J report is available in Volume II.

Appendix K   Facilities

Scope

Assessment K examined "the process of the Department for carrying out construction and maintenance projects at medical facilities of the Department and the medical facility leasing program of the Department." Specifically, the team was required to (i) review the processes for identifying and designing proposals for leases and capital projects, (ii) assess the process for determining the necessity and size of a lease or capital project, (iii) assess the processes and project management of the design, construction, leasing, and activation of medical facilities, and (iv) assess the medical facility-leasing program of the department. The Assessment K team also considered two additional areas that are critical to addressing VHA's facility needs, facility management and the long term capital funding needs of VHA.

Findings

We have found that VHA is expected to face accelerating and likely unfunded capital requirements driven by maintenance to aging infrastructure, projected workload needs to serve the Veteran population, and inefficient capital management. Moreover, we observed that VA performance in capital management, design and construction, leasing, and facilities management is on par with public sector performance in most cases, yet well below private sector performance, particularly in the cost to deliver major construction projects. Consistently deploying world class practices in capital management has the potential to improve performance significantly and address some of the capital constraints VA faces, but would require a further overhaul of VA's capital program and supporting organization. However, even if VA is able to meet the significant challenge of achieving best practice performance in capital management, VA would still likely experience a significant capital funding gap that will require strategic changes in operations and additional funding to close the gap.

The capital requirement for VHA to maintain facilities and meet projected growth needs over the next decade is two to three times higher than anticipated funding levels, and the gap between capital need and resources could continue to widen.

VA has identified more than $51 billion in total capital needs over the next 10 years through its capital planning methodology.[131] These requests cover current ten-year projections; however, new projects may be added as needs change and could change the total capital requirement. Provided that average funding levels remain consistent over the next 10 years, the $51 billion

---

[131] The $51 billion capital requirement combines $46 billion in projects submitted through the Strategic Capital Investment Plan (SCIP) and $5 billion in anticipated outstanding funding needs for on-going major projects projected in the FY2016 VA Budget Submission. While our team did not independently verify the cost estimates for the 8,038 capital requests that make up the $46 billion requests through SCIP, we did review the process by which these requests are identified and developed. See Section 3.1 and Appendix B.3 for additional detail.

capital requirement would significantly exceed the anticipated funding level of $16–26 billion.[132]

Multiple factors drive the scale of the capital need. VHA facilities are older buildings, with significant repair needs, and some are poorly suited to emerging models of care. The average VHA building is 50 years old, five times older than the average building age for not-for-profit hospital systems in the United States.[133] While many facilities have been extensively renovated, the renovations themselves have aged, and the condition of buildings shows this strain. Independent assessments of infrastructure and facilities through the VHA Facilities Condition Assessment (FCA) found that VHA facilities average a "C minus" score, meaning that much of the total facilities portfolio is nearing the end of its useful life.[134] More than 70 percent of VHA facilities correction costs result from infrastructure and facilities that are D rated, meaning that they are at the end of their useful life.

Current facilities, whether they have been maintained adequately or not, often do not match current models of care. The overwhelming majority of VHA hospitals were designed when care was focused more heavily around inpatient hospital treatments. Over the past eight years, Veteran inpatient bed days of care have declined nearly ten percent while outpatient clinic workload has increased more than 40 percent.[135] Space for outpatient care is typically housed in converted inpatient spaces or VHA's growing number of clinics. As a result, VHA's capital needs fall into a broad range of categories, including ensuring adequate facility condition, providing sufficient and appropriate space for Veteran care, and upgrading infrastructure. As facilities age further and care continues to shift to the outpatient setting, the size of the capital need could continue to grow.

Shortfalls in overall accountability, role clarity, personal ownership, internal communication, and proactive problem solving approaches limit the ability of VA and VHA to deliver the correct projects consistently on time and on budget. Facilities functions are dispersed through VA, resulting in a lack of accountability for facilities outcomes, a mismatch between planning efforts and funding decisions, and the separation of project execution and facilities management. Additionally, internal VA directives, federal procurement requirements, and stakeholder involvement impact VHA's ability to deliver and operate medical facilities at the level of private sector benchmarks.

---

[132] Over the last four years, VA's capital funding budget has ranged from $1.6 billion to $2.6 billion each year, averaging $2 billion.

[133] The age of VHA facilities is calculated by taking the year built recorded in the Capital Asset Inventory and weighting it by the gross square footage of each property. 2013 analysis of 139 not-for-profit hospital systems in US, encompassing 1,362 hospitals (Soule & Keller, 2013). See Section 5.2.1.4 for additional detail.

[134] FCA assessments are conducted by independent evaluators at each facility every three years. More than 180,000 individual items are scored across VHA facilities, using a scale of A (like new) to F (critical condition) scale. Average score was calculated using the aggregated reports in VA's Capital Asset Database, accessed March 2015.

[135] Workload reported by VAMCs in the 2015 VSSC Trip Packs, aggregated by VISN.

Capital is not being consistently allocated to projects that address the greatest areas of Veteran need in the most cost effective and timely manner. Lengthy approval and funding timelines hinder the ability of VHA to meet the identified space requirements to keep up with Veteran demand and invest in facilities updates that align with changing models for care. VA has recently established the Strategic Capital Investment Plan (SCIP), a systematic approach to approve capital projects and allocate funding. However, the process does not yet ensure full alignment with VA strategy, include rigorous business case scrubbing, or incorporate feedback on past project outcomes into the capital program assessment.

VA construction costs are similar to other public agencies in most cases, but double private industry best practice, and VA time-to-complete exceeds both public and private peers. Increased design requirements resulting from resilience, energy, security and community mandates increase the initial cost of projects over the private sector. Frequent design changes driven by users before construction contract award and during construction further increase the costs of projects and contribute to construction delays. Additionally, project teams are designed and staffed to support compliance requirements but these structures have resulted in reduced accountability for project delivery outcomes and a limited ability to develop solutions to manage cost overruns and schedule delays.

The leasing program is not effectively enabling VHA to provide facilities where and when they are required or at a reasonable cost for major leases. Lease timelines preclude VHA from benefitting from the speed and flexibility that leasing typically provides, often taking more than twice as long as private sector benchmarks. The leasing program typically achieves per square foot costs comparable to market prices for small and medium sized facilities, however, for larger build-to-suit facilities which are impacted by the same type of design and construction challenges seen in owned facilities we observed rents clustered at 40 to 50 percent higher than private sector benchmarks.

Facility management costs across VHA exceed those at comparable medical facilities. Facility management costs, including recurring maintenance and environmental services, are on the average two to three times higher than comparable private medical facilities, largely due to in-house management of these services rather than utilization of lower cost external service contracts. Facility management costs and practices are also highly variable across VHA facilities, with little incentive for individual stations to adopt cost effective measures.

Recommendations for consideration

Achieving best practice levels of performance in each of the assessment areas would require an overhaul of VA's capital program and supporting organization. Through our research, we have identified best practices from capital management organizations around the world that could be deployed to improve the total performance of capital programs of the scale and complexity of VA's. The cumulative improvement value of deploying all of these best practices in a single

---

organization could result in savings up to 40 percent.[136] However, even world class capital management organizations do not succeed in deploying all of these best practices consistently across their organizations, which illustrates the scale of the challenge. Shifts in the model of care delivery, lengthy approval processes, organizational health concerns, and strained budgets have combined to make capital management and delivery a formidable task for VA, and even the most ambitious transformation effort at VA may not achieve this total potential. As a result, we have estimated the total potential improvement opportunity for VA to be up to 25–35 percent.

Detailed recommendations for improving the capital program can be found in Sections 5 through 9, for each of the deep dives on core assessment areas. These recommendations fall into the following main opportunity areas:

VA should improve project selection and refine its project portfolio. VA should refine the SCIP process to rationalize and prioritize capital requirements by ensuring that space, energy, and condition criteria are reflective of the most critical items that contribute to Veteran care. The SCIP process, initiated four years ago, advanced VA capital project selection by creating a standardized methodology to review and approve projects which did not previously exist, but further steps are needed to improve the approach. These include a careful assessment of standards and a modification of the criteria for project selection. By focusing the criteria and approval processes for capital projects, VA could concentrate capital spending on strategic priorities and accelerate approval timelines. Capital project planning should also incorporate feedback on performance and outcomes from past projects to determine which capital programs respond to Veteran needs in the most cost effective manner possible. This would help enable a vital link between portfolio planning, project execution, and achievement of the desired outcomes in Veteran care.

VA should streamline project delivery across all construction types and leasing. VA should comprehensively address the root causes (for example, specifications, approval processes, project governance structures, team capabilities and composition) currently leading to consistent overruns in cost and schedule for construction projects and lengthy timelines for leases. This begins with modernizing and rationalizing design standards in keeping with current innovations in health care. A clear stage-gate process should be implemented to manage scope and design changes in the planning and design phases of projects and to limit scope and design changes that occur after a project receives funding and during construction. The recently launched Capital Program Requirements Management Process (CPRMP) introduced reviews during the design process to manage scope changes, another positive step which should be further developed and rolled out. To increase ownership and accountability, project delivery teams should be restructured with clear roles and responsibilities, well-defined handoffs, and adequate staffing levels. Additionally, contracting and other supporting entities should be

---

[136] "Infrastructure Productivity How to save $1 trillion a year," by McKinsey & Company (January 2013). This report includes more than 400 case examples from around the world. For this assessment, estimated savings have been adjusted to reflect requirements and constraints specific to VA.

accountable and equipped to support a fast-paced project environment and facilitate the needs of construction projects and leases.

VHA should ensure proposed projects make the most of existing infrastructure. VHA could improve the effectiveness of its infrastructure through incorporating a total cost of ownership assessment approach into design, capital planning, and facility management. This requires evaluating the operational cost implications of design choices and pursuing opportunities to optimize capital and operating costs simultaneously. Space planning programs should regularly evaluate underutilized and vacant space to identify opportunities for increased utilization or to actively divest unusable properties.

In addition to taking steps to address the above recommendations, VHA should consider more transformative options as needed to address the remaining unfunded capital requirement. If VA is able to successfully implement current improvement initiatives, act on the additional recommendations listed above, and demonstrate best practice performance, VA could potentially reduce its total capital need to $33 to $38 billion over the next 10 years. Based on average funding of $16–26 billion over 10 years, an unfunded gap of $7 to 22 billion would still exist. To close this remaining gap, funding would have to increase and VA will need to consider more transformative options. When other institutions have faced similar capital shortfalls, they have considered a range of strategic and business model redesign options in addition to implementing best practices in capital project delivery. This report lays out several strategic approaches for further consideration by VHA, including:

- *Maximize operational efficiency*. Operating improvements, such as extending operating hours, improving scheduling efficiency, increasing tele-health options, and reducing average length of stay, can provide non-capital solutions to meeting workload needs. The operating recommendations in Assessments E, F, G, and H may contribute to addressing VHA's capital need.

- *Reassess how and where to best serve Veterans*. When facing similar circumstances to VA, other health care organizations have considered strategic operating changes that result in a realignment in their capital portfolios. This could potentially include geographic realignment, community partnerships, or a shift in service offerings. Assessments B and C may offer some further insights.

- *Explore alternative vehicles for capital delivery*. Alternative models of providing facilities have proved productive for some organizations. These models include contracting out capital investment, outsourcing facility management, and establishing innovative public-private partnerships.

In summary, VA has taken steps to improve its capital program, but much more is required given the scale of the capital need and the gap between current performance and best practice. Even with the most ambitious expectations for improving the capital program, VA will likely face a major funding gap over the next decade that will require a combination of additional funding and transformative changes to operations in order to ensure that Veterans receive the level and quality of care VA has committed to provide.

This page intentionally left blank.

Appendix L   Leadership

L.1   Scope

Part L ("Assessment L"), Section 201 of the Veterans Access, Choice, and Accountability Act of 2014 ("The Veterans Choice Act") required an independent assessment of how leadership influences the Veterans Health Administration's (VHA's) ability to accomplish its mission. The law required an assessment of:

> "(L) The competency of leadership with respect to culture, accountability, reform readiness, leadership development, physician alignment, employee engagement, succession planning, and performance management."

Congress has thus directed that VHA leadership be viewed in the context of the eight separate but related elements of leadership, each of which is addressed in detail in the assessment, as summarized below.

The broad scope of the law's mandate represented an important opportunity to understand leadership at VHA, including its executive organization, Medical Center facility leaders, and regional network administrators. The scope of this assessment focuses on the senior leadership of VHA at each VA Medical Center (VAMC), Veterans Integrated Service Network (VISN), VA Central Office (VACO), and VHA Central Office (VHACO). The senior leadership at the VAMC and VISN are defined as the "Quadrad" or "Pentad" leaders: Director, Associate Director, Chief of Staff, Associate Director for Patient Care Services, and Assistant Director for Operations, if applicable.[137]

The assessment utilizes data and analysis from a survey of all VHA employees about its leadership beliefs and practices, 39 site visits and more than 300 interviews with VHA leaders across the country and analysis of existing VHA and other federal data. We then synthesized the findings and recommendations across the eight elements to identify patterns, points of interaction, and interdependencies, resulting in seven cross-cutting themes and six overarching recommendations.

L.1.1   Findings

Reviewing all eight elements described in Section 201 Assessment L provides an opportunity to create an integrated perspective of leadership at VHA. The scale of VHA is vast, and it is difficult to fully capture all the nuances and variability that exist throughout the system. Areas of excellence exist across the system, including some inspiring and resilient leaders, front-line systems redesign teams, and homegrown innovation. We touch on these throughout the full report. However, most areas of the organization show a highly risk-averse culture; lack of role clarity; fragmentation and organizational silos; and breakdowns in communication, accountability, and key processes that impair the organization's ability to deliver the mission.

---

[137] The terms Quadrad and Pentad are used interchangeably throughout this report as they are at VHA.

Our efforts have yielded a complex portrait of leadership practices reflecting leaders at VHA who are diverse in their approach, experience, skill, and effectiveness. They are operating in a system without common agreed upon leadership goals, methods and processes. Examining each of the eight elements, we identified the following seven themes about leadership today at VHA:

1. **An expanding scope of VHA activities has led to confusion around leadership priorities and the strategic direction of VHA.** The organization's focus has expanded and shifted over time, and it is unclear what the priorities are, and unclear when they will shift again. Over time, VHA has expanded into the delivery of a wide range of clinical services, as well as various social pursuits. The organization is not configured or resourced to deliver this expanding scope of activities, and it is unclear where the boundaries of the mission lie. VHA is also treated by oversight entities and external stakeholders as both a hospital system and a traditional government agency. This unique complexity of VHA is not supported by equally unique performance expectations, operational flexibility, and supporting tools.

2. **From the point of view of leaders and employees, the VHA organization is intensely, unnecessarily complex due to lack of a clear operating model, limited role clarity, fragmentation of authority, and overlapping responsibilities**. This lack of clarity around operating model, roles and responsibilities extends across VAMCs, the VISNs, and Central Office. The issue is exacerbated by a cultural context that is often unable to work effectively across chains of command, except where all parties concur. Fragmentation and silos exist across the system and within each tier of the organization. Many key support functions, such as human resources or contracting, suffer from this, resulting in service too slow to meet the needs of the mission. Meanwhile, the sheer number of operational performance measures in many cases overwhelms and makes it difficult to know and focus on what is most important.

3. **The broader VHA culture is characterized by risk-aversion and distrust, resulting in an inability to improve performance consistently and fully across the system**. At almost every facility visited, at least one leader interviewed mentioned that risk-aversion and a reluctance to "speak up" were significant issues. Three out of every four leaders interviewed at VISNs in which site visits were conducted echoed this concern (VHA interviews, 2015). A general aversion to speak up or take risks originates from: a) trying to perform in a heavily siloed organization; b) fear that raising issues will result in punitive actions toward the individual or addition of significant workload with no additional support; and c) insufficient reward for those trying to make improvements. This culture permeates across all levels of the organization – from the front-lines, to Medical Center leaders, to people at Central Office. This culture of risk aversion also hinders great ideas from spreading. A lack of enterprise-wide incentives and mechanisms for knowledge-sharing within or across the system yields pockets of innovation but not broader system-wide adoption (VHA interviews, 2015; VHA OHI survey, 2015).

4. **VHA leadership faces a workforce that appears to be steadily losing its motivation.** Caring for Veterans is a value that powerfully motivates VHA leaders and employees alike – however, this commitment alone is insufficient to fuel the organization's motivation and performance. Other sources of motivation such as a great work environment, job satisfaction, or working with an inspiring team have eroded in recent years (VHA interviews, 2015). Physicians are only partially aligned with the various demands put on them. In a changing environment in which VHA competes with other health care organizations for top talent, a value proposition that relies primarily on the intrinsic reward of caring for Veterans cannot make up for the erosion of other sources of employee motivation to meet the VHA mission.

5. **The performance of a particular VAMC hinges to a large degree on the capability of its Director and the executive leadership team; yet these leaders are "on their own" in many ways.** VAMC Directors often lack competent and timely assistance from support functions (including HR for disciplining, hiring employees, planning for succession; construction; IT; and contracting). Support from VISN and VHACO is variable and often limited. Directors are left to navigate their own career progression and development (VHA interviews, 2015).

6. **VHA leadership attention is consumed by addressing crises that have occurred in the past, at the expense of preparing for tomorrow's opportunities**. The number of directives for which leaders are accountable, coupled with heightened scrutiny from internal and external sources, compels leaders to spend much of their time reacting to crises and completing action items from above. Bottom-up innovation and consultative leadership are not well-developed, and there is a heavy reliance on top-down directives, exacerbated by the growth of Central Office Program Offices (VHA OHI survey, 2015; VHA interviews, 2015).

7. **The leadership pipeline is not robust enough to meet VHA's current and future needs, a function both of inadequate succession planning and unfocused leadership development efforts**. As of March 2015, 16 percent of VAMC Quadrad and VISN Network Director positions are vacant or have acting leaders. Twenty-three VA Medical Centers (16 percent) do not have a permanent Director. Nine VISN Network Directors (43 percent) are Acting (VHA Office of Workforce Services, 2015). Leadership positions are increasingly unattractive to the next generation of VHA leaders, which contributes to the difficulty in filling leadership openings (VHA interviews, 2015). VHA is currently experiencing a large and widespread number of current vacancies and upcoming retirements in key leadership roles, and open positions remain unfilled due to a lack of qualified candidates. Meanwhile, VHA's lack of a comprehensive approach to leadership development—experiential, relational, and training—has resulted in leaders with uneven preparation for their future roles. Multiple competency models and frameworks are in use, and VHA's formal programs are not linked to career paths, not well-coordinated, and thus do not effectively bolster VHA's talent pipelines (VHA Office of Workforce Services, 2015; VHA interviews, 2015).

The views, opinions, and/or findings contained in this report are those of the assessment team and should not be construed as an official government position, policy, or decision.

This report's findings indicate that immediate action is required. The challenges of the current culture and operating environment, the deteriorating atmosphere for leaders, and the intense public scrutiny suggest that sustaining an effective operation and an engaged employee and leadership base to serve six million Veteran enrollees each year will require a fundamental shift achieved through a bold, integrated, multi-year transformation.

L.1.2   Recommendations

The scale of the transformation needed to address the findings above has few precedents in the private or public sector. VHA employs one in nine federal civilian employees (OPM, Historical Federal Workforce Tables and FedScope, 2015). It is both the largest hospital system and the largest training ground for health care providers in the country, training tens of thousands of clinicians each year (VA, Office of Academic Affiliations, 2015). And the nature of the current system – with hundreds of unique locations, partnerships, and performance measures – only increases the complexity of the opportunity.

Given this challenge, the recommendations summarized below should not be approached like a checklist of individual and incremental performance improvements. Most transformations treated in this manner fail (Keller and Price, 2011). Instead, VHA should systematically implement these recommendations in a comprehensive, multi-year transformation program. The transformation program needs to clearly define its aspiration state, determine what is needed to meet this state, be housed in a formal change program, protect or build on best practices and high performing pockets, and ensure timely implementation faithful to the original aspiration.

These recommendations fall into six main opportunities:

1. **Galvanize VHA leaders around a clear strategic direction.**

   Decide and communicate the strategic direction of VHA going forward. The strategy could take a variety of forms, but there needs to be clarity within VHA of where the organization is headed, and this needs to be communicated throughout the organization and understood by all leaders and employees. We do not seek to define the strategic direction here, but clear strategic direction will be critical as the organization moves forward and works to implement the recommendations laid out herein.

2. **Stabilize, grow, and empower leaders.**

   VHA should strengthen its leadership foundation, both today's and tomorrow's. VHA should focus in the near term on increasing leadership stability and readiness by filling vacancies with high-quality leaders, improving the attractiveness of the role to prospective leaders, and ensuring leaders are ready to assume their roles. In the medium term they should build a coordinated people development strategy that connects top performers with the right opportunities and generates a robust pipeline of leaders through a formal succession planning program and a coordinated set of development opportunities. Efforts should be made to build sustained leadership continuity across the system, including considering longer tenures for key leaders, such as Medical Center Directors and select roles at VHACO. This is necessary to have the

authority, accountability, ownership and time needed to stabilize the organization, strengthen its health and performance, and shepherd the transformation.

3. **Redesign VHA's operating model to create clarity for decision-making authority, prioritization, and long-term support.**

   VHA should immediately lead an effort to clearly define roles and decision rights at each level and increase coordination within Central Office, refocusing the role of Central Office to managing outcomes and providing "corporate center"-like support to the field. The Central Office should prioritize, integrate, and actively provide support to the various initiatives and policies being implemented by the field. The net effect of the redesign should be a Central Office that is highly valued by the field for the expertise, services, and strategic direction it provides.

4. **Focus and simplify performance management to clarify accountability and actively support the mission.**

   Within six months, VHA should complete an effort to develop an integrated and balanced performance scorecard for VAMCs focusing on a smaller number of core metrics that roll up to support the broader enterprise view. These metrics should be designed to focus more on the mission and encourage cross-functional collaboration and should be carefully cascaded. This requires moving from hundreds today (over 382 alone in the National Performance Measures Report) to no more than 20 that cover quality, safety, patient experience, operational efficiency, finance, and human resources. The resulting data should be made readily available and accessible agency-wide with proper procedures in place to ensure quality.

5. **Rebuild a high-performing, healthy culture by cultivating greater employee collaboration, ownership, and accountability to accomplish the mission.**

   Culture is often described simply as "how things are done around here," and changing the VHA culture will need to happen at all levels of VHA: VHACO, VISN, and the VAMC level, as well as within the context of VA broadly. VHACO should consider how to integrate their efforts so the workforce is involved and experiences a coherent set of messages, policies, and support from VHACO. The VISNs should lead the VAMC leaders by sharing best practices, demanding steady improvement, and encouraging innovation. VAMC leaders will need to role model the change, describe why the culture must change, reinforce desired behaviors (and discourage unhelpful ones), and provide leaders and employees alike with the coaching, training and tools they will need to succeed. In our experience this is feasible, but there is no simple or fast way, and it will require a dedicated performance transformation effort.

6. **Redesign the human resources function as a more responsive customer service-focused entity.**

   VHA, with the full support and backing of VA, should begin an effort in the next 12 months to transform the human resources (HR) function to be more responsive to meeting the needs of VAMC leadership, more efficient, and more customer service-

focused. Although a comprehensive examination of HR was not within scope of Assessment L, systematic HR challenges were identified that need to be addressed through a transformation of the HR function. Such a transformation will likely require redesigning key processes (e.g., hiring), shifting the mindsets of HR cadre from compliance to effectiveness, training HR and its customers on key roles and responsibilities, and rationalizing its technology systems.

The complete Assessment L report is available in Volume II.

Appendix M   Outreach

Over the past 10 years, many assessments of VHA have been conducted from different points of view, and many thoughtful solutions by experts from inside and outside the department have been provided. However, while some incremental changes may have been made, the real desired impact of a highly coordinated, enterprise-level, successful transformation of VHA has not been achieved.

MITRE conducted an analysis of selected health care systems that successfully transformed into high-functioning and performing health care systems. This effort included interviews with executive teams from 27 large U.S. health systems and also included visits to selected health systems.

Some of the lessons learned from these engagements include:

A sense of urgency: Many of the largest health systems faced financial crises in the late 1990s and early 2000s due to a dramatically changed medical payment landscape. Several leaders of the selected health care systems found their institutions were not profitable, and they faced a critical decision: either change management models from a fee-for-service model or go out of business. Within this crucible, new leaders often emerged. They recognized both the need for change and the importance of communicating the urgency of that change to all levels of the organization and to organizational stakeholders.

Empowered visionary leaders and new missions: The individuals who emerged to lead these institutions had similar characteristics. They were visionary and charismatic leaders who were fully committed to the new mission and exemplified the behaviors required to achieve that mission. Their leadership teams described them as actively shaping the culture, and they provided focus on change and freedom to fundamentally alter processes. They consistently were "hard on processes, not on people," meaning they built a culture that was developmental and transparent rather than punitive. Employee morale, motivation, and retention improved as they were empowered to remove non-mission essential burdens and increase time and resources for core mission activities. Leaders were routinely seen on the front lines of care and in regular meetings with cross-functional teams to resolve barriers to mission success and reinforce the vision and culture.

Sustained and time-consuming process: The institutions that were visited consistently pointed out that what they are doing to realize change is not a special project; rather, it is a management system. Each found that it took about three years for physicians and staff to recognize that the changes occurring were not the "change du jour." They also shared that after five to six years, staff and providers within the health systems felt the changes were successful and enduring. Along the way, it was important to experiment, tolerate mistakes, and learn from them and encourage employee engagement to instill a new culture within the organization.

A new management system that adheres to a patient-centric culture and value system: The new management models were patient centered and required working with physician leadership and payers to reshape clinical and operational processes around the patient. Leaders were selected carefully for performance, not on résumés. Leadership and staff were

empowered, recognized, and rewarded for challenging care decisions and modifying processes that did not add value to patients care.

Supportive and knowledgeable governance: The leaders of these high-performing systems often had a supportive and knowledgeable Board of Trustees. Some trustees had led similar successful transformations in other industries. This type of governance structure ensured adherence to a single clear architecture and the ongoing integrity of the health care system's mission and operating principles. The board also often had compacts with practicing physicians, leadership, and management. In addition, the leaders were given a wide berth and sufficient time (more than five to seven years) to execute needed reforms.

Transparent data-driven management system: The systems consistently demonstrated transparent use of data that was shared from the chief executive officer to front-line staff, clarifying how performance is measured and ensuring that everyone worked from the same accurate information. Many compared the performance data of similar teams and staff members to promote sharing best practices. Most health care systems focused on continuous improvement that originated within teams rather than setting team targets from higher levels in the organization. Lastly, "red" metrics were used as an opportunity for management to focus and fix, rather than blame and punish.

Methodology: In January 2015, CAMH gathered publicly available listings of the largest U.S. health care systems (by number of employees), health insurers (by market share), and organizations representing medical device manufacturers and pharmaceutical companies. CAMH leveraged its network of health care executives to add additional prominent health care systems with national reputations and then generated a convenience sample of 37 private-industry institutions to use for data collection. Upon inquiry, executive leaders from 27 of the selected U.S. health care organizations were available to be interviewed.

MITRE Officers and leaders conducted 30–60 minute interviews with the executives from selected health care systems to inform them of the Veterans Choice Act 201 assessments and to gain their insight, experience, and recommendations of best practices that, if adopted, would positively impact the Veterans health care delivery system. An interview guide was developed for each institution that targeted the Veterans Choice Act 201 assessment topic areas and was tailored to center on strengths (by reputation) of the institution being interviewed.

From March to June 2015, CAMH Choice Act Program Teams conducted site visits to selected health systems. Teams of 5–18 members from CAMH's Choice Act Program attended these one- to three-day site visits; participated in the discussions with executive leaders, administrators, and clinicians; and completed facility tours and observations. These site visits have included:

- Kaiser Permanente
- Cleveland Clinic
- Virginia Mason Hospital and Medical Center
- Geisinger Health System.

U.S. Health Care Industry Leaders: The following organizations gave freely of their time and provided access to their systems and their senior leadership teams for in-depth discussions.

During those conversations, they shared their experience, perspectives, health initiatives, and viewpoints of best practices in health care that could be adopted by the Veterans health care system. Several also provide on-site visits to examine their clinical and administrative operations. Many spoke of their thankfulness for our nation's Veterans and their pleasure to support the VA in making improvements to Veterans' care.

- Adventist Health System
- Aetna, Inc.
- American Pharmacists Association
- Anthem, Inc.
- Ascension Health
- Blue Cross Blue Shield of Massachusetts
- Blue Shield of California
- Cleveland Clinic
- Geisinger Health System
- Hospital Corporation of America, Inc.
- Humana Subsidiaries: Government Business - Humana Veterans (subsidiary of Humana Government Business) and Concentra
- Intermountain Health care
- Independence Blue Cross Group
- New York City Health and Hospital Corporation
- Johns Hopkins Medicine
- Kaiser Permanente
- Medical Device Manufacturers Association
- New York-Presbyterian Health care System
- NYU Langone Medical Center
- Partners Health care, including executives from Brigham and Women's Hospital and Mass General Hospital System
- Pharmaceutical Research and Manufacturers of America
- Providence Health & Services
- Tenet Health care Corporation
- ThedaCare Center for Health care Value
- University of California Health Sciences and Services
- University of Texas System
- Virginia Mason Hospital & Medical Center

Veterans Service Organizations (VSOs): The VSOs listed below shared with us data, reports, surveys, and their understanding of their constituents' health care needs. They provided the voice of the Veterans that the health care system serves. We are grateful to them for their support and for their daily commitment and service to Veterans.

- The American Legion
- American Veterans
- Disabled American Veterans
- Iraq and Afghanistan Veterans
- Military Officers Association of America
- Military Order of the Purple Heart of the U.S.A., Inc.
- Paralyzed Veterans of America
- Veterans of Foreign Wars of the United States
- Vietnam Veterans of America
- Wounded Warrior Project

Appendix P   Section 201 of the Veterans Choice Act

Section 201: Independent Assessment of the Health Care Delivery Systems and Management Processes of the Department of Veterans Affairs.

(a) INDEPENDENT ASSESSMENT.—

(1) ASSESSMENT.—Not later than 90 days after the date of the enactment of this Act, the Secretary of Veterans Affairs shall enter into one or more contracts with a private sector entity or entities described in subsection (b) to conduct an independent assessment of the hospital care, medical services, and other health care furnished in medical facilities of the Department. Such assessment shall address each of the following:

(A) Current and projected demographics and unique health care needs of the patient population served by the Department.

(B) Current and projected health care capabilities and resources of the Department, including hospital care, medical services, and other health care furnished by non-Department facilities under contract with the Department, to provide timely and accessible care to veterans.

(C) The authorities and mechanisms under which the Secretary may furnish hospital care, medical services, and other health care at non-Department facilities, including whether the Secretary should have the authority to furnish such care and services at such facilities through the completion of episodes of care.

(D) The appropriate system-wide access standard applicable to hospital care, medical services, and other health care furnished by and through the Department, including an identification of appropriate access standards for each individual specialty and post-care rehabilitation.

(E) The workflow process at each medical facility of the Department for scheduling appointments for veterans to receive hospital care, medical services, or other health care from the Department.

(F) The organization, workflow processes, and tools used by the Department to support clinical staffing, access to care, effective length-of-stay management and care transitions, positive patient experience, accurate documentation, and subsequent coding of inpatient services.

(G) The staffing level at each medical facility of the Department and the productivity of each health care provider at such medical facility, compared with health care industry performance metrics, which may include an assessment of any of the following:

(i) The case load of, and number of patients treated by, each health care provider at such medical facility during an average week.

(ii) The time spent by such health care provider on matters other than the case load of such health care provider, including time spent by such health care provider as follows:

(I) At a medical facility that is affiliated with the Department.

The views, opinions, and/or findings contained in this report are those of The MITRE Corporation and should not be construed as an official government position, policy, or decision.

(II) Conducting research.

(III) Training or supervising other health care professionals of the Department.

(H) The information technology strategies of the Department with respect to furnishing and managing health care, including an identification of any weaknesses and opportunities with respect to the technology used by the Department, especially those strategies with respect to clinical documentation of episodes of hospital care, medical services, and other health care, including any clinical images and associated textual reports, furnished by the Department in Department or non-Department facilities.

(I) Business processes of the Veterans Health Administration, including processes relating to furnishing non- Department health care, insurance identification, third-party revenue collection, and vendor reimbursement, including an identification of mechanisms as follows:

(i) To avoid the payment of penalties to vendors.

(ii) To increase the collection of amounts owed to the Department for hospital care, medical services, or other health care provided by the Department for which reimbursement from a third party is authorized and to ensure that such amounts collected are accurate.

(iii) To increase the collection of any other amounts owed to the Department with respect to hospital care, medical services, and other health care and to ensure that such amounts collected are accurate.

(iv) To increase the accuracy and timeliness of Department payments to vendors and providers.

(J) The purchasing, distribution, and use of pharmaceuticals, medical and surgical supplies, medical devices, and health care related services by the Department, including the following:

(i) The prices paid for, standardization of, and use by the Department of the following:

(I) Pharmaceuticals.

(II) Medical and surgical supplies.

(III) Medical devices.

(ii) The use by the Department of group purchasing arrangements to purchase pharmaceuticals, medical and surgical supplies, medical devices, and health care related services.

(iii) The strategy and systems used by the Department to distribute pharmaceuticals, medical and surgical supplies, medical devices, and health care related services to Veterans Integrated Service Networks and medical facilities of the Department.

(K) The process of the Department for carrying out construction and maintenance projects at medical facilities of the Department and the medical facility leasing program of the Department.

(L) The competency of leadership with respect to culture, accountability, reform readiness, leadership development, physician alignment, employee engagement, succession planning, and performance management.

(2) PARTICULAR ELEMENTS OF CERTAIN ASSESSMENTS.—

(A) SCHEDULING ASSESSMENT.—In carrying out the assessment required by paragraph (1)(E), the private sector entity or entities shall do the following:

(i) Review all training materials pertaining to scheduling of appointments at each medical facility of the Department.

(ii) Assess whether all employees of the Department conducting tasks related to scheduling are properly trained for conducting such tasks.

(iii) Assess whether changes in the technology or system used in scheduling appointments are necessary to limit access to the system to only those employees that have been properly trained in conducting such tasks.

(iv) Assess whether health care providers of the Department are making changes to their schedules that hinder the ability of employees conducting such tasks to perform such tasks.

(v) Assess whether the establishment of a centralized call center throughout the Department for scheduling appointments at medical facilities of the Department would improve the process of scheduling such appointments.

(vi) Assess whether booking templates for each medical facility or clinic of the Department would improve the process of scheduling such appointments.

(vii) Assess any interim technology changes or attempts by Department to internally develop a long-term scheduling solutions with respect to the feasibility and cost effectiveness of such internally developed solutions compared to commercially available solutions.

(viii) Recommend actions, if any, to be taken by the Department to improve the process for scheduling such appointments, including the following:

(I) Changes in training materials provided to employees of the Department with respect to conducting tasks related to scheduling such appointments.

(II) Changes in monitoring and assessment conducted by the Department of wait times of veterans for such appointments.

(III) Changes in the system used to schedule such appointments, including changes to improve how the Department—

(aa) measures wait times of veterans for such appointments;

(bb) monitors the availability of health care providers of the Department; and

(cc) provides veterans the ability to schedule such appointments.

(IV) Such other actions as the private sector entity or entities considers appropriate.

(B) MEDICAL CONSTRUCTION AND MAINTENANCE PROJECT AND LEASING PROGRAM ASSESSMENT.—In carrying out the assessment required by paragraph (1)(K), the private sector entity or entities shall do the following:

(i) Review the process of the Department for identifying and designing proposals for construction and maintenance projects at medical facilities of the Department and leases for medical facilities of the Department.

(ii) Assess the process through which the Department determines the following:

(I) That a construction or maintenance project or lease is necessary with respect to a medical facility or proposed medical facility of the Department.

(II) The proper size of such medical facility or proposed medical facility with respect to treating veterans in the catchment area of such medical facility or proposed medical facility.

(iii) Assess the management processes of the Department with respect to the capital management programs of the Department, including processes relating to the methodology for construction and design of medical facilities of the Department, the management of projects relating to the construction and design of such facilities, and the activation of such facilities.

(iv) Assess the medical facility leasing program of the Department.

(3) TIMING.—The private sector entity or entities carrying out the assessment required by paragraph (1) shall complete such assessment not later than 240 days after entering into the contract described in such paragraph.

(b) PRIVATE SECTOR ENTITIES DESCRIBED.—A private entity described in this subsection is a private entity that—

(1) has experience and proven outcomes in optimizing the performance of the health care delivery systems of the Veterans Health Administration and the private sector and in health care management; and

(2) specializes in implementing large-scale organizational and cultural transformations, especially with respect to health care delivery systems.

(c) PROGRAM INTEGRATOR.—

(1) IN GENERAL.—If the Secretary enters into contracts with more than one private sector entity under subsection (a), the Secretary shall designate one such entity that is predominately a health care organization as the program integrator.

---

(2) RESPONSIBILITIES.—The program integrator designated pursuant to paragraph (1) shall be responsible for coordinating the outcomes of the assessments conducted by the private entities pursuant to such contracts.

(d) REPORT ON ASSESSMENT.—

(1) IN GENERAL.—Not later than 60 days after completing the assessment required by subsection (a), the private sector entity or entities carrying out such assessment shall submit to the Secretary of Veterans Affairs, the Committee on Veterans' Affairs of the Senate, the Committee on Veterans' Affairs of the House of Representatives, and the Commission on Care established under section 202 a report on the findings and recommendations of the private sector entity or entities with respect to such assessment.

(2) PUBLICATION.—Not later than 30 days after receiving the report under paragraph (1), the Secretary shall publish such report in the Federal Register and on an Internet website of the Department of Veterans Affairs that is accessible to the public.

(e) NON-DEPARTMENT FACILITIES DEFINED.—In this section, the term ''non-Department facilities'' has the meaning given that term in section 1701 of title 38, United States Code.

Appendix Q   Blue Ribbon Panel

The Blue Ribbon Panel members are listed here, along with their biographies.

Dr. Brett Giroir (Panel Chair)	
Dr. Gail Wilensky (Panel Co-Chair)	
Dr. Katrina Armstrong	Dr. Debra Barksdale
Dr. Ronald R. Blanck	Prof. W. Warner Burke
Dr. Christine Cassel	GEN(R) Peter W. Chiarelli
Mr. George Halvorson	Mr. Robert L. Mallett
Dr. Robert Margolis	Dr. George Poste
Dr. Robert C. Robbins	Dr. Mark D. Smith
Dr. Glenn D. Steele, Jr.	Dr. Beth Ann Swan

Dr. Katrina Armstrong

Katrina Armstrong, M.D., MSCE, a world-renowned investigator in the areas of medical decision-making, quality of care, and cancer prevention and outcomes, is Physician-in-Chief of the Massachusetts General Hospital Department of Medicine, and Professor of Medicine at Harvard Medical School. Focusing at the interface of genomics, cancer and social policy, she has translated genomics advances into improvements in cancer control and identified novel mechanisms underlying cancer disparities. She leads one of the premier departments of medicine in the U.S. today, and has a deep understanding of what is needed to deliver exemplary clinical care.

Dr. Debra Barksdale

Dr. Debra J. Barksdale is Professor and Director of the DNP program at the University of North Carolina at Chapel Hill (UNC-CH). She is certified as a family nurse practitioner (NP), an adult NP, and a nurse educator. She is a Fellow of the American Academy of Nurse Practitioners and the American Academy of Nursing. She has over 20 years of NP experience and has been a NP in urgent care, primary care, home care and care of the underserved. On September 23, 2010, Dr. Barksdale was one of 19 members appointed to the 21 member Board of Governors for the new Patient-Centered Outcomes Research Institute (PCORI) by the U.S. Government Accountability Office under the Obama Administration. She is the only nurse appointed to the PCORI Board.

Dr. Ronald R. Blanck

Lt. Gen. Ronald R. Blanck, D.O., USA (Ret.), was the 39th Surgeon General of the United States Army, from 1996–2000. He was president of the University of North Texas Health Science

Center at Fort Worth from 2000 to 2006. He currently serves as Chairman of the Board of Regents of the Uniformed Services University of the Health Sciences. He began his military career in 1968 as a medical officer and battalion surgeon in Vietnam. He retired 32 years later as the Surgeon General of the U.S. Army and commander of the U.S. Army Medical Command, with more than 46,000 military personnel and 26,000 civilian employees throughout the world.

Prof. W. Warner Burke

Warner Burke, Ph.D,. is the E. L. Thorndike Professor of Psychology and Education and Editor of the Journal of Applied Behavioral Science at Teachers College, Columbia University. A social-organizational psychologist (Ph.D., University of Texas, Austin), Dr. Burke is currently engaged in teaching, research, and consulting. He teaches leadership and supervision and organization change. His research focuses on leadership, multirater feedback, organization change, and learning agility. Prof. Burke co-directs the Eisenhower Leader Development Program, an MA degree for Army officers jointly sponsored by Teachers College, Columbia University and the US Military Academy at West Point. He is the former Chair of the Department of Organization and Leadership at Teachers College, Columbia University. Among his many awards is the Public Service Medal from the National Aeronautics and Space Administration.

Dr. Christine Cassel

Christine K. Cassel, M.D., President and CEO of the National Quality Forum, is a leading expert in geriatric medicine, medical ethics, and quality of care. She is one of the world's leading experts on clinical quality. Dr. Cassel previously served as President and CEO of the American Board of Internal Medicine (ABIM), the ABIM Foundation, and Dean of the School of Medicine at Oregon Health Sciences University. Dr. Cassel is one of 20 scientists (and the only M.D.) chosen by President Obama to serve on the President's Council of Advisors on Science and Technology (PCAST), which advises the President in areas where an understanding of science, technology, and innovation is key to forming responsible and effective policy. She is the co-chair and physician leader of PCAST working groups that have made recommendations to the President on issues relating to health information technology and ways to promote scientific innovation in drug development and evaluation. In addition to having chaired influential Institute of Medicine (IOM) reports on end-of-life care and public health, she served on the IOM's Comparative Effective Research Committee mandated by Congress to set priorities for the national CER effort (PCORI).

Gen. Peter W. Chiarelli

Peter W. Chiarelli is a retired United States Army general who served as the 32nd Vice Chief of Staff of the U.S. Army from August 4, 2008 to January 31, 2012. As former vice chief of staff of the Army, Gen Chiarelli understands the needs of the Veteran, understands the issues of the hand-off from DoD care to VHA care for the Veterans, and has a deep personal interest in improving care for those Veterans who have experienced traumatic brain injury and post-traumatic stress.

Dr. Brett Giroir (Panel Chair)

Brett Giroir, M.D., is currently Senior Fellow at the Health Policy Institute of the Texas Medical Center, and former CEO of the Texas A&M Health Science Center, a premier assembly of colleges devoted to educating health professionals and advancing research in medicine, dentistry, public health, nursing, and pharmacy. He is a global authority on health care and life sciences innovation, having served diverse roles including Director of the Defense Science Office at DARPA, Principal Investigator of the DHHS Center for Innovation responsible for producing 50 million doses of vaccine against pandemic influenza, and Director of the Texas Task Force on Infectious Diseases chartered to lead the state's Ebola response and recommend policy changes within the state.

Mr. George Halvorson

Mr. George Halvorson served as chairman and chief executive officer of Kaiser Permanente from 2002–2013. Prior to serving as Kaiser Permanente CEO, Mr. Halvorson was the president and CEO of Health Partners in Minnesota for 17 years. He brings world-class leadership experience and expertise to the Panel, particularly in terms of leading a very large vertically integrated health care delivery system. He also brings connectivity to, and relationships with, many other expert health care leaders.

Mr. Halvorson currently serves as the Chair and CEO for the Institute of InterGroup Understanding and has a four year appointment to Chair the State of California Commission for Children and Families.

Mr. Robert L. Mallett

Robert L. Mallett is currently a board member and President and CEO of Accordia Global Health Foundation, an organization dedicated to health systems strengthening in Sub-Saharan Africa. For much of his professional career, Mr. Mallett has served in the health sector as a board member of health centered nonprofit organizations and at industry-leading health care companies. He is formerly Executive Vice President & General Counsel, Public and Senior Markets Group, a division of United Health Group. Immediately prior to joining United Health Group, Mr. Mallett served as Senior Vice President, Worldwide Policy & Public Affairs, Pfizer Inc. At Pfizer, among other things, he co-led the company's efforts on enhancing global access to medicines and served as President of the Pfizer Foundation. Mr. Mallett has also enjoyed a stimulating career as a chief operating officer in both federal and local government. During the Clinton Administration, he served as Acting Secretary and Deputy Secretary of the U.S. Department of Commerce, and he was City Administrator and Deputy Mayor for Operations for the District of Columbia. He has been the Peter P. Mullen Visiting Professor of Law at Georgetown University, and a Visiting Professor at the John F. Kennedy School of Government at Harvard University. Mr. Mallett is a member of the Council on Foreign Relations and an elected Fellow of the National Academy of Public Administrators.

Dr. Robert Margolis

Robert Margolis, M.D., is former Co-Chairman of the Board, DaVita HealthCare Partners and CEO Emeritus of HealthCare Partners, LLC. Dr. Margolis served as the managing partner and CEO of HealthCare Partners from the formation of the company in 1992 through February 2014. Under Dr. Margolis' leadership, HealthCare Partners became a highly respected and innovative

physician-owned and operated medical group, independent physician association, and management services organization. Dr. Margolis has been on the leading edge of the managed care industry for more than 30 years.

Dr. George Poste

Dr. George Poste is the Del E. Webb Professor of Health Innovation and Chief Scientist of the Complex Adaptive Systems Initiative (CASI) at Arizona State University (ASU). This program integrates research in genomics, synthetic biology and high performance computing to study the altered regulation of molecular networks in human diseases to develop new diagnostic tests for precision (personalized) medicine and the remote monitoring of health status using miniaturized body sensors and mobile devices. From 1992–1999, he was Chief Science and Technology Officer and President, R&D, of SmithKline Beecham (SB). During his tenure at SB, he was associated with the successful registration of multiple drug, vaccine, and diagnostic products. He has served as a member of the Defense Science Board of the U.S. Department of Defense and currently serves on advisory committees for several U.S. government agencies in defense, intelligence, national security and health care.

Dr. Robert C. Robbins

Robert C. Robbins, M.D., became President and Chief Executive Officer of Texas Medical Center on November 5, 2012. Prior to that, he was professor and chairman of the Department of Cardiothoracic Surgery at Stanford University School of Medicine, where he served as a member of the faculty since 1993. He served as director of the Stanford Cardiovascular Institute, of the Heart- Lung and Lung Transplantation Programs, and of the Cardiothoracic Transplantation Laboratory. Dr. Robbins is an internationally recognized cardiac surgeon who has focused his clinical efforts on acquired cardiac diseases with a special expertise in the surgical treatment of congestive heart failure. His research work includes the investigation of stem cells for cardiac regeneration, cardiac transplant allograft vasculopathy, bioengineered blood vessels, and automated vascular anastomotic devices. As the CEO of the largest medical complex in the world, he brings world class expertise from a senior leadership perspective for all of the areas covered by the 12 assessments.

Dr. Mark D. Smith

Mark D. Smith, M.D., is founder and former President and Chief Executive Officer of the California HealthCare Foundation, an independent philanthropy in Oakland California, dedicated to improving the health of the people of California, particularly the underserved. He chaired the IOM's Committee on the Learning Healthcare System, which produced the widely publicized 2012 report Best Care at Lower Cost.

Dr. Glenn D. Steele, Jr.

Glenn D. Steele, Jr., M.D., Ph.D., is Chairman of xG Health Solutions and immediate past President and Chief Executive Officer of Geisinger Health System. Under his leadership from 2001–2015, this vertically integrated health care system has risen to be one of the most cost-effective, high quality provider organizations in the country. Prior to Geisinger, he was at the University of Chicago, where he served as Richard T. Crane Professor in the Department of

Surgery, Vice President for Medical Affairs, and Dean of the Biological Sciences Division and the Pritzker School of Medicine. Prior to that, he was the William V. McDermott Professor of Surgery at Harvard Medical School, President and Chief Executive Officer of Deaconess Professional Practice Group and Chairman of the Department of Surgery at New England Deaconess Hospital. Widely recognized for his investigations into the treatment of primary and metastatic liver cancer and colorectal cancer surgery, Dr. Steele is past Chairman of the American Board of Surgery. He serves on the editorial board of numerous prominent medical journals. His investigations have focused on the cell biology of gastrointestinal cancer and pre-cancer. Most recently, he has concentrated on innovations in health care delivery and financing.

Dr. Beth Ann Swan

Beth Ann Swan, Ph.D., CRNP, FAAN, is Dean and Professor, Jefferson College of Nursing, Thomas Jefferson University. An acknowledged leader in nursing and ambulatory care, she has deep expertise and research experience in technology applications for practice-based research; client outcomes, especially symptom distress and functional status following ambulatory surgery; post-acute care coordination and transition management; and dissemination of evidence, based on accessibility and usability of web-based evidence resources.

Dr. Gail Wilensky (Panel Co-Chair)

Gail Wilensky, Ph.D., is an economist and senior fellow at Project HOPE, an international health foundation. She directed the Medicare and Medicaid programs from 1990–1992 and served in the White House as a senior health and welfare adviser to President GHW Bush. Dr. Wilensky currently serves as a trustee of the Combined Benefits Fund of the United Mine Workers of America and the National Opinion Research Center, is on the Board of Regents of the Uniformed Services University of the Health Sciences (USUHS), the Visiting Committee of the Harvard Medical School, and the Geisinger Health System Foundation. She recently served as president of the Defense Health Board, a Federal advisory to the Secretary of Defense, was a commissioner on the World Health Organization's Commission on the Social Determinants of Health, and co-chaired the Dept. of Defense Task Force on the Future of Military Health Care. She is an elected member of the Institute of Medicine and has served two terms on its governing council. She is a former chair of the board of directors of Academy Health, a former trustee of the American Heart Association and a current or former director of numerous other non-profit organizations.

Preface

Congress enacted and President Obama signed into law the Veterans Access, Choice, and Accountability Act of 2014 (Public Law 113-146) ("Veterans Choice Act"), as amended by the Department of Veterans Affairs (VA) Expiring Authorities Act of 2014 (Public Law 113-175), to improve access to timely, high-quality health care for Veterans. Under "Title II – Health Care Administrative Matters," Section 201 calls for an Independent Assessment of 12 areas of VA's health care delivery systems and management processes.

VA engaged the Institute of Medicine of the National Academies to prepare an assessment of access standards and engaged the Centers for Medicare & Medicaid Services (CMS) Alliance to Modernize Healthcare (CAMH)[1] to serve as the program integrator and as primary developer of the remaining 11 Veterans Choice Act independent assessments. CAMH subcontracted with Grant Thornton, McKinsey & Company, and the RAND Corporation to conduct 10 independent assessments as specified in Section 201, with MITRE conducting the 11th assessment. Drawing on the results of the 12 assessments, CAMH also produced the Integrated Report in this volume, which contains key findings and recommendations. CAMH is furnishing the complete set of reports to the Secretary of Veterans Affairs, the Committee on Veterans' Affairs of the Senate, the Committee on Veterans' Affairs of the House of Representatives, and the Commission on Care.

The research addressed in this report was conducted by the RAND Corporation, under a subcontract with The MITRE Corporation.

---

[1] The CMS Alliance to Modernize Healthcare (CAMH), sponsored by the Centers for Medicare & Medicaid Services (CMS), is a federally funded research and development center (FFRDC) operated by The MITRE Corporation, a not-for-profit company chartered to work in the public interest. For additional information, see the CMS Alliance to Modernize Healthcare (CAMH) website (http://www.mitre.org/centers/cms-alliances-to-modernize-healthcare/who-we-are/the-camh-difference).

The views, opinions, and/or findings contained in this report are those of RAND Corporation and should not be construed as an official government position, policy, or decision.

Executive Summary

This report presents findings from Assessment A (identified under Title II—Health Care Administrative Matters, Section 201 of the Veterans Choice Act). The assessment responds to language in the Veterans Choice Act of 2014, Title II—Health Care Administrative Matters, Section 201.A.1.a, mandating "an independent assessment of current and projected demographics and unique health care needs of the patient population served by the Department."

Study Purpose and Approach

Assessment A examines the demographic characteristics of the current and projected population of U.S. Veterans and patients of the VA health care system. In addition, the assessment examines the unique health care needs of the patient population currently served by VA, and it projects the health care needs of Veterans who might become patients in the future. We use the term *Veteran* to describe all Veterans, whether or not they use VA health care services, and the term *VA patients* to describe Veterans who received at least some health care from VA in the past year.

Assessment A addresses four overarching research questions:

- What are the demographic characteristics of the U.S. Veteran population and how are these projected to change between 2015 and 2024?
- To what extent do Veterans, including VA patients, rely on VA for their health care?
- What are the current health care needs of the Veteran population, including both VA patients and non-VA patients, and how do these compare with the needs of the non-Veteran population? How will the needs of Veterans in general and the VA patient population specifically evolve over time given current policies?
- How might the projected number of Veterans and VA patients change due to external forces or changes in VA policies?

To address the research questions, the Task A assessment team conducted a series of analytic activities: Using a cohort-based approach, we estimated the size and demographic composition of the Veteran population; using the projected number of Veterans as a baseline, we estimated future enrollment in the VA health care system, the future size of the VA patient population, and the share of health care services that current Veterans receive from VA; we combined several data sources to assess the unique health care needs of Veterans and VA patients compared with non-Veterans; we used a modeling approach to assess how the number of VA patients and their health conditions might evolve over time; and we conducted scenario testing to understand how VA policies and external factors might affect the size of the Veteran population and the number of VA patients.

Background

VA provides health care services to enrolled Veterans who seek care at VA facilities, or—in some cases—through contracted care purchased from the civilian sector. Eligibility for VA health care has evolved over time, and today's eligibility rules are rooted in the Veterans Health Care Eligibility Reform Act of 1996. The law mandated health care for service-connected health conditions and for Veterans with a service-connected disability rated at 50 percent or higher. The Secretary of Veterans Affairs has legal discretion over the provision of all other care, but VA must maintain specialized treatment and rehabilitation programs for spinal injuries, blindness, amputations, mental illness, and other serious service-connected health conditions.

In general, a Veteran must have served in the U.S. military for at least 24 months and received an honorable discharge to enroll for VA health care. Some exceptions are permitted; for example, Veterans serving less than 24 months may be eligible if they were medically retired from military service due to a service-connected condition. To implement the 1996 law, VA established a priority system for determining which groups of Veterans will be authorized for care within the authorized budget. This structure places Veterans in one of eight priority groups based on their service-connected disability rating, income, and other factors. A Veteran's priority group designation affects his or her eligibility to receive care through VA, as well as his or her cost-sharing requirements (that is, whether co-payments are required and, if so, how much). Currently, enrollment is limited to recent combat Veterans, Veterans with qualifying incomes, and Veterans with service-connected or other disabilities. Based on our analysis of VA administrative data, about 9 million Veterans (42 percent of all Veterans) were enrolled in 2014. Non-enrolled Veterans include a mix of Veterans who are ineligible to enroll and Veterans who are eligible to enroll but choose not to do so.

Use of VA health care depends on a number of factors, including the total number of Veterans in the population, Veterans' eligibility to enroll for services, Veterans' enrollment decisions when eligible, and Veterans' decisions to seek VA health care services when enrolled. Because many Veterans have access to health care through other sources, such as employer insurance or Medicare, not all will choose to enroll, and those who do enroll may choose not to use VA for all of their health care needs. In addition, both VA policy and factors external to VA can affect Veterans' use of services. For example, a policy change enabling higher-income Veterans to enroll could increase demand for VA services. Similarly, a future military conflict could increase the number of Veterans in the pipeline and affect their health care needs. In our analysis, we distinguish VA enrollees from VA patients; a VA patient is an enrollee who has used VA health care in the past year.

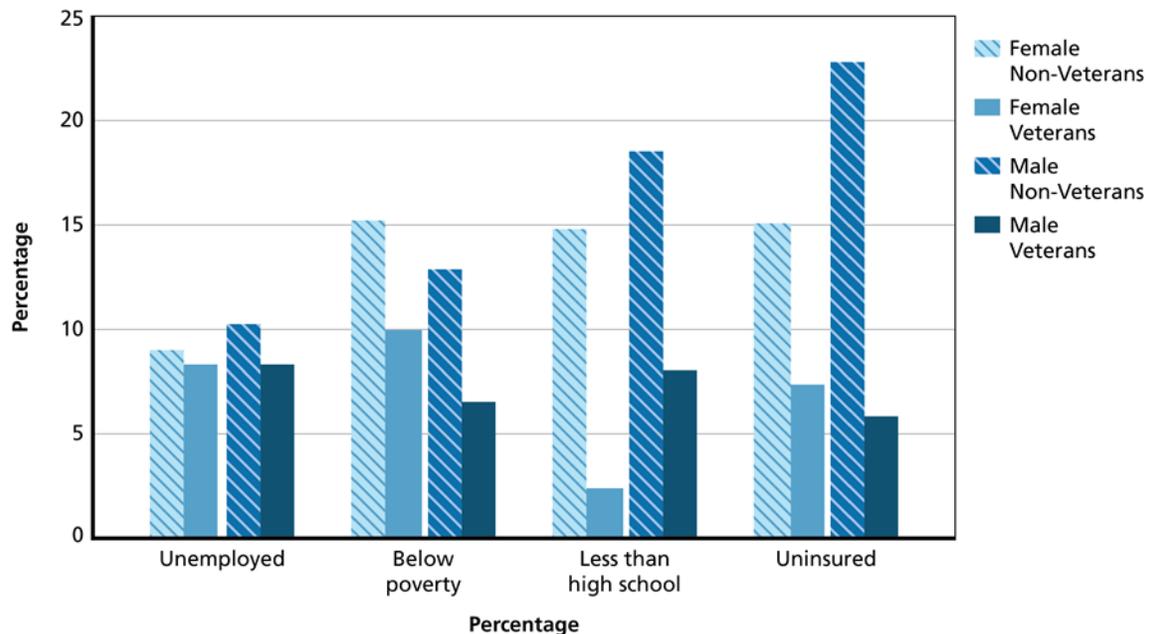
In this assessment, we used data from VA and from other federal sources, such as the U.S. Census Bureau, to estimate the total number of Veterans and VA patients, to project the size of these populations over time, and to estimate the health care needs of these populations. Our baseline estimates and projections assumed that VA policies and other factors that might affect Veterans' demand for services are constant, with adjustments for policy changes that have already been announced (such as the President's plan to reduce the size of the U.S. military). In scenario testing, we considered how uncertain future events, such as a future conflict or a

change in VA eligibility policy, might affect the size and health care needs of the Veteran and VA patient populations.

Key Findings

Current and Projected Demographic Trends in the Veteran Population

Today's Veterans generally enjoy favorable socioeconomic outcomes relative to their non-Veteran counterparts. Using data from the American Community Survey (ACS), we find that Veterans are less likely to be unemployed, less likely to be living below the poverty line, and more likely to have graduated from high school, on average, than non-Veterans (Figure ES-1). Veterans are also more likely than non-Veterans to have medical insurance; only 7 percent of female Veterans and 6 percent of male Veterans were uninsured during the 2009 to 2013 time period, according to the ACS. In contrast, 15 percent of female non-Veterans and 22 percent of male non-Veterans were uninsured during this time period. Rates of uninsurance among the Veteran population may be low in part because many Veterans have access to free insurance through VA. Insurance rates in the United States have increased since 2013, due to the implementation of the Patient Protection and Affordable Care Act (ACA) (Office of the Assistant Secretary for Planning and Evaluation, 2015a). We did not have data, however, that allowed us to compare post-ACA insurance rates between Veterans and non-Veterans.

Figure ES-1. Socioeconomic Characteristics of the Veteran and Non-Veteran Civilian Population, by Sex, 2009–2013


SOURCE: ACS, 2009–2013 five-year file.

Homelessness is declining among Veterans. Homelessness remains a significant problem among Veterans. Veterans are overrepresented in the U.S. adult homeless population: In 2010, Veterans accounted for approximately 10 percent of the adult population; however, they

represented a disproportionate share of the homeless adult (16 percent) and sheltered homeless adult (13 percent) populations (National Center for Veterans Analysis and Statistics, 2012b). Notwithstanding this, the rate of homelessness among Veterans has declined since 2010. According to the U.S. Department of Housing and Urban Development, there were 49,933 homeless Veterans in 2014, representing less than 0.25 percent of the total Veteran population. Between 2010 and 2014, the number of homeless Veterans declined by 33 percent (U.S. Department of Housing and Urban Development, 2014).

VA patients tend to be older and less socioeconomically well off than Veterans who do not rely on VA for care. Using data from the Medical Expenditure Panel Survey (MEPS), we are able to compare Veterans who use VA care with Veterans who do not use VA care (Table ES-1). VA patients are older and less well-off from a socioeconomic standpoint than Veterans who do not use VA for care. For example, 9 percent of VA patients have less than a high school education, compared with 6 percent of Veterans. VA patients' average household incomes are more than 20 percent lower than incomes for non-patient Veterans. VA patients are also far less likely to be employed than non-VA patients.[2] Partly, these differences are by design, because higher-income Veterans may not be eligible for VA services.

Table ES-1. Socioeconomic Characteristics of Veterans by VA Patient Status, 2006–2012

Characteristic	Veterans, VA Patients	Veterans, Non-VA Patients
Over age 65	52.2%	38.7%
Married	62.6%	68.0%
Less than high school education	9.1%	5.8%
Employed*	41.3%	62.8%
Average household income	$35,981	$45,278

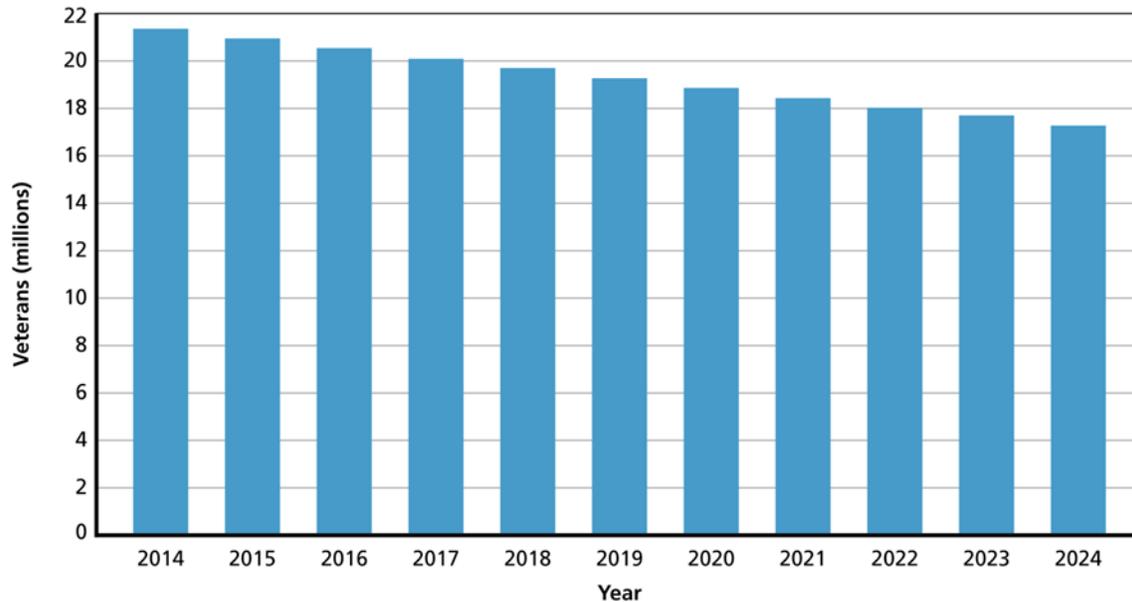
SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: Veterans, VA patients and Veterans, non-VA patients are mutually exclusive categories. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442.
* Non-employed individuals include both people who are unemployed and people who are out of the labor force, such as retirees.

We project that the population of U.S. Veterans will decrease by 19 percent over the next 10 years. The U.S. Veteran population has been decreasing for the past three decades, and this trend will continue. There were 27.5 million Veterans in the United States as of the 1990 Census; we estimate that there were 21.6 million Veterans in 2014. Over the next 10 years, our projections, drawing on VA, U.S. Census, and U.S. Department of Defense (DoD) data, showed that the Veteran population will decline to 17.5 million, a decrease of 19 percent relative to

---

[2] The remaining 37.2 percent of non-VA patients and 58.7 percent of VA patients who are not employed include both unemployed individuals and people who are out of the labor force because, for example, they are retired or disabled and unable to work.

2014 levels (Figure ES-2). Given the strong preexisting trends and the President's ongoing drawdown in the size of the active duty military population (Hagel, 2014; Parrish, 2011; Office of the Under Secretary of Defense [Comptroller], 2015), the reduction in the size of the Veteran population is inevitable, absent a major policy change to increase the size of the military (for example, if an unanticipated large-scale conflict were to materialize).

Figure ES-2. The Number of U.S. Veterans Will Decline by 19 Percent by 2024


SOURCE: RAND analysis of VA, DoD, and Census data.

Geographic distribution of Veterans will shift slightly. We estimate that, geographically, the Veteran population will become more concentrated in urban areas, and the relative proportion of the Veteran population in the Ohio River Valley region will diminish.

There will be modest changes in the demographic mix, by sex and race/ethnicity. Currently, Veterans are more likely than non-Veterans to be male, and are on average much older. We estimate that approximately 92 percent of the Veteran population was male in 2014. We also estimate that 75 percent of Veterans were age 55 or older, compared with only 34 percent of the non-Veteran population. By 2024, this will shift somewhat: The proportion of female Veterans will increase 3 percentage points, from 8 to 11 percent, by 2024, and the share of non-Hispanic white males will decrease from 80 to 74 percent over the same period. Mean age will increase slightly; the population will have a higher proportion of both older and younger Veterans.

These projections are based on historic separation rates, the anticipated decrease in military end-strength over the next several years, and an assumption that there are no significant new conflicts during the projection period.

Enrollment and Reliance on VA Health Care

The number of Veterans receiving VA health care is projected to level off over the next 10 years. While the Veteran population is projected to decline by 19 percent over the next 10 years, the number of VA patients is projected to increase until 2019. Use of VA health care has increased across all demographic groups since 2005, and the fraction of Veterans under age 35 who are VA patients has increased threefold. The growth of VA use by Veterans may be related to outreach efforts on the part of VA, policies that have expanded the list of conditions granting presumptive eligibility for VA services, and streamlined enrollment processes. Continued increases in the rates of VA use are expected to slow the decline in the number of VA patients. Nevertheless, in years beyond 2019, VA may begin to experience slight declines in the volume of patients. Because VA will be coming off a period of more than a decade of expanded use, careful monitoring and new policies may be necessary to address the leveling-off and possible reduction in demand for services that could occur after 2019.

Health care planning for VA is complicated by the fact that most Veterans have more than one possible source of health coverage. The extent to which Veterans use VA care as opposed to care from other sources is captured in the concept of *reliance,* by which we mean the fraction of Veterans' total care that is provided by or paid for by VA. Reliance on VA versus other sources of care varies by type of care, but it averages below 50 percent for many routine services. Across all types of care, Veterans under age 30 are the most reliant on VA and those over age 65 are least reliant.

Both VA policy, such as policies to enhance Veterans' access to VA services, and external trends, such as the cost and availability of private health insurance, can affect Veterans' reliance on VA. However, VA has limited visibility into patients' reliance. While VA has access to data on care obtained at VA facilities, it is difficult to track how much care Veterans consume outside of the VA system—for example, through private health insurance. Yet understanding reliance is critical for planning, because shifts in reliance can affect the total amount of care that Veterans obtain from VA facilities.

We analyzed reliance using data from MEPS and compared these estimates with reliance estimates used in VA's Enrollee Health Care Projection Model (EHCPM). MEPS is a survey of health care utilization and spending conducted by the Agency for Healthcare Research and Quality (AHRQ). The EHCPM is a forecasting model sponsored by VA, which relies on VA survey data, Medicare claims data, and proprietary data from the actuarial firm Milliman.

Using MEPS data, we found that younger Veterans, lower-income Veterans, Veterans in rural areas, Veterans without other access to health insurance coverage, and Veterans with poorer self-reported health status rely more than other Veterans on VA. However, the estimated share of care obtained through VA is generally lower in the MEPS estimates than in the EHCPM estimates. For example, MEPS indicates that VA patients obtain 30 percent of their prescription drugs through VA, compared with ECHPM's estimate that enrollees obtain 66 percent of their prescriptions from VA. Because the EHCPM estimates are in part based on proprietary methods, we were unable to ascertain fully the reasons for these differences. However, a general conclusion is that VA might benefit from validating current reliance estimates and investing in survey approaches to better understand Veterans' total health care needs.

Unique Health Care Needs of Veterans and VA Patients

To identify the unique health care needs of Veterans and the VA patient population,[3] we first compared the prevalence of key health conditions among the current Veteran population with those among the non-Veteran population. We then compared the prevalence of key health conditions among VA patients with those among Veterans who do not use VA health care and analyzed which characteristics (including the presence of particular health conditions) were associated with receiving care at VA facilities. Our analysis relied on MEPS, which collects information on all care received, regardless of payer, and information on Veteran status and use of VA services. With MEPS data, we can analyze all of a Veterans' diagnosed health conditions, regardless of whether the Veteran used VA health services. We can also use MEPS data to compare Veterans with non-Veterans. While the numbers reported in this summary are from MEPS, we also present in the body of the report findings from analysis of VA administrative data on patient encounters.

We examined both unadjusted prevalence rates of these health conditions and adjusted prevalence rates, which accounted for key demographic characteristics, such as age and sex. Both rates provide unique information with relevance to policy issues.

Unadjusted prevalence rates provide a snapshot of the overall Veteran population and enable us to compare how Veterans and VA patients may differ from civilians in terms of their health care needs. Unadjusted rates, however, do not account for the fact that Veterans are typically older and more likely to be male than civilians. Nevertheless, these numbers are useful for planning purposes. For example, the fact that Veterans have a much higher rate of diabetes than non-Veterans is useful for determining the types of providers and services that Veterans need, even if most of the difference between Veterans and non-Veterans can be explained by factors such as age and sex.

Adjusted prevalence rates help us understand how Veterans' and VA patients' health care needs may differ from the needs of demographically similar non-Veterans. As a result, these comparisons inform our understanding of how the experience of being a Veteran affects health. However, because they already account for demographic differences, without careful interpretation, the adjusted prevalence rates may appear to understate key differences in health care needs between Veterans and non-Veterans at the population level.

We also projected the prevalence of the health conditions of Veterans and VA patients forward over the next 10 years, accounting for predicted changes in their demographic composition and their service experiences.

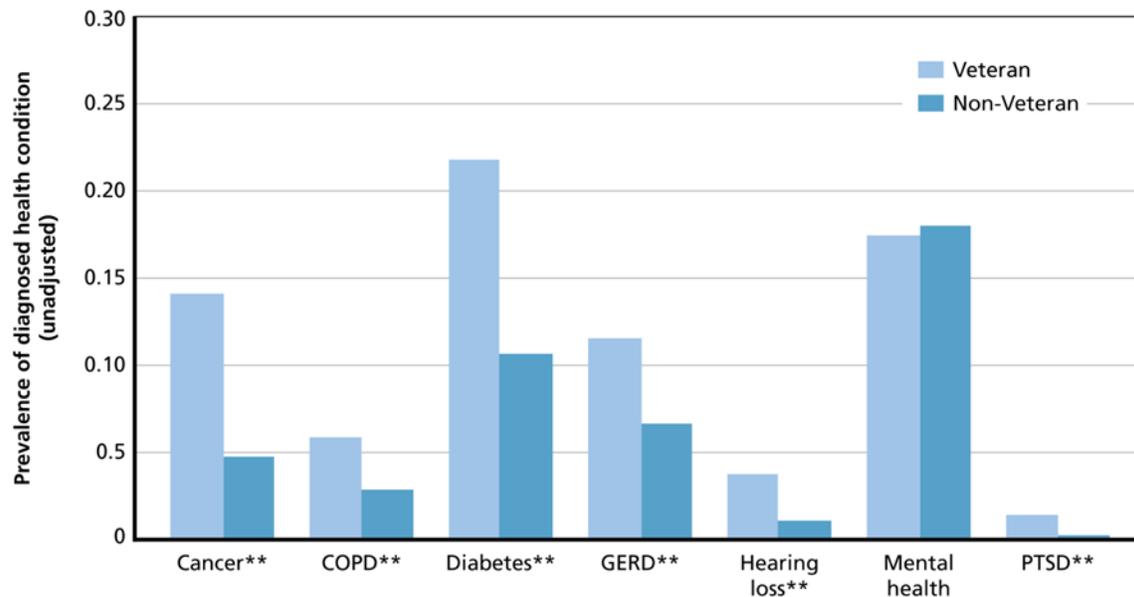
Veterans have a higher unadjusted prevalence of diagnosed health conditions than non-Veterans. The diagnosed prevalence of many common chronic health conditions, unadjusted for differences in demographic characteristics, is higher among Veterans than non-Veterans.

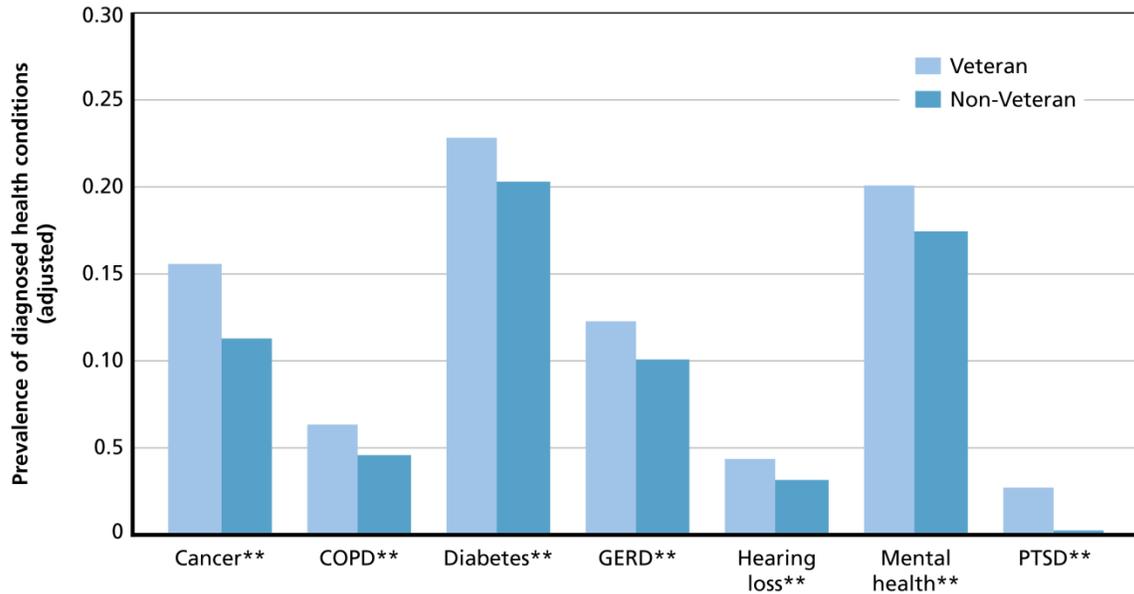
---

[3] We define the *unique* health care needs of Veterans as those that disproportionately affect Veterans relative to non-Veterans. These include both service-connected conditions, such as posttraumatic stress disorder (PTSD), and other conditions that are more prevalent among Veterans than non-Veterans, including diabetes and cancer.

For example, the prevalence of diabetes and gastroesophageal reflux disease (GERD) disorders among Veterans is substantially higher than for non-Veterans (Figure ES-3). Veterans are more likely than non-Veterans to be diagnosed with cancer, hearing loss, and PTSD. Mental health conditions, generally, are equally prevalent in the Veteran and non-Veteran populations. Because Veterans are more likely to have insurance than non-Veterans, some of these differences could reflect that Veterans are more likely to receive diagnoses than non-Veterans. Nevertheless, understanding differences in diagnosed conditions sheds light on differences in conditions that Veterans and non-Veterans are being treated for under existing policies. As such, these analyses inform our understanding of whether Veteran providers are likely to treat a different mix of conditions than civilian providers. Our analyses suggested that VA providers are likely to be treating a sicker population with more chronic conditions, such as cancer, diabetes, and chronic obstructive pulmonary disease (COPD), than the population expected by civilian providers.

Figure ES-3. Veterans Have Higher Diagnosed Prevalence of Several Key Health Conditions (Unadjusted Prevalence)



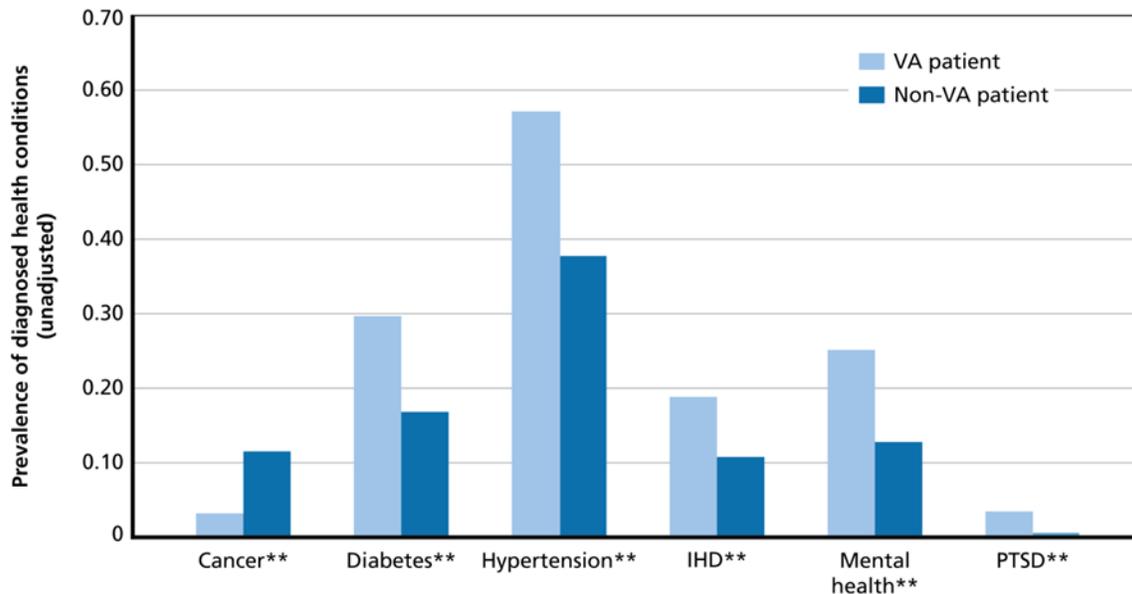


SOURCE: MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225 and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. Cancer includes any malignancy, and Mental Health includes any mental health condition.

Veterans also have a higher adjusted prevalence of key health conditions than non-Veterans. For some conditions, adjusting for demographic characteristics substantially reduces the difference in prevalence rates between Veterans and non-Veterans. For example, Veterans are twice as likely to have diabetes as non-Veterans in the unadjusted model, but after adjusting for demographic characteristics, the prevalence rate among Veterans is only 13 percent higher. In the adjusted model, Veterans are more likely to have mental health conditions than non-Veterans, while differences were not statistically significant in the unadjusted model. Even though fewer than 5 percent of Veterans are diagnosed with PTSD, it is even rarer in the non-

Veteran population. After controlling for age and other factors (Figure ES-4), Veterans are 13.5 times more likely than non-Veterans to be diagnosed with PTSD.

Figure ES-4. Veterans Have a Higher Prevalence of Several Key Health Conditions (Adjusted Prevalence)



SOURCE: MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. Cancer includes any malignancy, and Mental Health includes any mental health condition.

VA patients are typically less healthy than Veterans who do not use VA health care.
Compared with Veterans seen by private health care providers, Veterans who received treatment from VA had higher rates of cancer, diabetes, hypertension, PTSD, ischemic heart disease (IHD), and other conditions (Figure ES-5). These differences reflect VA patients' older age, and also reflect the eligibility criteria for enrolling in VA care, which depend in part on health status. Among VA patients, the unadjusted prevalence of common chronic conditions (e.g., diabetes, cancer) is 51 to 96 percent higher for VA patients relative to Veterans who do not use VA care; however, rates of PTSD are several orders of magnitude higher among VA patients relative to non-patients. Adjusting for demographic characteristics slightly reduces differences in prevalence rates between patients and non-patients (results shown in Section 5).

**Figure ES-5. VA Patients Have a Higher Prevalence of Several Key Health Conditions
(Unadjusted Prevalence)**

SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value <
0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,438. Sample sizes may be smaller for some
conditions due to missing values. Cancer includes any malignancy, and Mental Health includes any mental health condition.

According to the MEPS data in Figure ES-5, about 25 percent of all patients who accessed care
at VA had a mental health condition, and almost 4 percent had PTSD.[4] Rates of PTSD are
substantially higher among Veterans under age 35 (see Section 5). When combined with the
otherwise rare conditions related to combat—amputation, traumatic brain injury (TBI),
blindness, and severe burns—and the vulnerable circumstances of some patients, VA handles a
patient mix that differs from what community providers typically see.

**The prevalence of many common conditions is projected to increase among Veterans over
the next 10 years.** We estimate that aging in the Veteran population will lead to increases in
the prevalence of several common health conditions among Veterans over the next 10 years.
Figure ES-6 shows projected unadjusted prevalence for hypertension, diabetes, IHD, and mental
health conditions; in Section 5, we report similar charts for a more extensive set of conditions.
Among all Veterans, we estimate that the prevalence rates for diabetes and hypertension will
increase by about 12 and 8 percent, respectively, between 2015 and 2024. However, while
aging will tend to increase the prevalence of IHD, we estimated that prevalence rates for IHD
will decline during 2015–2024. This finding is consistent with long-standing trends toward

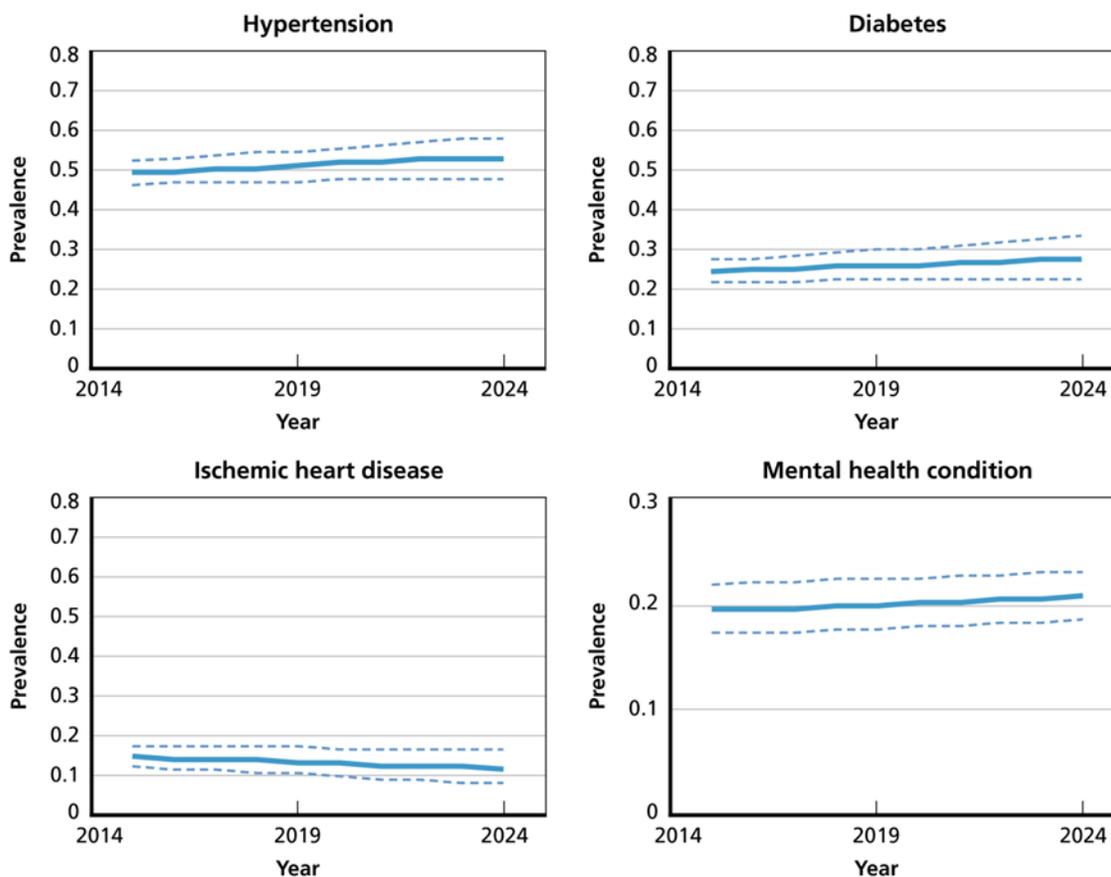
---

[4] As shown in more detail in Section 5, PTSD prevalence rates for VA patients are higher in the VA administrative
encounter data than in the MEPS data. The higher prevalence in the encounter data could reflect that these data
are more recent than MEPS, especially because we pool six years of data (2006–2012) in our MEPS analysis. In
addition, MEPS data could be biased downward if people are reluctant to report mental health conditions in
surveys, while VA encounter data could be biased upward if some encounters reflect "rule-out" diagnoses.

---

decreasing prevalence of acute coronary syndrome across all age groups in the U.S. population (Krumholz, Normand, & Wang, 2014; Talbott et al., 2013). However, this decline largely represents an extrapolation of recent declines in the prevalence of IHD noted in MEPS. The relatively large confidence bands suggest that the trend is uncertain and actual prevalence may not decline as sharply. Mental health conditions increase moderately over time, with prevalence rates rising by about 6.8 percent.

Figure ES-6 reports prevalence rates among all Veterans, which we estimated using a combination of data sources, including MEPS and MHS data, on service members who recently converted from active duty to Veteran status. In Section 5, we provide more detail on the analytic approach that we used to generate these estimates, and present additional results for VA patients (as opposed to all Veterans). In general, prevalence rates among VA patients increase somewhat more than prevalence rates for all Veterans. As a result, the gap in prevalence rates between VA patients and Veterans who do not use VA health care is projected to increase over time.

Figure ES-6. Projected Unadjusted Prevalence of Selected Health Conditions Among Veterans (2015–2024)


SOURCE: RAND analysis of VA, DoD, and Census data (2005–2014, Section 3), and MEPS (2006–2012).
NOTES: Solid lines indicate the projected prevalence for each health condition, which accounts for the changes in the composition of the VA patient populations by age, sex, race/ethnicity, Census region, and metropolitan statistical area (MSA).

The dashed lines indicate upper and lower bounds for the projected prevalence rates. (See Appendix C.1.5 for methodological details.)

Scenarios

We examined five scenarios, based on hypothetical future changes to VA policy or to the environment surrounding VA health care.

Scenario 1: Broader VA eligibility. Higher-income Veterans without disabilities are currently ineligible to enroll for VA coverage or to receive care at VA. Expanding eligibility to currently excluded groups could lead to more than 4.8 million newly eligible Veterans, and as many as 2.1 million new VA patients, amounting to a 35-percent increase in the size of VA's patient population.

Scenario 2: Including hypertension presumptively as a service-connected condition for Vietnam Veterans. According to the Institute of Medicine of the National Academies (IOM), there is increasingly solid evidence that hypertension among Vietnam-era Veterans is related to service in the Vietnam Theater of Operations. As yet, VA has not added hypertension to the list of presumptive conditions for Vietnam-era Veterans. If hypertension were included, we estimate that this would translate into 363,000 new VA patients, an increase of 6.4 percent in VA's total patient population.

Scenario 3: Hypothetical future conflict. How would demand for VA health care services be affected by future military conflict? In examining 36 possible scenarios, we found that the vast majority of them project between 500,000 and 925,000 new VA patients by 2024. However, most low-conflict scenarios anticipate 500,000 and 600,000 new patients, while most high-conflict scenarios predict between 750,000 and 925,000. This suggests that even moderate levels of deployment could substantially increase the size of the incoming cohort of VA patients. In fact, our projections suggest that, for every new patient that would have entered the VA system in more-peaceful times, approximately 1.5 new patients will enter the VA system following a major conflict. However, previous cohorts, especially the Vietnam cohort, were much larger than recent cohorts, so the difference will be small relative to the entire VA patient population.

Scenario 4: Expanding access to VA care by extending the Veterans Choice Act or by other means. Surveys have shown that 1.8 million Veterans reported not using VA care due at least in part to access barriers. We estimate that if these barriers were removed, at most an additional 235,000 Veterans per year might use VA.

Scenario 5: Effects of the ACA. Policy changes associated with the ACA could have conflicting effects on Veterans' use of VA health care. The individual mandate, which requires most individuals to obtain health insurance coverage, could increase Veterans' propensity to enroll in the VA system. However, ACA's coverage expansions, which include expanded Medicaid eligibility and subsidies to buy individual market insurance, could cause some current enrollees to use fewer VA services. Our analysis found that the net impact of ACA coverage expansions on the number of VA patients is relatively modest: We estimate 98,000 fewer VA patients under base assumptions, although other plausible assumptions result in increases in VA patient counts.

Conclusions and Recommendations

Overall Conclusions

The number of Veterans has been declining for three decades, and our analysis of the Veteran population over the next 10 years suggests that this trend will continue. The total number of Veterans is expected to decrease by 19 percent between 2014 and 2024. The median age of the population will continue to increase, and Veterans are projected to become more geographically concentrated over this period.

Veterans are more likely than non-Veterans to be diagnosed with health conditions, including those that are chronic and in some cases linked to service in the military. Although some of these differences may be explained by the age and sex characteristics of Veterans compared with non-Veterans, differences remain after these characteristics are taken into account. The higher adjusted prevalence rates may be related to the challenges of serving in the military and in combat.

Among all Veterans, those who receive at least some of their health care from VA are generally more likely than Veterans who do not use VA health care to be diagnosed with many of the conditions we examined in this assessment. This result may be related to the fact that eligibility to receive VA services is based, in part, on Veterans' disability status and presence of service-connected conditions.

Assessing trends in Veterans' health care needs is complicated, because assessing the need or demand for health care requires an understanding of the extent to which Veterans rely on VA to meet those needs. During the past three decades, the number of Veterans has decreased while the number of VA patients has increased. This is due in part to an increase in the number of Veterans who have been rated for service-connected disabilities, as well as policy changes that made more Veterans eligible for VA health care benefits (due to presumptive eligibility), that made it easier for Veterans to apply for benefits, and that gave the benefit of the doubt to Veterans in cases where there was uncertainty. Looking to the future, our patient projection models suggest that the number of VA patients will continue to increase through 2019, but could level off or decline in subsequent years.

In addition to VA policies, external policies (such as the ACA) and other trends (such as the cost of civilian health care) may influence the way Veterans interact with VA's health care system. Our analysis of five potential future scenarios illustrated the extent to which policy may affect the projected number of Veterans and VA patients. Among them, expanding eligibility rules to include higher-income Veterans, entering future conflicts, and improving access to VA health care generated the largest increases in new Veterans and VA patients.

Finally, VA data systems and U.S. data collection efforts more broadly have significant limitations that hinder planners' ability to assess how demand for VA services might change over time. For example, there has not been a full accounting of the U.S. Veteran population since the 2000 Census. In addition, current VA data collection systems do not assess detailed information on Veterans' health care conditions and health care utilization patterns. Important data gaps include that data are often completely unavailable for Veterans who are not currently

eligible or enrolled in VA health programs. Even among those who use VA care regularly, VA has detailed information only on care paid for or provided by VA, or paid for by the federal Medicare program. Additional data collection would be needed to fully understand Veterans' total health care needs, including use of care currently provided by the civilian sector. Understanding these gaps is important because shifts in patient reliance and changes in eligibility rules could cause more Veterans to seek care at VA, and could change the mix of care sought from VA versus civilian providers.

Recommendations for Consideration

Prepare for a Changing Veteran Landscape

The number of VA patients has been increasing since 2005, despite the three-decades-long decline in the size of the Veteran population. We estimate that this increase will continue through 2019. However, in 2020 and beyond, it is likely that the size of the VA patient population will level off or even decrease. Total demand for VA services during this time period will be heavily influenced by utilization patterns among patients; if the health care needs of the population are significant or the cost of outside options is high, patients may use more care than they have in previous years. Nonetheless, there is a possibility that demand for services will level off or decline as the continued growth in the patient population slows or even reverses. The likely short-term growth in demand, followed by a leveling-off or decline in the next decade, may make it difficult to ensure that the size of the VA health system is tailored to fully meet the needs of the population in the near term without becoming inefficiently large in the long run. Increasing the use of care purchased from the civilian sector may enable VA to meet short-run increases in demand without requiring costly investment in facilities, infrastructure, and personnel that could become less needed in the future.

Improve Tracking of Some Veteran Populations

Because the 2010 Census did not capture information on Veteran status, there has not been a full-scale accounting of the U.S. Veteran population since 2000. As a result, VA must estimate the size of the Veteran population using data from more than 15 years ago, coupled with smaller surveys and information on personnel losses from DoD. While ACS provides information on a sample of Veterans (1,197,923 Veterans in the 2009–2013 sample), this is not a full accounting of the Veteran population. An updated census of the Veteran population would enable a definitive count of all Veterans, while also helping to refine sampling procedures for the yearly surveys of samples of the population. Given that the events of September 11, 2001, set off prolonged U.S. engagement in oversees conflict and changed DoD accession and personnel retention policies that affect the flow of service members from active duty to Veteran status, it seems that the nation is overdue for an updated census of the Veteran population. We recommend asking about Veteran status in the 2020 Census.

In addition, little is currently known about how the utilization patterns and health care needs of Veterans from the conflicts in Afghanistan and Iraq will evolve over time. Yet, Afghanistan and Iraq Veterans are more likely to have service-connected disabilities than other Veterans and are automatically eligible for VA health care for five years after leaving the military. Historically, Veterans have relied less on VA health care as they age, gain access to other health insurance

(e.g., through an employer), and start families. However, it is not clear the extent to which these patterns will hold for newer Veterans who have different exposures and enhanced eligibility relative to previous cohorts. Closely monitoring this population may help VA planners to prepare as this population ages and their health care needs and utilization patterns shift.

Anticipate Potential Shifts in the Geographic Distribution of Veterans, and Align VA Facilities and Services to Meet These Needs

While our estimates suggest that the geographic distribution of Veterans will remain relatively stable over time, there may be several opportunities to streamline or shift VA resources to ensure adequate capacity in all parts of the country. Given projected declines in the size of the Veteran population living in the Ohio River Valley and upper Midwest, it may be possible to consolidate relatively proximal VA facilities in those regions. At the same time, some areas of projected Veteran population growth—including Montana, Wyoming, and Colorado—are not currently well covered by VA facilities. While the absolute size of the Veteran population in these areas will remain small, there may be opportunities to use telehealth and community-based outpatient clinic (CBOC) services to meet Veterans' needs in these areas. There may be a more pressing need to expand VA coverage in the Southwest, where Veteran Affairs Medical Centers (VAMCs) are currently widely spaced, and where growth in the Veteran population is expected to be significant. Finally, we estimate that the Veteran population under age 35 will increase in the regions around Los Angeles; Dallas; Washington, D.C.; and northern New Jersey by 2024. VA facilities in these areas might monitor growth in utilization among younger Veterans to ensure that they are able to meet the needs of this group.

Improve Collection of Data on Veteran Health Care Utilization and Reliance

Fully understanding the needs of the patient population served by VA will require data that do not currently exist. This data would capture information on all sources of health care that are used by an individual—including when and where care is delivered, what diagnoses are recorded and procedures performed, and who pays for the services—as well as what needs for care are unmet, and why. The data would also require a large enough sample of Veterans to ensure that it is representative of the population, and to allow VA to track the prevalence of relatively rare service-connected conditions. Creating these data would enable an analysis of the extent to which Veterans currently rely on VA for health care, as well as how that reliance may change as a result of internal VA policies or external factors. It would also provide insight into where VA succeeds in meeting the health care needs of its patient population and what types of obstacles exist in delivering needed care. In addition, by collecting information on Veterans who are not currently patients, the data would enable VA to better plan for changes in the demand for services that might occur if VA eligibility rules changed, or if additional Veterans chose to enroll.

Current surveys of Veterans do not capture comprehensive information on health care use, particularly among Veterans who are not currently eligible for or enrolled in the VA system. While MEPS contains information on all the care that respondents receive regardless of payer, the survey contains only a small sample of Veterans, and this sample may not be adequately representative of the population. VA might consider fielding a comprehensive survey of all

---

Veterans, aimed at assessing their total health care use patterns, including use of non-VA care. Such a survey could be modeled on the MEPS Household Component (MEPS-HC), which collects utilization data across all sources of care for the general population. Potentially, VA could work with AHRQ (the organization that fields MEPS-HC) to include a more robust sample of Veterans in its survey.

Incorporate Separation Patterns and Health Care Needs of Current Service Members into Projections

In this assessment, we incorporated data on current service members—who will become Veterans in the future—in several of our analyses, including (1) counts of service member separations in our demographic analysis to augment Census data of Veterans from 2000, (2) diagnosed health conditions of separating service members who received care through the Military Health System (MHS), and (3) estimated number of service members who would separate and become Veterans in the case of a hypothetical future conflict.

At present, VA does not have access to DoD MHS encounter data. Such data could enable VA planners to analyze health care needs among current active duty service personnel who may become Veterans in the future. For this study, we utilized MHS data from 2008 to 2014 to explore whether current service members (future Veterans) have different health care needs from current Veterans. We estimate that service members are much more likely than current Veterans to have a diagnosed musculoskeletal condition or asthma at the time of separation from service. On the other hand, the prevalence of mental health conditions is higher in the existing Veteran population than among separating service members. This result may reflect a disincentive to seek care for mental health conditions while serving in the military. To the extent that individuals who separate from the military and become Veterans during the 2015–2024 projection window have different health care needs from the patients currently being served by VA, adding MHS data is critical for projecting the needs that VA must meet in the future.

Develop an Analytic Framework to Perform Scenario Testing

Our analysis of five future scenarios highlights the importance of developing methods and models that can respond quickly and agilely to policy changes. While some of the policy changes we considered resulted in modest changes in number of new Veterans and new VA patients, others estimated as many as hundreds of thousands of new Veterans and patients. The VA Office of the Actuary (OACT) has a Veteran Healthcare Scenario Model, which is able to estimate, for instance, how changes in demographic characteristics or economic conditions (such as employment or income) may affect demand for VA services and related costs. Expanding this model to include such events as changes in the civilian health sector, unanticipated changes in perceptions about health care quality, and groundbreaking new technologies, to name a few, will enable VA to address the types of uncertainties that current models may not address. Having methods in place to estimate the effects of these types of changes on Veteran demand for health care services will improve VA's efforts to meet the health care needs of its patient population.

1 Introduction

1.1 Background

The Veterans Access, Choice, and Accountability Act of 2014 ("Veterans Choice Act") was signed into law on August 7, 2014. In addition to expanding the criteria through which Veterans can access civilian providers for their health care, the legislation called for an independent assessment of the VA health care system across a broad array of topics related to the delivery of health care services to Veterans in VA-owned and -operated facilities, as well as those under contract to VA.

In September 2014, the CMS Alliance to Modernize Healthcare (CAMH)—the MITRE Corporation's federally funded research and development center—entered into a contract with VA to serve as the overall integrator for the independent assessment. MITRE subcontracted with the RAND Corporation to conduct three of the 11 specific assessment tasks (Assessments A, B, and C) and to furnish reports on the findings and recommendations from these assessments for inclusion in an integrated report to VA and Congress.

This report presents findings from Assessment A (identified under Title II—Health Care Administrative Matters, Section 201 of the Veterans Choice Act), which examined the current and projected demographics and unique health care needs of Veterans and the patient population served by VA. In this report, we use the term "Veteran" to describe all Veterans, whether or not they use VA health services, and "VA patient" to describe an individual who received at least some health care from VA in the previous year.

The Veterans Choice Act language requires that Assessment A shall address "current and projected demographics and unique health care needs of the patient population served by the Department." Our team has interpreted this language to require an independent analysis of the current characteristics and unique health care needs of the Veteran population and VA patients, and estimates of how the characteristics and needs of these populations will evolve over time. To generate these estimates, we have compiled data from VA administrative files, DoD administrative files, surveys conducted by the U.S. Census Bureau and other federal agencies, and surveys conducted by VA to develop a comprehensive picture of U.S. Veterans, VA patients, and the demographic characteristics and health care needs of these populations. We have then used established statistical methods to project these characteristics and needs forward over time. Finally, we have considered the extent to which uncertain future events, including changes to VA policy, possible future military conflicts, and other external factors, might affect the size and characteristics of the Veteran population overall and of VA patients specifically.

1.2 Motivation

U.S. Veterans represent a special population of individuals who have served their country and may have faced extraordinary health risks during deployment to combat areas. Part of the promise America makes to its armed forces is to provide for their health care needs during their service and afterward, when it is the mission of VA to meet Veterans' needs. Because many

Veterans have served overseas missions, including combat, Veterans are a clinically complex and vulnerable population. Meeting the needs of this population requires a clear understanding of Veterans' distinctive characteristics in comparison with non-Veterans, in terms of both their demographic and health characteristics, and how these are likely to evolve.

The Veterans Choice Act and its congressionally mandated assessments were further motivated by challenges faced by VA patients in recent years, including long wait times to receive services, poor patient outcomes, and a million-person backlog among Veterans waiting for disability claims to be evaluated. While Assessment A does not directly address these specific challenges, understanding the size, demographic composition, and health care needs of the population eligible for VA services is critically important to ensure that VA has the capacity to meet Veterans' needs in the future.

1.3 Purpose

This report responds to the Veterans Choice Act requirement for an independent assessment of the demographics and health care needs of the Veteran population. Specifically, the assessment examines the demographic characteristics of the current and projected population of U.S. Veterans and VA patients. In addition, the assessment delineates the unique health care needs of the patient population currently served by VA, as well as the projected needs of Veterans who might become patients in the future. The findings of this assessment will inform future VA efforts to plan, budget, and staff, and, along with the findings from Assessment B (health care capabilities and resources of VA),[5] will highlight areas where assets do not meet current or projected needs.

This assessment addresses four overarching research questions:

- What were the demographic characteristics of the U.S. Veteran population in 2014 and how are these projected to change between 2015 and 2024?
- What are the current health care needs of the Veteran population, including both VA patients and non-VA patients, and how do these compare with the needs of the non-Veteran population? How will the needs of Veterans in general and the patient population specifically evolve over time given current policies?
- To what extent do Veterans rely on VA for their health care?
- How might external forces or changes to VA policy affect the characteristics of Veterans, their eligibility to use VA health care, and their health care needs over time?

Defining the "unique" health care needs of the VA population is challenging, because many common health conditions affecting Veterans also affect non-Veteran populations. Further, even though there are many combat-related conditions that are important to VA—such as amputations, burns, and TBIs—these conditions are not, strictly speaking, "unique" to Veterans; they can occur among civilians as well. We therefore define the unique health care needs of Veterans as those that disproportionately affect Veterans relative to non-Veterans.

---

[5] See Assessment B in this series, on VA health care resources and capabilities.

These include both service-connected conditions, such as PTSD, and other conditions that are more prevalent among Veterans than non-Veterans, including diabetes and cancer.

An additional challenge that we face in this analysis is that not all Veterans are currently eligible to receive care at VA, not all eligible Veterans opt to enroll for services, and not all enrollees receive all or even the majority of their care from VA. From a conceptual standpoint, estimates of the future VA patient population must account for the possibility that Veterans' enrollment and use patterns may change over time due to external factors, such as the cost of private health insurance. From a data standpoint, estimates must address the fact that the VA health system's data include only information on VA patients, and will not necessarily include comprehensive data on patients' total health care utilization and diagnoses. In Section 2, we provide a conceptual discussion of these issues. Much of the analyses reported in Sections 4 and 5 aim to understand differences between VA patients and non-patients and to determine the health care needs of these populations without relying solely on information reported in VA patient data.

1.4 Scope of the Analysis

We recognize that VA has developed several models, including the Veterans Population Projection Model (VetPop) and the EHCPM, that forecast the size and characteristics of the VA population and the health care utilization of VA patients. In keeping with Congress's desire for an independent assessment, we generate our own estimates of the Veteran and patient populations, without relying on existing VA models. However, our work is not meant to replace these models, which are extremely sophisticated tools that VA has spent years refining. Rather, our goal is to take a fresh look at population and patient projections, in some cases using new methodologies and data. The analyses presented here may be useful to VA planners when considering future updates or refinements to existing VA models.

As part of our analysis, we reviewed the methods used to develop VetPop and EHCPM, and we discuss these methods in the report. We do not, however, provide a systematic evaluation of the strengths and weaknesses of existing VA models. Our focus is on understanding the Veteran population rather than evaluating VA's current modeling approaches.

Our baseline estimates consider the Veteran population in 2014. To estimate trends over time, we have chosen a 10-year time frame, from 2015 through 2024. In selecting this period, we aimed to balance the need for a long-term understanding of how the Veteran and VA patient populations might evolve against the reality that predictive models become less reliable when forecasting far into the future. We settled on a 10-year projection window, which aligns with the time frame used by the Congressional Budget Office when scoring legislation.

Finally, it is worth noting that this analysis was conducted under constraints due to the short time frame allotted for conducting the assessments and the limited availability of data. The entire assessment was conducted in an eight-month time frame. Many of the VA and DoD data sources that we used in this analysis required special permissions that took months to obtain and further limited the time in which we could conduct analysis.

1.5 Organization of the Report

The rest of this report is organized as follows: Section 2 presents an overview of the Veteran population and the VA enrollment process. This section also provides an overview of our modeling approach and a brief description of methods. In Section 3, which responds to the congressional requirement to analyze Veterans' "current and projected" demographics, we discuss our model of the Veteran population, its demographic characteristics, and how the size and characteristics of this population might evolve over time. One key attribute we consider in analyzing demographics is where Veterans are geographically located, both now and in the future. Section 4 discusses Veterans' decisions to enroll in VA health care and reliance on VA when enrolled. Section 5 responds to the requirement to assess the "unique health care needs of the patient population served by the Department," and focuses on understanding the current needs of both Veterans and VA patients, and how these needs will evolve over time under current policy. In Section 6, we consider hypothetical future scenarios that might affect the size and composition of the Veteran population, Veterans' propensity to use VA health services, and the health care needs of future Veterans. This section builds on the analyses presented in Sections 3, 4, and 5 by recognizing the inherent uncertainty in attempting to predict future outcomes and providing alternative estimates of future trends. Section 7 presents the study's conclusions and recommendations.

2 Conceptual Framework

2.1 Introduction

While we present a more detailed summary of specific methods in subsequent sections and appendixes, this section focuses on our conceptual approach. Below, we briefly describe the distinction between a Veteran and a VA patient, and outline steps that a Veteran must take to enroll and begin using VA health care. In addition, we provide an overview of the approach we used to model how the population of Veterans, and correspondingly VA patients, might evolve over time. Finally, we discuss a framework for analyzing how patient needs may change in the future.

2.1.1 Definition of a Veteran and Eligibility to Use VA Health Care Services

A Veteran is defined by law as "a person who served in the active military, naval, or air service, and who was discharged or released there from under conditions other than dishonorable" (Enrollment—Provision of Hospital and Outpatient Care to Veterans, 2003). We estimate that there were 21.6 million Veterans in the U.S. population in 2014. However, there are additional eligibility requirements for enrolling in the VA health care system. Current eligibility rules for VA health care were established in the Veterans Health Care Eligibility Reform Act of 1996. The legislation revised Section 1710 in Title 38 to mandate health care for:

- Veterans with service-connected health conditions
- Veterans with a compensable service-connected disability or who received a disability discharge from the military
- Veterans unable to pay for their health care
- Certain other specific groups.

This mandate, however, is subject to the appropriated funding. For the first time, the 1996 legislation also gave VA discretionary authority to provide health care to all other Veterans "to the extent and in the amount provided in advance in appropriations Acts for such purposes." The Secretary of Veterans Affairs has legal discretion over the provision of all other care, but VA must maintain specialized treatment and rehabilitation programs for spinal injuries, blindness, amputations, mental illness, and other serious service-connected health conditions. Under current policy, all enrolled Veterans have access to VA's comprehensive health care benefits package, but a Veteran may also receive certain benefits (e.g., dental care) based upon his or her unique eligibility status (U.S. Department of Veterans Affairs, 2014c).

Consistent with the legal definition of a Veteran, eligibility for health care is limited to individuals who are former active duty service members, or current or former reservists or national guardsmen who (a) were called to active duty by a federal order, and (b) completed the full period of that active service. Veterans also must have served either 24 continuous months or the full period for which they were called to active duty. Exceptions to this minimum service duty requirement apply to Veterans who were discharged for a disability incurred or aggravated in the line of duty, discharged for a hardship or "early out," or served prior to

September 7, 1980 (U.S. Department of Veterans Affairs, 2015c). The VA website notes that there are numerous additional exceptions to the minimum duty requirements, which can be evaluated during the enrollment process. In Section 6, we estimate that 17.8 million (81 percent) of all individuals with any military service meet these basic enrollment criteria. However, as we discuss below, not all of these Veterans are currently eligible to enroll and use VA health care.

Under certain extenuating circumstances (for example, if a Veteran is rated permanently and totally disabled due to a service-connected disability, or if a Veteran dies while on active duty), a Veteran's family members may also be eligible for VA health benefits. However, VA health care for Veterans is prioritized over that for Veteran dependents.

2.1.2 Enrollment Priority Groups

VA uses Veterans' service-connected disability ratings, along with income and other factors, to assign Veterans to one of eight priority groups through its enrollment system (Congressional Budget Office, 2007, 2009). Priority groups are used to determine a Veteran's enrollment priority, a Veteran's access to certain additional health care benefits, and whether co-pays are required. The three highest priority groups (priority groups 1–3) are for Veterans with a service-connected disability rated at 10 percent or higher. Table 2-1 lists all of the current VA priority groups, including a brief description of each. Eligibility determinations and assignments to priority groups are made by the Health Eligibility Center in Atlanta, Georgia (U.S. Department of Veterans Affairs, 2015g).

Table 2-1. VA Priority Groups for Enrollment

Priority group	Description
1	• Service-connected disability 50% or more disabling • Veterans determined unemployable due to service-connected disabilities
2	• Service-connected disability 30% or 40% disabling
3	• Service-connected disability 10% or 20% disabling • Other: former prisoners of war (POW); Purple Heart medal awardees; Medal of Honor awardees; Veterans discharged for disability incurred during/aggregated by military service; other
4	• Catastrophically disabled (ability to complete activities of daily living is permanently compromised; Veterans require personal/mechanical assistance to leave home/bed or require constant assistance) • Recipients of VA aid/attendance or housebound benefits
5	• Low income: annual income below zip-code-based adjusted income limits; Veterans receiving VA pensions; Veterans eligible for Medicaid

Priority group	Description
6	• Service-connected disability 0%, compensable • Veterans with occupational exposures • Ionizing radiation from atmospheric testing, Hiroshima, or Nagasaki • Project 112/SHAD participants • Service in Vietnam (January 9, 1962–May 7, 1975) • Service in Persian Gulf War (August 2, 1990–November 11, 1998) • Service on active duty at Camp Lejeune for at least 30 days (August 1, 1953–December 31, 1987) • Service in theater of combat operations after November 11, 1998, and discharged after January 28, 2003
7	• Low income: gross household income below geographically adjusted income limits; agree to co-pays
8	• Veterans with gross household income above VA and the geographically adjusted income limits for their resident location and who agree to pay co-pays
Priority Group 8 Veterans Who Are Currently Eligible to Enroll for VA Health Care	
8a	• Veterans with noncompensable 0% service-connected disabilities who enrolled as of January 16, 2003, and who have remained enrolled since that date and/or placed in this subpriority due to changed eligibility status
8b	• Veterans with noncompensable 0% service-connected disabilities who enrolled on or after June 15, 2009, whose income exceeds the current VA or geographic income limits by 10% or less
8c	• Veterans without a service-connected disability who enrolled as of January 16, 2003, and who have remained enrolled since that date and/or placed in this subpriority due to changed eligibility status
8d	• Veterans without a service-connected disability who enrolled on or after June 15, 2009, whose income exceeds the current VA or geographic income limits by 10% or less
Priority Group 8 Veterans Who Are Not Currently Eligible to Enroll for VA Health Care	
8e	• Veterans with noncompensable 0% service-connected disabilities who do not meet the criteria for priority groups 8a–8d
8f	• Veterans without a service-connected disability who do not meeting the criteria for priority groups 8a–8d

SOURCE: U.S. Department of Veterans Affairs, 2015c.
NOTE: Veterans assigned to priority group 8 who do not meet the criteria listed in the table are currently ineligible to receive VA care.

In 2003, VA sought to improve access to services for higher-priority Veterans by restricting enrollment of higher-income Veterans without service-connected disabilities (Goldberg, 2015). In part, this policy was created because VA is funded through annual appropriations, and restricting enrollment helped to keep spending within VA's budget. The policy also was created to "recognize the higher obligation owed to Veterans requiring care for their service-connected disabilities, and to lower-income Veterans" (Enrollment—Provision of Hospital and Outpatient Care to Veterans, 2003). Based on this policy, VA continued to treat Veterans in all priority groups and treat new enrollees in priority groups 1–7, but suspended the enrollment of additional Veterans in priority group 8.

The most recent change in enrollment eligibility, in May 2009, relaxed the enrollment restrictions on Veterans in priority group 8 (U.S. Department of Veterans Affairs, 2009a). Under

the new policy, additional subpriorities were added for priority group 8 for Veterans whose income exceeded the current VA national means test or geographical means test income thresholds[6] by 10 percent or less (Expansion of Enrollment in the VA Health Care System, 2009). The new regulations went into effect in June 2009, and VA then began enrolling (for VA health care benefits) those Veterans who were eligible in subgroups 8a through 8d, while continuing to exclude Veterans in subgroups 8e and 8g (Congressional Budget Office, 2009). Of the 17.8 million who we estimate meet the basic eligibility criteria, 13 million (73 percent) are in priority groups 1 through 8d or in groups 8e and 8g but enrolled prior to the most recent eligibility change in 2009.

For many Veterans, enrollment eligibility hinges on income. Veterans whose incomes fall below the national income test, who are Medicaid eligible, or who receive a disability pension are classified into priority group 5, unless they qualify for a higher priority group based on service-connected conditions or other disabilities. In some cases, there is a geographic means test (GMT) that exceeds the national income threshold. Veterans whose income is above the national income threshold but below the geographic means threshold are classified in priority group 7. Those with higher incomes may qualify for priority groups 8a or 8d, if their incomes are within 10 percent of the relevant threshold (either the national income threshold or the GMT, whichever is binding). Both the national income threshold and the geographic means threshold vary depending on whether a Veteran has dependents.

Veterans who served in a combat theater after 1998 have automatic eligibility to enroll for up to five years after they leave the military.[7] These Veterans are placed in priority group 6 unless they qualify for a higher priority group (e.g., have a disability rating of 10 percent or higher or income below the threshold for priority group 5). Veterans with qualifying occupational exposures are also placed in priority group 6, unless they qualify for a higher priority group based on income or disabilities. A Veteran may apply for VA health care benefits at any time after separation (U.S. Department of Veterans Affairs, 2009b).

2.1.3 Use of VA Services Conditional on Enrollment

Once Veterans enroll and are deemed eligible to receive care, Veterans must make a choice about whether to use VA health care and how much care to consume. The majority of enrolled Veterans have access to other health care coverage, and approximately half of enrolled Veterans are also enrolled in Medicare or Medicaid (Congressional Budget Office, 2009; Goldberg, 2015). Enrolled Veterans receive the majority of their health care outside of VA (Goldberg, 2015). The term reliance refers to the fraction of a Veteran's total care that is provided by or paid for by VA. Based on the EHCPM, VA estimates that current VA patients have on average about 21 percent of their total physical medicine (that is, physical therapy and

---

[6] These thresholds are established by the Department of Housing and Urban Development.

[7] On February 12, 2015, the Clay Hunt Suicide Prevention for American Veterans Act provided a one-year window of enhanced enrollment for combat Veterans who were discharged or released from active service after January 1, 2009 and before January 1, 2011, who did not enroll within the original five-year window.

---

occupational therapy) visits with VA, 38 percent of their emergency room visits with VA, and 66 percent of their prescriptions from VA.

However, reliance rates can vary substantially based on Veterans' health care needs and underlying characteristics. Veterans enrolled in priority group 1 (those with a service-connected disability rated 50-percent or more disabling) and in priority group 4 (those with a nonservice-connected catastrophic disability) face the highest overall health care costs and rely on VA for a greater percentage of their medical care than other Veterans (Congressional Budget Office, 2009). In general, VA enrollees with private insurance are less likely to use VA care than other Veterans (Shen, Hendricks, Wang, Gardner, & Kazis, 2008). Veterans who utilize VA for all of their health care are more likely to be from disadvantaged (poor, less-educated, minority) groups (Nelson, Starkebaum, & Reiber, 2007). Among Veterans with Medicare, those Veterans who are disability-eligible for Medicare have more VA primary and specialty care visits than Veterans age-eligible for Medicare (Liu et al., 2012). The increased utilization of both primary and specialty care among disability-eligible Veterans with Medicare is likely due to greater health care need (Liu et al., 2012). Other factors, such as access constraints and perceived quality, may also affect Veterans' decisions to use care.

In fiscal year (FY) 2014, 6.2 million unique patients used VA health care services or received VA reimbursed treatment (Table 2-2). The majority of VA users were Veterans (5.9 million), and 4.6 million of these Veterans were in priority groups 1 through 6. The table focuses on Veterans who sought any care, regardless of how much care they obtained at VA.

Table 2-2. VA Health Care Users (FY 2014)

Type of VA Health Care User	FY14 Unique Patients
Priority Groups 1–6	4,612,915
Priority Groups 7–8	1,256,610
Priority Group Not Assigned	2,241
Veterans	**5,871,766**
Non-Veterans	308,805
Total Unique Patients	6,180,571

SOURCE: Authors' analysis of FY 2014 data from the Veterans Health Administration (VHA) Support Service Center.
NOTES: *Unique patients* are unique individuals who were treated by VA or received treatment paid for by VA; Non-Veterans include active duty military and reserve, family members of Veterans who qualify to enroll, VA employees receiving occupational health care, and so on.

Between 2000 and 2011, the number of Veterans seeking inpatient treatment increased by 131 percent, and the number of Veterans seeking outpatient care increased by 201 percent (National Center for Veterans Analysis and Statistics, 2011b). The number of Veterans seeking VA care continued to increase through 2012 (National Center for Veterans Analysis and Statistics, 2014e). These increases occurred despite a substantial decline in the size of the Veteran population. For example, the U.S. Census Bureau estimates that there were more than 26 million U.S. Veterans in 2000 (Richardson, 2003), compared with just under 22 million today

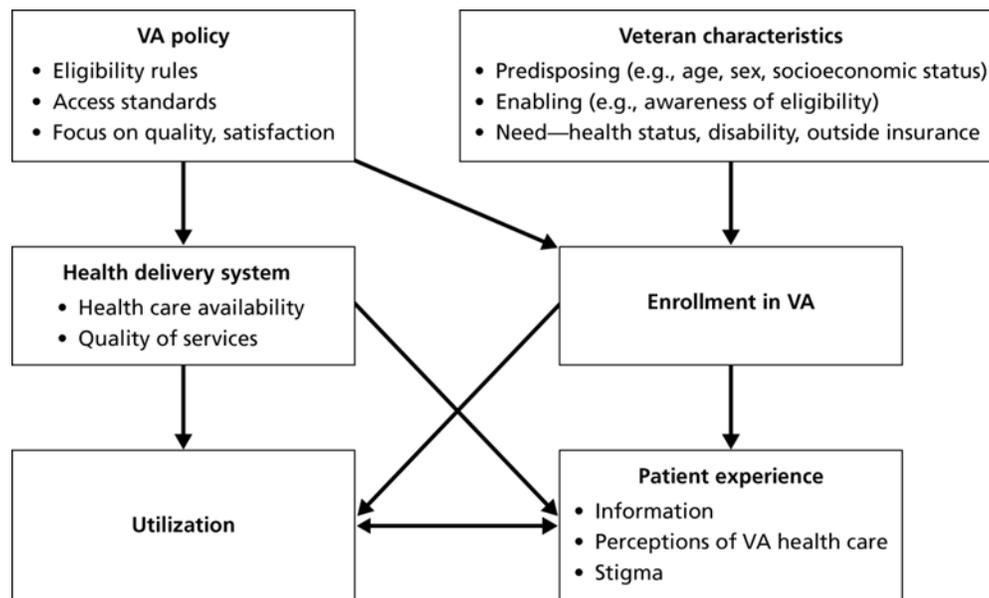
according to both our analysis and VA's (National Center for Veterans Analysis and Statistics, 2014b).

This increase in use of VA health care is likely due in part to the close to 300 percent increase in the number of pre-9/11, Gulf War-era Veterans receiving health care from FY 2000 to FY 2009 and extended enrollment for Afghanistan and Iraq Veterans (National Center for Veterans Analysis and Statistics, 2011b). The increases are also due in part to policy changes that have expanded VA's outreach to Veterans, eased the diagnostic criteria used to determine service-connected PTSD, and implemented the use of online application forms (Congressional Budget Office, 2014b). In addition, over time, VA has expanded the list of conditions that are considered to be presumptively related to service and therefore automatically render the Veteran eligible for benefits. For example, in 2001, VA granted presumptive eligibility status to Vietnam Veterans with type 2 diabetes, due to links to Agent Orange exposure (Congressional Budget Office, 2014b).

2.2 Factors Associated with Veterans' Health Care Utilization

A Veteran's decision to use VA health care depends on a number of factors, which are summarized in Figure 2-1, a conceptual model of health care utilization among Veterans, adapted from Aday and Andersen (1974). At a macro level, health care utilization is influenced by organizational policies and characteristics of the health care system. Health policy, especially in a large national health care system like VA's, is one of the primary drivers of health care utilization. As described in more detail below, VA has implemented numerous policies since the 1990s that have directly influenced Veterans' access to and use of VA health care. VA's health care delivery system also directly influences utilization. VA provides many services that are not available through non-VA sources, due in part to the needs of the unique patient population and to VA's social mission. Access, frequently measured in terms of wait times by VA, is also associated with use of health care services.

At the patient level, health care utilization is typically determined by three factors: predisposing factors (e.g., age), enabling factors (e.g., health insurance), and need for health care services, perceived or actual. Veterans, especially those using VA health care, have a different sociodemographic, health insurance, and health status than their peers who do not use VA health care. Finally, Veteran satisfaction with health care, including perceptions of quality, access, and stigma associated with certain treatments or care settings, also influence their health care utilization.

Figure 2-1. Conceptual Model of Factors Associated with Veterans' Use of VA Health Care


SOURCE: Based on Aday & Andersen, 1974.

2.2.1 Policies That Affect VA Use

Federal law authorizes VA to provide medically necessary health care services to eligible Veterans (U.S. Government Accountability Office, 2009). According to VA officials, federal laws and court decisions over the past decade have expanded Veterans' entitlement to a variety of VA benefits, not just health care (U.S. Government Accountability Office, 2013c). In the area of VA health benefits, legal and policy changes have attempted to expand and improve services provided to eligible Veterans. The foundation for this expansion began in the mid-1990s.

VA enrollment policies directly determine the number and composition of Veterans who are eligible to receive VA health care services. Veterans who have service-connected disabilities (including presumptive diseases) are given higher priority for VA health care, skewing the VA patient population toward Veterans with greater health care needs. VA-specific policies may also lead to a higher rate of diagnosis for some health conditions, such as mental health conditions.[8] Factors external to VA may also affect the number of Veterans who are eligible to receive VA health care and the choices of those eligible to use VA health services. Deployment and combat experiences are linked to higher rates of service-connected disability (Congressional Budget Office, 2014b), which translates into a larger number of Veterans eligible to enroll in VA and in part determines the prevalence of the health conditions among the newest Veterans.

---

[8] For example, in 2004, VA finalized a five-year Mental Health Strategic Plan, which emphasized mental health as an important part of Veterans' overall health, and its objectives included increasing early mental health screening and assessments.

In the 1990s, there was a "reengineering" of VA's health care system, with the purpose of improving performance, quality, and innovation (Congressional Budget Office, 2007). Prior to these changes, higher-income Veterans without service-connected disabilities were eligible for limited medical services, which did not include outpatient care (Congressional Budget Office, 2009). The Veterans' Health Care Eligibility Reform Act of 1996 revised VA eligibility rules, lifted the restriction on outpatient care, and expanded outpatient services in an effort to provide comprehensive health care to each enrolled Veteran (Veterans' Health Care Eligibility Reform Act of 1996, 1996). After the law, all enrolled Veterans were eligible for VA's full range of health care benefits, including outpatient services (Congressional Budget Office, 2009). Consequently, there was an increase in Veterans' use of VA outpatient care (Congressional Budget Office, 2009).

In 2000, the Veterans Claims Assistance Act (VCAA) clarified the duty of VA to assist benefits claimants, including actions to be taken for and information to be provided to Veterans (Veterans Claims Assistance Act of 2000, 2000). For example, VCAA required VA to assist a Veteran filing a claim in obtaining evidence to substantiate that claim before making a decision on benefits (Veterans Claims Assistance Act of 2000, 2000). VCAA also required VA to give the benefit of the doubt to Veterans in making benefits determinations. The "Combat Veteran" Authority of 2008 extended enhanced eligibility and expedited enrollment for VA health care for Veterans of Afghanistan and Iraq.

Recent years also have seen changes in VA policies related to women's health. These include the following requirements: each VAMC must have a Women Veterans program manager, who is responsible for assessing the needs of female Veterans (U.S. Government Accountability Office, 2009); all VAMCs and CBOCs must make comprehensive primary care available from one primary care provider at one site for all eligible female Veterans, including routine detection and management of acute and chronic illness, preventive care, basic gender-specific care,[9] and basic mental health care (U.S. Government Accountability Office, 2009); and all VAMCs and CBOCs must ensure the privacy[10] of female Veterans in all care settings. Federal law also now requires VA to provide mental health screening, counseling, and treatment for eligible Veterans who have experienced military sexual trauma (Counseling and Treatment for Sexual Trauma, 2011). Recent statistics show that 21 percent of female Veterans screened positive for military sexual trauma (U.S. Government Accountability Office, 2009). Even though the military sexual trauma law is particularly relevant to female Veterans, it applies to all Veterans.

---

[9] Gender-specific care is minimally defined as cervical cancer screening, breast examination, management of menopause, mammography, obstetric care, and infertility evaluation (U.S. Government Accountability Office, 2009).

[10] Privacy requirements include auditory and visual privacy at check-in and interview areas; the location of examination rooms, presence of privacy curtains, and orientation of examination tables; access to private restrooms in outpatient, inpatient, and residential care settings; and the availability of sanitary products in public restrooms at VA facilities (U.S. Government Accountability Office, 2009).

2.2.2 Characteristics of Veterans

2.2.2.1 Predisposing Factors

By *predisposing factors,* we mean demographic and socioeconomic characteristics that affect individuals' chances of using health care. Two demographic characteristics that set Veterans apart from the general population are age and sex, both of which are highly related to health care utilization. Veterans are significantly older and more likely to be male than non-Veterans (Goldberg, 2015; National Center for Veterans Analysis and Statistics, 2014d). Not only does an aging Veteran population face greater health care needs, but users of VA health care tend to be older than non-users (Congressional Budget Office, 2009; Elhai, Grubaugh, Richardson, Egede, & Creamer, 2008; Zeber, Copeland, & Grazier, 2006). Conditions such as hypertension and diabetes are more prevalent in older age. Large older cohorts of Veterans will continue to require additional services, including regular monitoring of health conditions, periodic diagnostic testing, and regular use of pharmaceuticals or other medical services, all of which will tax a burdened system.

In recent years, there has been a dramatic increase in the number of female Gulf War-era (pre-9/11 and post-9/11) Veterans seeking care (U.S. Government Accountability Office, 2009; Frayne et al., 2014). The number of female Veterans utilizing VA health care has doubled since 2003, and female Veterans accounted for 7 percent of patients seen in the VA health care system in FY 2013 (Frayne et al., 2014). Female Veterans face a burden of physical and mental illness similar to male Veterans (Frayne et al., 2006), are more likely than male Veterans to use VA health care exclusively (National Center for Veterans Analysis and Statistics, 2014d), and have higher health care expenditures than male Veterans (Bertakis & Azari, 2010; Bertakis, Azari, Helms, Callahan, & Robbins, 2000). The specific health care needs of female Veterans vary by service era (Washington, Bean-Mayberry, Hamilton, Cordasco, & Yano, 2013), with recent Veterans (of Afghanistan and Iraq) experiencing more health care encounters at VA than earlier eras.

Other demographic and socioeconomic characteristics, such as income, education, and employment, may also affect health care utilization decisions. In Section 3, we present results showing that Veterans and VA patients have higher average incomes than non-Veterans, that Veterans are more likely to be employed than non-Veterans, and that Veterans are more likely to have graduated from high school than non-Veterans. The relationship between socioeconomic status and health care use in the general population is complex; those with higher socioeconomic status are more likely to be insured and to have a usual source of care (Agency for Healthcare Research and Quality, 2014), but those with lower socioeconomic status tend to have poorer health outcomes and greater need for health services (Centers for Disease Control and Prevention, 2013).

2.2.2.2 Enabling Characteristics

In the context of this model, *enabling characteristics* are the means that individuals have available to them for use of services, which include individual-specific resources (such as income) and characteristics of the environment in which the Veteran lives (such as rurality).

Veterans may not fully understand their eligibility for VA health care benefits, services available at VA, how to apply for services, and the need for treatment for their condition (U.S. Government Accountability Office, 2011; Weeks et al., 2004; Wittrock, Ono, Stewart, Reisinger, & Charlton, 2015). One study found that the most common reason that potentially eligible rural Veterans did not use VA care was that they were unaware of their eligibility (Wittrock et al., 2015). Among rural non-enrolled Veterans, it was a common perception that VA enrollees were poor and were required to have experienced combat and a subsequent injury or disability (Wittrock et al., 2015). These findings are cause for concern because rural Veterans tend to have more physical health comorbidities and likely a greater need for VA health care services than other Veterans (Weeks et al., 2004). Some Veterans believe that VA services are focused on certain groups, such as older male Veterans, and are not available for women and younger Veterans (U.S. Government Accountability Office, 2011).

2.2.2.3 Need

Veterans with greater health care needs are both more likely to qualify for VA coverage and more likely to seek care at VA. Prior research has shown that Veterans with severe service-connected disabilities are particularly likely to seek health care from VA (Goldberg, 2015; McGeary, Ford, McCutchen, & Barnes, 2007). Similarly, mental health conditions and substance use disorders are associated with higher use of VA care (Virgo, Price, Spitznagel, & Ji, 1999). Afghanistan and Iraq Veterans with PTSD are using VA health care more frequently than Veterans of other eras (Elbogen et al., 2013; Shiner, Drake, Watts, Desai, & Schnurr, 2012). Data suggest that Afghanistan and Iraq Veterans with PTSD may also be at increased risk for poorer physical health in terms of medical disease burden (Possemato, Wade, Andersen, & Ouimette, 2010).

2.2.3 Health Delivery System

The availability of specific health care services through VA directly influences health care utilization. VA offers several services that are not readily available through other public or private insurance. For instance, VA offers extensive specialized mental health coverage and social worker services (Congressional Budget Office, 2009; Goldberg, 2015). Veterans are more likely to use VA for outpatient care and VA-emphasized services, including specialized mental health care for PTSD and outpatient psychiatric substance abuse counseling (Congressional Budget Office, 2009; Goldberg, 2015). These services may not be covered by private insurance, or the coverage may not be as extensive as VA coverage, which usually provides these services to Veterans with no or minimal cost-sharing (Congressional Budget Office, 2009; Goldberg, 2015).

At the same time, the lack of specific services at VA facilities may cause Veterans to seek care outside of the VA health care system or go without important treatment. For example, VA health care services for female Veterans are not widely available. Based on VA-provided workforce data, the Veterans Choice Act's Assessment B team estimates that only 81 out of 141 local VA health systems had an obstetrician or gynecologist on staff. Gynecologists were not available in one-third of VAMCs (Disabled American Veterans, 2015), and most CBOCs refer women Veterans to VAMCs, which may be up to 130 miles away, for gender-specific services

(U.S. Government Accountability Office, 2009). Several other gaps in VA health care services have been identified, including limited PTSD interventions in some VAMCs (Institute of Medicine of the National Academies, 2014b) and limited specialized PTSD programs for women Veterans (Disabled American Veterans, 2015; U.S. Government Accountability Office, 2009). Veterans tend to rely on non-VA providers for emergency services, inpatient care, and outpatient surgery (Congressional Budget Office, 2009).

2.2.3.1 Costs

Veterans enrolled in VA health care benefits do not pay enrollment fees, monthly premiums, or deductibles (Goldberg, 2015; U.S. Department of Veterans Affairs, 2015b). Some Veterans are required to submit co-payments for VA health care, which vary by priority group (U.S. Department of Veterans Affairs, 2015a). In general, Veterans in priority group 1 have no co-pays, Veterans in priority groups 2 through 6 face co-pays for some services, and Veterans in priority groups 7 and 8 face co-pays for most or all services.[11] Veterans who have co-pays are charged only one co-pay per day regardless of the number of appointments on that day. VA estimated that the annual out-of-pocket costs for VA health care among Veterans in priority groups with co-pays were $320 in 2014 (U.S. Department of Veterans Affairs, 2014b). This is likely an underestimate of the total costs to Veterans for their health care, given that enrolled Veterans receive most (70 percent) of their health care outside of VA (Goldberg, 2015).

Because many VA enrollees have access to other health insurance, costs associated with using VA services must be considered against the costs and convenience of external options. Growth in civilian health care costs, such as shifts toward high-deductible health plans in the employer health insurance market, may cause some Veterans to rely more heavily on VA. At the same time, some reforms implemented under the ACA, such as expanded Medicaid eligibility and access to premium and cost-sharing subsidies, may reduce Veterans' demand for VA care.

2.2.3.2 Quality

Studies have demonstrated that VA provides high-quality medical care overall (Congressional Budget Office, 2009) and for specific clinical populations (U.S. Department of Veterans Affairs, 2012). In fact, a 2004 article found that VA patients receive two-thirds of the care recommended by national standards, while patients in other health care systems receive about half of the recommended care (S. M. Asch et al., 2004). VA has certain initiatives in place, such as reviewing providers' actions following an adverse event, in an effort to improve the quality of care provided (U.S. Government Accountability Office, 2013b). Additionally, VA tracks the quality of its health care through numerous metrics, including patient satisfaction (Congressional Budget Office, 2007), adherence to clinical guidelines, patient use of VA Virtual Care Modality, geographic access, and wait times (Veterans Health Administration, 2015).

More-recent analysis conducted by RAND in Assessment B (part of this congressionally mandated study) concluded that VA health care quality was good overall; however, quality was uneven across the VA health care system, with marked differences between the highest- and

---

[11] For additional details, see U.S. Department of Veterans Affairs, 2015.

lowest-performing VA facilities. VA outpatient care outperformed non-VA outpatient care on most quality measures; however, inpatient quality measures varied. VA has served as a leader in the quality measurement arena and uses many systems for monitoring quality, but there are mixed opinions within VA on the impact of the quality measures.

Positive reports about quality may lead more Veterans to seek care through VA. However, it is unclear whether studies that have shown strong clinical quality outcomes in the VA health care system are widely known or understood among the Veteran population. Veterans may be influenced by findings that are reported in major newspapers, and could potentially be deterred from seeking care by recent reports of long wait times and other access problems. We discuss Veterans' perceptions about the VA health care system in Section 2.2.4.

2.2.3.3 Access

Under the Veterans Choice Act, *timely access* is defined as care provided within 30 days of the Veteran's desired date for an appointment. VA measures and routinely reports wait times for both primary and specialty care appointments for new and existing patients (Veterans Health Administration, 2015). However, wait time measures have been shown in recent years to be unreliable. Schedulers do not always record the desired appointment date in the scheduling system correctly, and scheduling policies are not always adhered to, resulting in the potential for inaccurate wait time calculations (U.S. Government Accountability Office, 2012). In other cases, wait times are not tracked, such as for VA-purchased care, which prevents VA from assessing whether non-VA care is meeting the wait time standards that apply to VA facility-based care (U.S. Government Accountability Office, 2014a).

Assessment B evaluated access to VA care and noted considerable variability across the dimensions of access. Geographic access varied by region and by access standard used (drive-time versus straight-line distance). Overall, most appointments met VA timeliness standards (30 days of preferred date); however, the average number of days that Veterans wait varies tremendously across the VA health care system. Veterans are less likely than patients in the private sector to report getting appointments as soon as needed.

In recent years, VA wait times have increased, resulting in a slight decrease in utilization, as well as adverse health outcomes among vulnerable Veterans (Pizer & Prentice, 2011). Delays in accessing care have occurred for patients seeking outpatient primary and specialty care within VA (U.S. Government Accountability Office, 2012, 2013a, 2014b). Veterans who received care at VA facilities with longer wait times were at increased risk of adverse long-term health outcomes (e.g., preventable hospitalizations) and intermediate outcomes (e.g., worse hemoglobin A1C levels) than Veterans receiving care at facilities with shorter wait times (Pizer & Prentice, 2011). The increase in wait times and associated adverse health outcomes were responsible, in part, for the greater use of technological methods to deliver care (e.g., messaging between patients and providers, telehealth) (U.S. Government Accountability Office, 2013a), and the development of legislation that expanded VA coverage to allow enrolled Veterans to seek VA-purchased care from community providers. In addition to the long wait times for VA patients, as recently as last year, nearly 1 million Veterans were stuck in a backlog waiting for their disability determinations to be evaluated (Hicks, 2014; Zoroya, 2014). Some of these individuals have an

initial disability determination, but are seeking re-evaluation to increase their disability ratings, which in turn could affect their co-payment requirements. Such backlogs may affect Veterans' ability to get timely access to care, because some will be unable to enroll, and others may face higher cost-sharing payments until their disability claims are adjudicated.

Long wait times and other access challenges likely deter Veterans from seeking care in two ways. First, long wait times and backlogs in processing disability claims pose barriers to accessing care among those who make an attempt to use VA services. Second, reports about long wait times, inconveniently located facilities, and other challenges may make some Veterans less likely to enroll or attempt to use VA services.

2.2.4 Patient Experience

The Aday-Andersen framework defines consumer satisfaction, or patient experience, as the "attitudes toward the medical care system of those who have experienced a contact with it." Veterans perceptions about the VA health system are also important predictors of health care use (Congressional Budget Office, 2009). One study found that media coverage of adverse events that occurred in VA facilities was associated with lower enrollment rates and subsequent Veteran disenrollment (Weeks & Mills, 2003). Facilities that had published reports of adverse events had lower enrollment rates after publication of the report (Weeks & Mills, 2003). Veterans' negative perceptions about VA health care influence Veterans' use of VA health care; these negative perceptions include both overall negative perceptions about VA and the treatment of Veterans by VA and more-specific perceptions that VA cannot meet their health care needs (U.S. Government Accountability Office, 2011). Veterans dissatisfied with their VA health care are more likely to seek care outside of VA (Stroupe et al., 2005).

Having considered the theoretical factors that influence a Veteran's decision to enroll in and use VA health care services, we now turn to our empirical approach, which makes use of a variety of DoD and VA data that capture experiences, characteristics, and environmental factors correlated with these decisions.

2.3 Analytic Approach

2.3.1 Overview

The goal of our assessment is to estimate the current and projected demographic characteristics and unique health care needs of the patient population served by VA. To accomplish this goal, we selected and synthesized data to estimate the size of the current Veteran population, their characteristics, the probability of using VA health care services, and trends over time in both the number of Veterans and their probability of health care use. Our baseline projections incorporated known trends and policy changes, such as DoD's ongoing "drawdown" aiming to reduce the size of the active duty force (Hagel, 2014; Parrish, 2011; Office of the Under Secretary of Defense (Comptroller), 2015). However, because many factors that could affect the size of the VA patient population are unknown and difficult to predict, we also considered uncertain future scenarios. These scenarios included both policies that are

within VA's control, such as a change in conditions that qualify for presumptive eligibility, and policies external to VA, such as the rollout of the ACA.

The number of Veterans who will ultimately seek care is determined by several factors, including the number of Veterans in the pipeline, Veterans' eligibility for enrollment, Veterans' decisions to enroll conditional on eligibility, and Veterans' decisions to use care when enrolled (Figure 2-2). These factors are influenced not only by VA policies but also DoD policies, trends in the generosity and availability of civilian health insurance coverage, geopolitical issues (such as the emergence of conflicts and the U.S. response), and Veterans' perceptions about the VA health system. Approaches to estimating future demand for VA health services must therefore consider previous utilization trends and current policies, as well as how these uncertain future scenarios could affect decisions. While our main analyses held policies and other factors that affect VA utilization constant (with an exception for the announced trends in the drawdown of the size of the military force), our scenario testing analyzed the impact of changes in Veterans' proclivity to use VA health services.

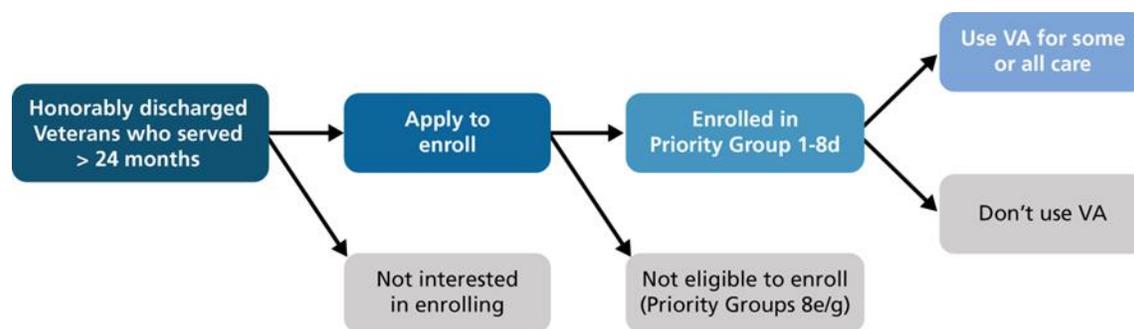
Figure 2-2. Pathway to Use of VA Health Care


Figure 2-3 describes the analytic approach that we undertook for this project. Briefly, the approach involved estimating the current number of Veterans and the share of Veterans who are currently VA patients, using data from sources such as the Census, ACS, and MEPS. We then projected both the size of the Veteran population and use of VA care over time, accounting for historical trends and known policy changes on the horizon. Finally, we considered how uncertain future scenarios may affect the size of the population and Veterans' proclivity to use VA services. The *use rate* refers to the probability of an individual becoming a VA patient given that he or she is a Veteran. A critical step to becoming a VA patient is the decision to enroll in VA health services. However, few available data sources combine information on Veterans, enrollment, and use of care. Because enrollment is an intermediate step that is not critical to answering all of the questions posed by Congress, we did not necessarily consider enrollment in all of our analyses. In analyses that required estimating enrollment, we predicted the enrollment rate and the *conditional use rate*, which is the use rate among enrollees (as opposed to the overall use rate among all Veterans). The overall use rate is illustrated by the curved arrows in Figure 2-3, and the enrollment and conditional use rates are illustrated with straight,

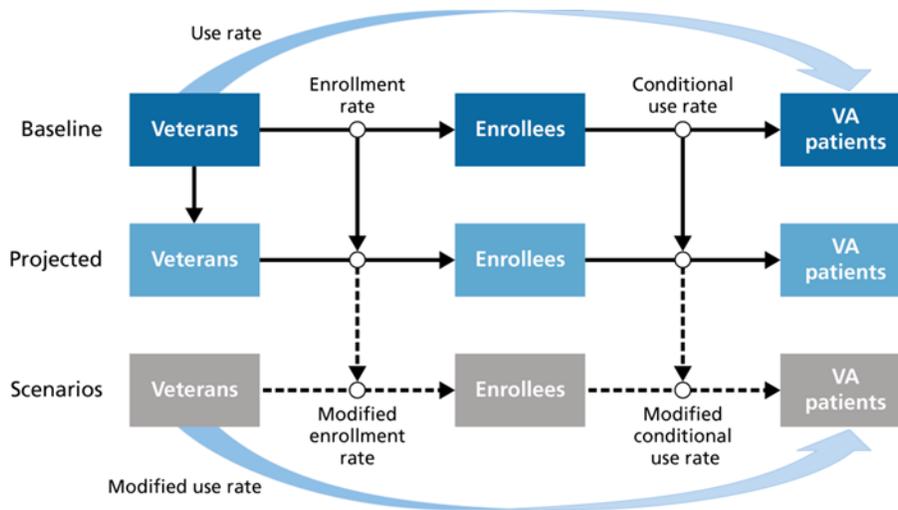
horizontal arrows. Mathematically, the overall use rate represents the product of the enrollment rate and the conditional use rate.

When considering uncertain future scenarios, we modified the enrollment and the use rates among those enrolled to account for potential changes that may occur due to future events. For example, a policy that would loosen restrictions on enrollment among Veterans in priority groups 8e and 8g would affect both the probability of enrollment and the probability of using care conditional on enrollment.

Figure 2-3. Analytic Framework


2.3.2 Baseline 2014 Population Estimates

To develop our baseline estimates, we started with data from the 2000 Census (the most recent national accounting of Veterans; the 2010 Census did not assess whether respondents were Veterans), and appended that data with more-recent information on Veterans from ACS, an annual survey conducted by the U.S. Census Bureau that collects information on Veteran status, demographic characteristics, and insurance coverage. To account for newly discharged Veterans and reservists since the 2000 Census, we incorporated data from DoD, including the Defense Manpower Data Center (DMDC) Active Duty Loss files, the Work Experience (WEX) files, and the Contingency Tracking System files. These data sources are described in more detail later in this section and in Appendix A. With this information, we were able to develop a comprehensive picture of the current Veteran population, including demographic characteristics such as age, sex, geographic location, race/ethnicity, and service era.

Because the demographic files described above do not contain information on Veterans' health status or use of health care, we turned to other data to assess this information. One important source of information was MEPS, which collects information on health care conditions and use of services for the U.S. noninstitutionalized population, including Veterans. With these data, we could identify whether an individual is a Veteran, whether the individual reports VA as a source of health coverage, whether the individual received any health care paid for by VA, what types

---

of conditions and illnesses the individual experienced in the past year, and treatments received in the past year. Because MEPS collects comprehensive information on both VA and non-VA care, we could use the data to understand Veterans' health care needs regardless of whether they sought treatment from VA sources. In addition, because MEPS collects information on both Veterans and non-Veterans, we could use the data to compare Veterans' health conditions and comorbidities with non-Veterans' health conditions and comorbidities. A drawback of MEPS, however, is that its relatively small sample size precluded us from using these data to investigate extremely rare conditions, such as amputations, that are of high interest to VA. In addition, because diagnoses are based on self-reports, MEPS could miss key conditions, especially those associated with stigma (e.g., mental health conditions) (Agency for Healthcare Research and Quality, 2004).

As an additional source of data on the health status of the VA patient population, we turned to encounter data from the VA health system. The encounter data record every patient interaction that a Veteran has with the VA health system, enabling us to get a comprehensive picture of care and diagnoses delivered by VA. With these data, we could count the total number of VA patients and analyze treated Veterans' recorded diagnoses, including diagnoses for rare conditions such as amputations, burns, blindness, TBI, and spinal cord injury. Further, because the encounter data record all patient interactions, it is not subject to recall bias or other reporting biases. However, the encounter data do not contain information on care or diagnoses received outside of VA, and the administrative nature of the data can make it difficult to separate true diagnoses from diagnosis associated with encounters to "rule out" disease (e.g., if an individual receives a test for diabetes but the results are negative, this visit may nevertheless have an associated diabetes diagnosis code in the encounter data).[12] Further, the data contain no information on non-Veterans (other than a small number of Veterans' family members who are eligible for care), making it impossible to use VA encounter data to compare Veterans' diagnoses with non-Veterans' diagnoses.

Despite these limitations, the combination of the MEPS data and the VA data allowed us to develop a nuanced understanding of Veterans' health care needs. With MEPS, we could assess needs of all Veterans whether or not they use the VA health system, and we could compare these needs with the needs of non-Veterans. With the VA encounter data, we could access more-detailed information on the unique health care needs of the current VA patient population.

---

[12] In our analysis with the VA encounter data, we attempted to identify conditions with greater accuracy by requiring that one inpatient encounter be labeled with the associated conditions or that two outpatient encounters were labeled with the associated conditions; this is a common approach for identifying conditions within VA encounter data (Park et al., 2014). We made exceptions for TBI, acute coronary syndrome, and acute myocardial infarction (AMI). We identified TBI cases even if there was only a single outpatient or inpatient diagnosis flagged because acute causes of TBI (concussion, skull fracture, etc.) may be described only at the initial visit, per guidance from DoD (U.S. Department of Defense, 2010). In contrast, we identified acute coronary syndrome and AMI if one or more inpatient stays had a principal diagnosis code associated with those conditions (Petersen, Wright, Normand, & Daley, 1999).

To understand transitions between becoming an enrollee and becoming a VA patient at baseline, we relied on administrative data from VA that record the total number of enrollees overall and by subgroup (e.g., based on priority status). We also used the encounter data to determine the number of unique VA patients in a given year. However, there was no definitive source of information on the total Veteran population living in the United States. Like the VA OACT, we therefore had to rely on Census and survey data to estimate the size of the total population.

2.3.3 Population Projections

We projected the future size and demographic characteristics of the Veteran population by combining several sources of information, including:

- Past trends in the size and characteristics of the Veteran population observed in historical data
- Statistical models of migration patterns used by demographers, known as "gravity models" (defined in Section 3)
- Information on the characteristics and size of incoming Veteran cohorts, based on DoD data on the current active duty population, annual discharge patterns, and projected plans to reduce the size of the force
- Projected mortality rates among Veterans derived from the Centers for Disease Control and Prevention (CDC) and the VA OACT.

We combined this information to develop detailed annual estimates of how the Veteran population will change between 2015 and 2024, accounting for trends in demographics, migration patterns, and projected mortality rates. For example, our approach accounted for the fact that newly discharged Veterans are more likely to be female and more likely to be Hispanic than the existing population of Veterans (although, despite these trends, Veterans are still disproportionately male and primarily non-Hispanic).

To project VA patient status over time, we estimated the use rate, or the probability that a future Veteran will use VA for health services. We used administrative data from VA to model the probability that a Veteran will use VA health services, accounting for demographic characteristics and historical time trends in the proclivity to access care at VA. The projected use rate was combined with the Veteran population projections to estimate the number of VA patients in each year from 2015 to 2024.

We used statistical models to estimate the health conditions of the total Veteran population and the VA patient population, taking into account such factors as age, sex, race/ethnicity, Census region, and historical time trends. This information was appended to our projections of the size and demographic composition of the Veteran and VA patient populations, and allowed us to project the health conditions of Veterans and VA patients in each year between 2015 and 2024. In projecting the future health conditions of Veterans and VA patients, we also considered the health conditions of the current active duty force, using encounter data from MHS.

2.3.4 Scenarios

The projected trends in the Veteran population and VA patient population described above are based on a "steady state" and are driven by predicted changes in Veteran population demographics and observed trends in health care needs; they do not account for uncertain future scenarios that might affect the composition of the Veteran population and Veterans' health care use. In Section 6, we consider the impact of uncertain policy changes and external trends that could affect demand for VA services. The scenarios we consider focus on factors that could affect the number of Veterans in the pipeline (e.g., possible future conflicts), factors that could affect Veterans' eligibility to receive care (e.g., changes in enrollment prioritization, changes in conditions that grant presumptive eligibility status), and factors that could affect Veterans' use of care when eligible (e.g., expansions to the Veterans Choice Act; eligibility for new, non-Veteran programs due to the ACA).

The scenario tests build from our baseline projections, incorporating possible changes in the size of the population and Veterans' propensity to use VA services. An inherent limitation of the scenario testing section is that, because we were modeling uncertain future events, we did not always have access to reliable historical information that we could use to estimate effect sizes, and instead needed to rely on relatively strong assumptions. For example, in estimating the effects of a potential future conflict on the size of the VA population, it is unclear that we could draw meaningful insight from experiences of prior conflicts (e.g., Vietnam, World War II) because technologies, methods of fighting, and military strategic approaches have changed dramatically over time. For the future conflict scenario, we relied on military staffing patterns observed during the most-recent conflicts (Afghanistan and Iraq), but we recognize that even these recent conflicts could be quite different from what might occur in a hypothetical future conflict. As a result, the output of our scenario testing is by definition highly uncertain. Nevertheless, this type of evaluation is important for contingency planning and understanding the possible magnitudes of demand shifts that VA could face if large-scale changes should occur. While any given scenario is unlikely to come to fruition in exactly the manner we have posited, analyzing possible changes in demand may help VA to respond quickly when unforeseen circumstances arrive. For example, a modeling strategy could be altered or updated as better data or more-specific policy details emerge.

2.4 Existing VA Forecasting Models

For the purposes of this independent assessment, we implemented our own modeling approaches to estimate the current and future demographics of the Veteran population and their health care needs. However, VA has three existing modeling tools that it uses to estimate future demand, including VetPop (a model of the Veteran population), EHCPM, and the VA OACT's Veteran Healthcare Scenario Model (VHSM). In this section, we briefly describe each of these models. However, the amount of available documentation for the models varies. We had access to detailed documentation for the EHCPM but not the other two models. As a result, we are able to offer a more thorough description of the EHCPM model.

2.4.1 VetPop

The VetPop2014 model was developed by OACT for Veteran population projections from 2014 to 2043. The model provides Veteran counts by age, sex, service era, and race/ethnicity at the county level. VetPop2014 is the culmination of years of work and refinement by OACT, representing the seventh iteration of the projection model (the previous iteration was developed in 2011). Documentation for the VetPop2014 model is scarce, and we rely on information contained in an online two-page abstract and discussions with the VetPop2014 team at OACT (Office of the Actuary, 2014).

Vetpop2014 starts with a baseline population, then applies mortality rates and adds new Veterans over time. The model also accounts for Veterans' migration patterns throughout the forecasting period. The baseline population for the VetPop2014 model comes from the 2000 U.S. Census. VetPop2014 then applies age- and sex-specific mortality rates derived from mortality data that include Veteran-specific information from VA administrative data and U.S. population data from the Social Security Administration and the Internal Revenue Service (IRS). Mortality rates in VetPop2014 vary by age and sex. VetPop2014 assumes a slight mortality improvement for older Veterans due to expected increases in life expectancy.

VetPop2014 projects annual separations from the military (i.e., new Veterans) by age and sex, and by active and reserve component, using DoD data. The abstract states that "[b]ased on DoD's annual military separation data from FY1980 to FY2013…VetPop2014…developed a set of Time Series Models to project annual separations for various age and gender groups. . . . VetPop2014 Model then used historical county separation data based on VA administrative records along with migration information from the IRS to project the county level separation from FY2014 to FY2043 using predictive modeling techniques." VetPop2014 assumes that conflicts in the Gulf end by 2018, and that there are no other major conflicts in the next 30 years. Finally, VetPop2014 models migration at the county level using historical data from VA, IRS, and ACS. Predictive migration models are developed for various age (five groups) and sex cohorts.

2.4.2 Enrollee Health Care Projection Model

EHCPM is a model for projecting how Veterans will interact with the VA health care system, and what consequences VA will experience as a result. The model is organized into three stages, which predict (1) eligibility and enrollment of Veterans in VA health care, (2) Veteran demand for health care services and reliance on VA health care for those services, and (3) total cost to VA of providing services. Each stage is contingent on projections from the previous stages, as well as external data and models.

At the highest level, EHCPM calculates costs as the product of Veterans, demand per patient, a reliance factor representing the proportion of care that Veterans receive from VA, and a unit cost:

$$Veterans * \frac{Demand_{Total}}{Veterans} * \frac{Demand_{VA}}{Demand_{Total}} * \frac{Unit\ Cost_{VA}}{Unit\ Demand_{VA}} = Costs_{VA}$$

This process is repeated for many Veteran subpopulations (defined by geography, demographics, priority group, and other characteristics) and for many categories of health care services.

EHCPM is a policy and planning model. It serves three functions for VA. First, the model provides a principled way to anticipate future demand for VA services, so that administrators can plan accordingly. Second, the model enables VA to provide Congress with an estimate of future costs, which, in turn, helps to ensure that its congressionally apportioned budget is sufficient to meet service demand. Third, because political, cultural, and demographic factors strongly shape the VA operating environment, EHCPM enables administrators to understand the operational consequences of factors both within and beyond VA's control.

In this regard, a key feature of the model is its ability to produce estimates for hypothetical scenarios, such as new legislation. EHCPM decomposes model outcomes into a series of joint probabilities, each of which can be altered to simulate the impact of scenarios and project the consequences for VA health care. For example, the probability that a Veteran uses services can be decomposed as the probabilities of: enrollment in VA care × reliance on VA over alternative sources of insurance × patient demand for health care services. If a new piece of legislation had the potential to raise Veteran co-pays, that might lower the probability that Veterans rely on VA care instead of alternative insurance options. The model could be recalculated with an artificially lowered reliance rate, enabling planners to understand how the proposed legislation would affect patient demand for VA services.

The joint probability strategy greatly increases the volume, variety, and specificity of the data required. To project enrollment of Veterans in VA health care, EHCPM relies on (1) actual enrollee and user data from internal records; (2) estimates of the characteristics of the total Veteran population, which is itself a multidata-source model projection from the VA OACT; (3) DoD data on deployment and separation of military personnel; and (4) actuarial mortality tables. To project health care demand and Veteran reliance on VA for it, EHCPM relies on (1) user data from internal records on Veteran characteristics and diagnoses; (2) the VA Survey of Veteran Enrollees' Health and Reliance Upon VA (SoE); (3) Medicare data for Veterans age 65 or older; (4) Chronic Illness & Disability Payment System data from the University of California, San Diego on the relationship between diagnoses and usage patterns for chronic illness/disability; (5) data from the actuarial firm Milliman's *Health Cost Guidelines* on health care utilization and cost averages by geographic area; and (6) various proprietary scores developed by Milliman. To project health care costs, EHCPM relies on (1) VA unit cost, workload, and budget obligations data; (2) CMS data on the work required to provide various physician services; and (3) Milliman data on the workload burden of providing various outpatient hospital services. Each stage of the model relies on outputs from the previous stage. In many instances, EHCPM uses linear modeling, with some analyst discretion in model specifications,[13] to extrapolate needed figures with no suitable data source. Finally, many model inputs are smoothed to account for temporal or categorical progression and trends.

---

[13] These adjustments are reviewed by another actuary at Milliman who is not directly involved with the EHCPM work.

At each step, model projections are calibrated against the previous year's actual statistics. This involves running the model for the previous year, and then calculating an adjustment statistic for each model output to make model outputs identical to the previous year's actual figures. These adjustment statistics are then applied to the future projections, which predict various aspects of VA health care over the next 20 years. Analysts also examine these adjustment figures for trends, as trending adjustments may be the first sign of an underlying change in the health care system.

2.4.3 Office of the Actuary Veterans Health Care Scenario Model

Based on conversations with the VA OACT, VA uses VHSM for strategic planning and specifically to evaluate the budget impact of various business scenarios. By applying multiple analytic methods, VHSM produces analysis of key drivers and three types of model outputs: (1) baseline models, (2) scenario models, and (3) stochastic models. The key-drivers analysis is used to evaluate the trends and important factors influencing eligibility and demand for VA services, utilization of these services, and corresponding costs. The baseline model can then identify gaps in VA services in terms of demand and associated costs, while the scenario model can be used, for example, to understand how the changes in Veteran population demographic characteristics or economic conditions (such as income or employment) can influence the demand for VA services and related costs. The stochastic models are the Monte Carlo Simulations of the likelihood that VA will actually meet the demand for its services, given its budget limits, if the scenario under consideration is realized.

OACT relies on many data sources in its analysis: (1) VA administrative data (enrollment files, patient utilization files, benefits data), (2) public data (MEPS for medical expenditures, CMS data on Medicare and Medicaid, U.S. Census for socioeconomic demographic data, DoD data for new Veterans, and the Social Security Administration for mortality and disability data), and (3) industry and commercial data (Society of Actuaries health care trend analysis, United Health Group claim data for utilization and cost benchmarks, and Acxiom data for socioeconomic analysis).

2.5 Strengths of Our Approach

VA has made substantial investments in the models described above and refined them over the years. Our analysis, which was done on an eight-month time frame with limited access to data, was not meant to replace current VA models. Rather, we aimed to provide an independent assessment of the current and future Veteran population and patients' need for health services. In addition, while our models are prototypes and have not been refined to the same extent as VetPop and EHCPM, we incorporated several features into these model that could be useful for future VA planning. Strengths of our approach include the following.

Use of DoD data: We incorporated several sources of data from DoD into our models, to enable us to refine our estimates of the pipeline of future Veterans and their health care needs. By using the combination of the DMDC loss files, WEX files, and Contingency Tracking System files, we were able to account for age, sex, race, branch, active duty status, and activated reserve status in our demographic projections. To the best of our understanding, the VetPop model

relies on aggregate rather than micro-level DoD data, and accounts for only age, sex, and service era in projection models, although race/ethnicity estimates are ultimately presented among the characteristics of future Veterans.

In addition, we incorporated health status information from MHS into our estimates of Veterans' future health care needs. We do not believe that MHS data or other data on current military populations is incorporated into EHCPM. Better anticipating the needs of incoming Veterans could improve model accuracy.

Effort to incorporate race/ethnicity: The DoD data we used to enhance our projections include information on race and ethnicity, enabling us to estimate how changes in the racial and ethnic composition of the current military force may affect the demographics and health care needs of future Veterans. In addition, we incorporated race/ethnic-specific mortality rates from CDC into our model, adjusted to account for overall differences between Veteran and non-Veteran mortality. In contrast, mortality rates in VetPop account only for sex. A more nuanced focus on race and ethnicity may help VA to better understand the evolving needs of the VA population, especially because the number of Hispanic Veterans is increasing.

Use of MEPS to estimate reliance: VA faces a significant challenge in estimating future demand for health services due to the issue of reliance, or the fact that many Veterans receive only a portion of their total health care from VA. Reliance raises two important sources of uncertainty in estimating future demand: Reliance patterns may shift over time, and existing VA administrative data do not provide visibility into the total health care utilization and needs of the patient population. EHCPM appends VA data with Medicare claims data to estimate reliance for patients age 65 and older, and use a combination of VA survey data and proprietary commercial utilization benchmarks to estimate reliance among Veterans under age 65.

We took a different approach, using MEPS to estimate Veterans' reliance and propensity to use VA health care. MEPS is a survey of the noninstitutionalized civilian population (including Veterans) that aims to understand the U.S. population's total demand for health services and use of care across all possible settings. Because the survey identifies Veterans and assesses how they pay for health care, we were able to use this data to infer total utilization, whether or not care was provided by VA, as discussed in Section 5. Relative to current surveys conducted by VA, MEPS provides greater detail on the use of health services and specific diagnoses. Further, MEPS data suggest that Veterans over age 65 use other sources of care besides VA and Medicare (e.g., private insurance, self-pay), raising questions about VA's current approach to estimating reliance among this population.

MEPS has some significant drawbacks in terms of its utility for VA planning. Most importantly, the sample size of Veterans in MEPS is small, and the survey is not currently designed to ensure that the demographic distribution of Veterans is accurately preserved. For these reasons, it is unclear whether relying on MEPS in its current form would significantly enhance VA's forecasting capability. However, it is possible that the methods employed by MEPS to estimate health care use for the general population could be tailored to support a similar survey of Veterans.

***Scenario testing*:** We tested the sensitivity of our estimates to alternative (but plausible) scenarios in which the number of eligible Veterans and Veterans' proclivity to use health care were altered relative to our initial projections. Our analysis considered both the impact of policy changes that VA could enact on its own, as well as the impact of policy changes and external trends that are beyond VA's control. The scenarios helped us to understand what types of policy change and events might significantly change the demand for VA services, and hence require changes to planning approaches. While it is unlikely that any of the specific policy scenarios will unfold in exactly the manner we have modeled, the approach is useful to understand the potential impacts of uncertain future events. Conducting regular sensitivity analyses related to potential changes in Veterans' eligibility and utilization patterns could help VA to be better prepared when unforeseen circumstances arise.

We reiterate that our analysis was not meant to replace ongoing VA modeling efforts. Rather, we aimed to provide a fresh perspective on potential modeling approaches, and to provide insight into how different methodologies might affect results.

2.6 Overview of Data Sources

Throughout this report, we use a variety of data sources that provide information on populations (civilians, service members, Veterans, VA enrollees, VA patients) and their characteristics. Table 2-3 summarizes the populations in each data set, including the National Health Interview Survey (NHIS), the Behavioral Risk Factor Surveillance System (BRFSS), and the National Survey of Veterans (NSV), among others; indicates whether health and geographic information is included; and denotes specifically whether we could determine if an individual was eligible for VA services, was enrolled in VA, and was a VA patient. The passages following Table 2-3 briefly discuss the main advantages and limitations of each available data source.

Table 2-3. Summary of Data Sources

Data File	Population	Health	Geographic Location	Veteran Status	VA Enrolled	VA Patient
Nationally Representative Surveys						
MEPS[a]	Civilians, Veterans, VA patients	Yes	Census region	Yes	Yes	Yes
NHIS[b]	Civilians, Veterans, VA enrollees	Yes	Census region	Yes	Yes	Yes
BRFSS[c]	National Veterans, civilians	Yes	State	Yes	Yes	Yes
U.S. Census	Civilians, Veterans	No	Yes	No	No	No
ACS[d]	Civilians, Veterans, eligible Veterans, enrollees	Limited	Yes	Yes	Yes	No
Veteran/VA Surveys						
NSV	Veterans	Limited	No	Yes	Yes	Yes
SoE	VA enrollees	Limited	Yes	Yes	Yes	Yes
Administrative Data						
VA Encounter	VA patients	Yes	Yes	Yes	Yes	Yes
VA Enrollment	VA patients, VA enrollees	No	Yes	Yes	Yes	Yes
TRICARE/MHS	Active duty military	Yes	Yes	N/A	N/A	N/A
Active Duty Master and Loss	Active duty military	No	No	N/A	N/A	N/A
Work Experience	Service members	No	No	N/A	N/A	N/A
Contingency Tracking System	Service members	No	Yes	N/A	N/A	N/A

Note: For the survey data sources, details vary regarding how Veteran status, enrollee states, and patient status is assessed. Table 2-4, below, reports details on Veteran status is determined. Enrollee status is typically based on a self-report of enrollment or use of VA insurance. Patient status may be inferred in some cases based on utilization of VA services and/or payment for services by the VA.

[a] See Medical Expenditure Panel Survey, undated.
[b] See Centers for Disease Control and Prevention, 2012.
[c] See Centers for Disease Control and Prevention, 2014a.
[d] See U.S. Census Bureau, 2015.

The **Medical Expenditure Panel Survey (MEPS)**, sponsored by AHRQ, is a recurring nationally representative longitudinal survey of the U.S. civilian noninstitutionalized population drawn from the NHIS sampling frame. The Household Component of MEPS collects information on medical utilization, expenditures, and sources of payment for care obtained by households in all care settings outside of nursing homes. It also includes detailed information obtained via

questionnaires provided to households and separately to their medical providers. Demographic information includes age, sex, race/ethnicity, marital status, education, and income, but does not include information on service era. Health information is derived from responses to survey questions about several common medical conditions and responses to open-ended questions about medical conditions or procedures. These open-ended questions are translated into International Classification of Diseases, 9th revision (ICD-9) codes that are used for analysis. MEPS does not contain sufficient information to precisely determine eligibility or enrollment in VA services. Given these limitations, we define Veterans as those respondents who report being honorably discharged from the military,[14] and we define active VA patients to be those respondents who had any payment by VA for services used.[15] The period of analysis covered data from 2006 to 2012.

MEPS has several strengths relative to other possible data sources that we could have used for this analysis. First, the goal of the assessment was to analyze the health care needs of the patient population served by VA. We interpreted this to include all health care needs, not just health care needs addressed by VA providers or paid for by VA. Because many VA patients receive a large portion of their health care needs from non-VA sources, we felt it was important to use a data source that captured non-VA care. MEPS allows us to identify all care consumed by a VA patient, not just care provided by VA. The fact that use of VA care is influenced by access barriers makes it even more critical to consider episodes of care provided outside of VA. Focusing only on care provided by VA would understate both the total needs of the VA population and the underlying need for VA services.

Second, MEPS allows us to identify the health care needs of Veterans who do not currently use VA for any care. This population is important because many of these Veterans are potential VA patients, and could opt to use VA care in the future. We recognize that some of these Veterans are not currently eligible to enroll in the VA system. However, VA enrollment policy is fluid and changes over time, and VA has discretionary authority to provide care for all Veterans. For example, VA suspended enrollment for Veterans in priority group 8 in 2003, and then relaxed some of these restrictions in 2009. Thus, fully understanding the needs of the future patient population requires considering the needs of Veterans who are not currently eligible to enroll.

Third, MEPS allows us to compare the health care needs of Veterans with the health care needs of non-Veterans using a single data source that collects information using the same methods for both groups. This comparison is important to understand the unique health care needs of the VA population, a requirement identified by Congress.

The **National Health Interview Survey (NHIS)**, sponsored by CDC, is an individual-level annual survey that includes information on demographics, Census region, general health, cancer screening, self-reported medical conditions (including asthma, arthritis, cancer, diabetes), health behaviors (including alcohol use, smoking, exercise), physical or functional limitations, and mental health (adult mental health, stress). We defined eligible Veterans to be those who

---

[14] Prior to 2006, the survey instrument asked whether anyone in the household had *ever served on active duty in the Armed Forces of the United States* [emphasis added]*.*

[15] Methodology for identifying Veterans is discussed in Roemer, 2012.

self-reported having served in active military duty. It is not possible to identify VA patients in these data. We analyzed data from 2011 to 2013, which covers the period when military service information is available. We used NHIS to estimate the prevalence of the selected health conditions among Veterans and non-Veterans. Where possible, we compared these estimates with those derived using MEPS, which were based on ICD-9-coded health conditions.

The **Behavioral Risk Factor Surveillance System (BRFSS)**, sponsored by CDC, is a nationally representative survey fielded monthly by state health departments that collects individual-level information on health behaviors and risk factors associated with the leading causes of premature mortality and morbidity among adults in the United States. We used data covering 2013. The survey allows for periodic experimental modules and for states to ask additional questions beyond the core instrument. The survey asks whether respondents have ever served in active military duty in the core instruments, and we used this response to identify Veterans. There are also several experimental modules (for certain states) that have asked more-detailed questions about deployment, service, and a few specific Veterans' health issues (e.g., PTSD, TBI), but we did not use this information because the sample sizes were small and the populations were not nationally representative. We used BRFSS to estimate the prevalence of the self-reported health conditions among Veterans and non-Veterans. BRFSS was also used to examine differences in health behaviors (e.g., smoking) and other health indicators (e.g., obesity) between Veterans and non-Veterans.

The **U.S. Census** collected information about the 115.9 million housing units and 281.4 million people in the United States on April 1, 2000. A 5-percent sample of people and housing units received a more detailed long-form survey that contained questions about Veteran status and periods of service. As a starting point, the team used the 5-percent sample 2000 Census data to assess the baseline Veteran population in 2000. The 2010 Census did not include a long form and did not collect information on Veteran status. The 2010 Census short form included only basic demographic questions (e.g., name, relationship with head of household, age, sex, Hispanic origin, race) and household information (e.g., number of people in the household, whether the home is owned or rented). The 2000 Census long form asked detailed demographic and household questions, including Veteran status and time that the person served on active duty in the U.S. armed forces. As of the 2010 Census, detailed sociodemographic and other information is collected in ACS, rather than the Census.

The **American Community Survey (ACS)** is an ongoing mandatory survey conducted by the U.S. Census Bureau that collects data each year to bridge intercensal periods and provide detailed information about the population, including Veteran status. ACS also includes information on current location and location in the previous year. Our analysis uses ACS to determine Veteran geographic distribution and migration patterns. It was not possible to use ACS to accurately measure the number of Veterans in the population; ACS is generally acknowledged to undercount Veterans, though it is assumed to accurately capture the distribution of Veteran characteristics (age, sex, race/ethnicity, service cohort, location). For example, the 2013 ACS estimates of total Veteran population are roughly equivalent to our own estimates of the number of Veterans observed in the 2000 Census who are estimated to still be living in 2013—that is, ACS estimates effectively undercount by the number of new Veterans who entered the population from 2000–2013. For this reason, the team produced a set of population projections

using a combination of Census 2000 data, DoD data, and ACS data. More specifically, the team used the 2005–2009 and 2009–2013 ACS 5-year estimates available through the American FactFinder website (U.S. Census Bureau, undated). ACS data prior to 2005 do not have information about residence in previous year, which is necessary for migration estimates.

The **National Survey of Veterans (NSV)**, sponsored by VA, is a recurring nationwide survey of Veterans, military service members, and their families. Our analysis used the 2010 NSV survey. NSV data include individual-level demographic and socioeconomic characteristics, general health status, branch of service and period of active duty, and self-reported enrollment in VA and use of VA benefits and services. NSV data were used to estimate characteristics of current Veterans who use VA medical services and how these differ from Veterans who are not VA patients.

The **VA Survey of Veteran Enrollees' Health and Reliance Upon VA (SoE)** is a recurring nationwide survey of more than 40,000 Veterans enrolled in the VA system. The survey includes each enrollee's demographic and socioeconomic characteristics, general health status, period of military service, and priority group (from administrative record). It also includes information relevant to enrollees' relationships with the VA system, including when and why individuals enrolled in VA, health insurance coverage, long-term care insurance, use of VA and non-VA services, and payer information. We used this survey to determine the characteristics of Veteran VA enrollees predicting use (or non-use) of VA services and, in combination with demographic projections, future rates of VA use.

VA encounter data include individual-level information on diagnoses, demographic characteristics, and geographic location (state). VA encounter data were used to estimate current and prior condition prevalence patterns among active VA patients. These data include all health care encounters provided or paid for by VA, which allowed us to estimate the prevalence of service-connected health conditions that exhibit very low prevalence in the national population. A limitation of these data is that they do not capture Veterans who did not use VA care. Moreover, the database includes only health conditions of VA patients that were treated at VA. This may represent only a subset of total health conditions if VA patients also seek care from non-VA providers. Most Veterans with service-connected disabilities use VA (RAND analysis of FY 2014 VHA Support Service Center Current Enrollment Cube data), so the prevalence estimates for these conditions are expected to be more representative of the overall prevalence in the Veteran population.

VA enrollment data are derived from the Health Eligibility Center enrollment files via the VA Business Intelligence System Current Enrollment Cube and the Assistant Deputy Under Secretary for Health (ADUSH) enrollment file. These sources include the counts of VA patients and VA enrollees by state of residence, sex, age group, and Iraq-Afghanistan deployment status. We used data covering 2005 to 2014.

Military Health System (TRICARE) encounter data include information on diagnoses and demographic characteristics of active military personnel. We used TRICARE data to estimate the prevalence of health conditions among separating personnel, which may be useful in predicting health conditions among future VA service users and in determining variation in demand for VA services by health condition.

The **Active Duty Master and Loss files** provide an inventory of all individuals on active duty (excluding reservists on active duty for training) for the Army, Navy, Marine Corps, Air Force, Coast Guard, Public Health Service, and National Oceanic and Atmospheric Administration Commissioned Corps at a point in time. Relevant personal data elements include date of birth, sex, race, and ethnic group. Relevant military data elements include months of service and basic active service date, as well as anticipated service contract end date. The Active Duty Military Personnel Transaction file contains a transaction record for every individual entrance, separation, or reenlistment in the Army, Navy, Air Force, Marine Corps, and Coast Guard within a specific time frame. The Active Duty Loss files are subsets of the Master/Transaction file. The team used these data to supplement the 2000 Census counts for April 2000 to December 2014. Each separation, or "loss," indicates an incoming Veteran to the civilian population.

The **Work Experience (WEX) file** contains a longitudinal record for each individual who has served in the active or reserve forces since September 1990. For those individuals, the WEX includes information on service back to 1975. The file is organized by "transactions"; in other words, a new record is generated whenever there is a change in the key variables—service/component/reserve category, pay grade, occupation (primary, secondary, or duty), and unit identification code. The WEX is built from information in DMDC's Active Duty Master Personnel Edit file, equivalent reserve files, and the underlying service files.

The **Contingency Tracking System** is an administrative data set that contains one record for every activation or deployment in support of the conflicts in Afghanistan and Iraq. These deployment data were linked to the DMDC Loss files in many analyses throughout this report to track the portion of separating service members who were ever deployed over time.

Table 2-4 contains definitions of Veteran and VA patient in the nationally representative survey data used in the analyses in this report. The two VA surveys (NSV and SoE) and VA administrative data (VA encounter, VA enrollment) define the two terms according to the legal definition described above. The DoD administrative data (MHS TRICARE, Active Duty Master and Loss files, and Contingency Tracking System) are designed around service members and therefore do not explicitly contain Veteran and VA patient data. We define Veterans in these data to mean those who have separated from the military after serving two or more years, and for reservists, a period of activation of 30 days or more is required. We do not exclude former service members who received other-than-honorable discharges.

Table 2-4. Survey Definitions of Veteran and VA Patient

Data File	Veteran	VA Patient
MEPS	Self-report of being honorably discharged by the military	Respondents who had any payment by VA for services used
NHIS	Self-report of having served in active military duty	N/A
BRFSS	Self-report of having ever served in active military duty	N/A
ACS	Once an individual has ceased to "ever serve on active duty in the U.S. Armed Forces, military Reserves or National Guard. Active duty does not include training for the Reserves or National Guard, but does include activation, for example, for the Persian Gulf War"	N/A
NSV	VA definition	VA definition

3 Current and Future Demographics of the Veteran Population

3.1 Introduction

Although many national surveys collect information on Veterans, there has not been a full national accounting of all Veterans since the 2000 Census. This section presents estimates of the number of Veterans and their demographic characteristics. Motivated directly by the language of the Veterans Choice Act, this section describes the current population of Veterans in the United States, categorizes them according to age, sex, race/ethnicity, service cohort, and geographic location, and projects how this population will change by 2024. These estimates are intended to be informative in their own right, as well as to support analyses in Section 4 to predict VA enrollment, in Section 5 to predict health care needs, and in Section 6 to conduct scenario testing.

The team derived these estimates using standard demographic techniques. We estimated the national population using cohort component population projection methods, and estimated migration flows using gravity models. Cohort component population projection is a method that estimates future population sizes by applying mortality rates specific to age, sex, and race/ethnicity to a baseline population. The projection method also accounted for new Veterans entering the population as they leave the military throughout the projection period, and applied the same mortality rates to them moving forward. The team used data from DoD to determine the number and characteristics of new Veterans entering the population from 2000 to 2014. The team further assumed that total military end-strength would decline and that there would be no significant new conflicts over the projection period.[16] The analysis used data from the U.S. Census Bureau to initially distribute our 2013 national projections, then used gravity models to estimate the migration flows of Veterans through 2024.[17] For complete details of the methods used to derive the population projections, see Appendix A.

This section defines *Veteran* according to information available in the ACS and DoD data. ACS characterizes Veterans as those who "ever served on active duty in the U.S. Armed Forces, military Reserves or National Guard. Active duty does not include training for the Reserves or National Guard, but does include activation, for example, for the Persian Gulf War." Once individuals have ceased to serve on active duty in any of these capacities, they are considered Veterans for the purposes of the projections. Note that ACS does not have information on length of service (only eras of active duty) or on status of discharge. Thus, not all Veterans in the projection exercise may qualify for VA services. For example, Veterans who served less than two years or Veterans with "bad paper" discharges (dishonorable, other-than-honorable, and bad conduct discharges) are all ineligible for VA services but are included in the definition of Veteran in this section. Additionally, in projections of future Veteran counts, DoD separation

---

[16] Refer to Section 6 for more discussion on how future conflicts would affect these results.

[17] Gravity models are statistical models of migration that take into account a variety of factors, including age, sex, race/ethnicity, service era, population size of sending and receiving areas, and distance between areas.

data were used to identify individuals who separate from the military. Here, because personnel files were used, we were able to account for years served and whether an individual deployed during his or her time in service.

Overview of Methods and Data for Demographic Analysis

- We estimated the 2014 and 2024 population of U.S. Veterans using a cohort component population projection method.
- Data for this analysis came from the U.S. Census for baseline national projections; we then factored in estimates of mortality, adjusted for demographic characteristics, and added data from DoD on Veterans entering the population.
- We estimated migration flows of Veterans using gravity models.
- Supplementary data came from ACS and accounted for a variety of factors, including age, sex, race/ethnicity, service era, population size of sending and receiving areas, and distance between areas.
- For complete details of the methods used to derive the population projections, see Appendix A.

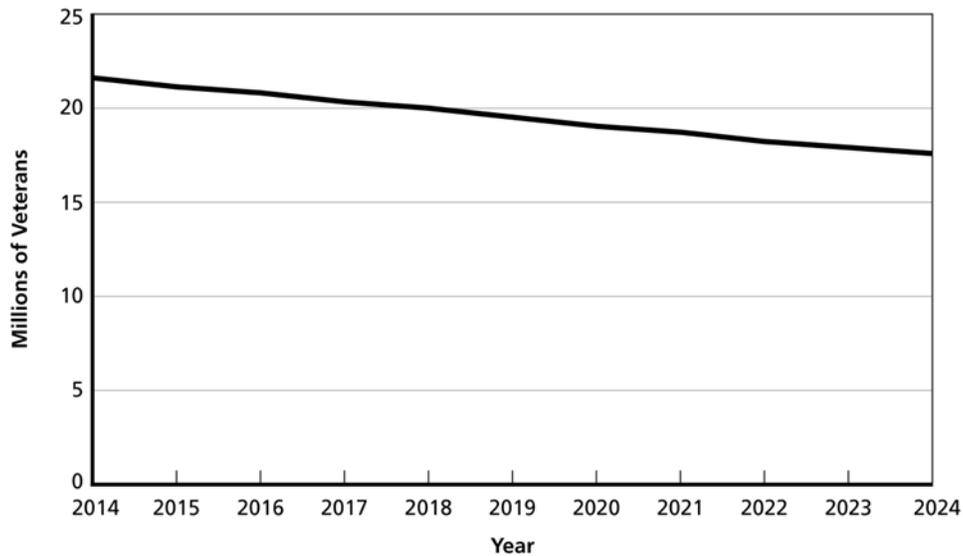
3.2 Results: The U.S. Veteran Population, 2014 and 2024[18]

3.2.1 Total Population

We estimate that the U.S. Veteran population will shrink over the next decade—declining from 21.6 million in 2014 to 17.5 million by 2024, a 19-percent decrease (Figure 3-1). Over a longer time frame, VA estimates that the total number of Veterans will continue to decline, by 37 percent between 2008 and 2033 (U.S. Government Accountability Office, 2009) due to the continued aging of the Veteran population and military downsizing. This projected decrease suggests that in 2032, there will be fewer than 15 million living Veterans (McGeary et al., 2007). Detailed comparisons with VA estimates are discussed in Appendix A.

---

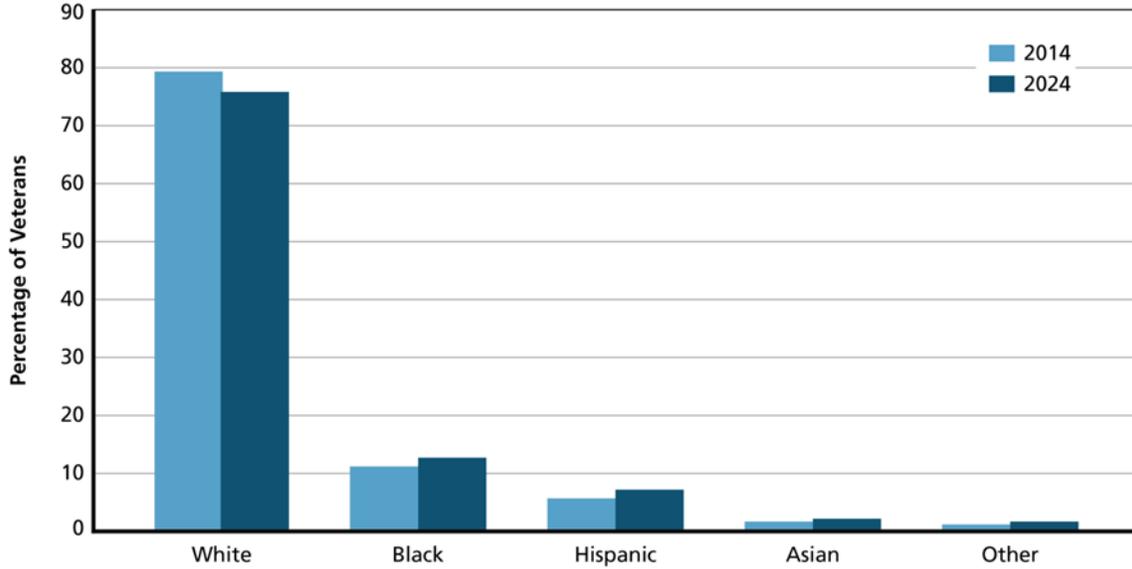
[18] Detailed tables and figures are presented in Appendix 3-B. Here we highlight the main features of the results.

Figure 3-1. Projected Veteran Population, 2014–2024


SOURCE: RAND analysis of VA, DoD, and Census data.

3.2.2 Race/Ethnicity

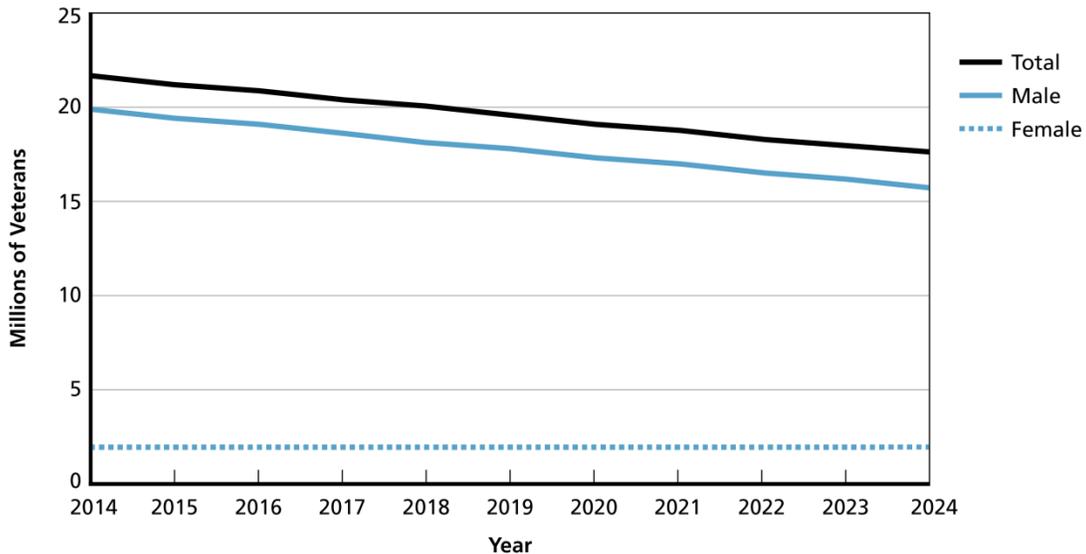
We estimate that the proportion of Veterans who are non-Hispanic white will decline slightly, from 80 percent in 2014 to 76 percent by 2024. The literature shows that the racial and ethnic composition of the Veteran population varies by age. Older Veterans are primarily non-Hispanic white, while younger Veterans are more likely to be racially and ethnically diverse (Lee & Beckhusen, 2012). Gulf War-era Veterans are more racially and ethnically diverse than prior cohorts of Veterans (Holder, 2014). In 2012, minorities accounted for 20 percent of the male Veteran population and 38 percent of male non-Veterans (National Center for Veterans Analysis and Statistics, 2014c). Among Veterans, the two largest minority groups were Veterans who were black or Hispanic (National Center for Veterans Analysis and Statistics, 2011a, 2014a). Figure 3-2 shows our estimates of the racial and ethnic composition of the Veteran population in 2014 and in 2024. Like VA, we estimate that the largest minority groups represented in the Veteran population are Veterans who are black or Hispanic.

Figure 3-2. Race/Ethnicity Composition of the Veteran Population, 2014 and 2024 (Projected)


SOURCE: RAND analysis of VA, DoD, and Census data.

3.2.3 Sex

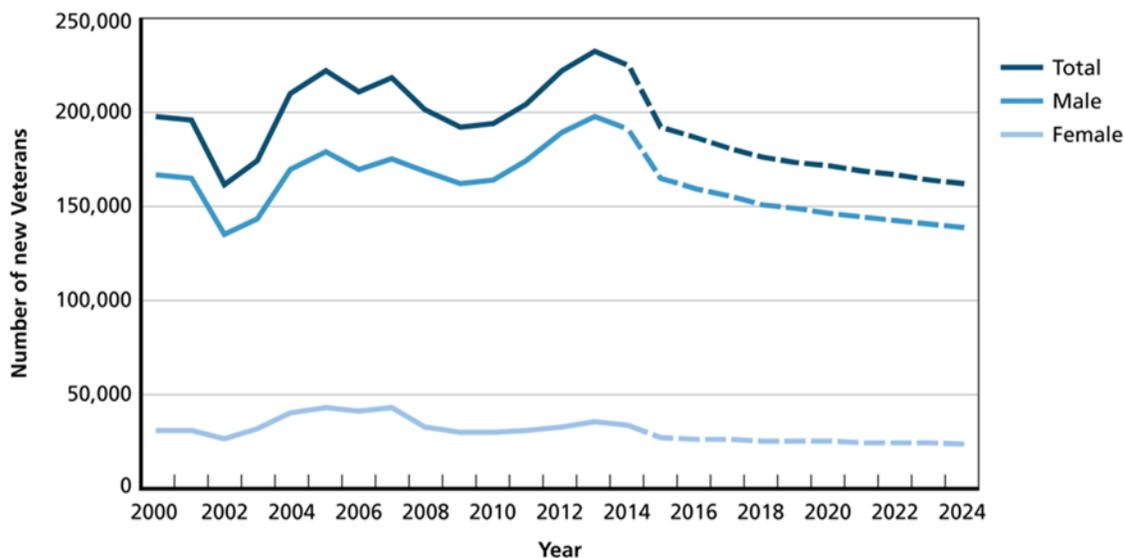
We estimate that the proportion of male Veterans will decline from 92 percent to 89 percent by 2024. Based on the growth trend observed since 2000, the total number of female Veterans is projected to increase very slightly at the same time (Figure 3-3), leading to a 38-percent increase in the relative share of female Veterans, from 8 percent to 11 percent of the Veteran population by 2024. Despite this increase, the Veteran population remains predominately male throughout the projection period.

Figure 3-3. Total Veteran Population by Sex, 2014–2024 (Projected)


SOURCE: RAND analysis of VA, DoD, and Census data.

Our estimates are in line with the existing literature on this topic, which confirms that the majority of Veterans will continue to be men, but the proportion of women is growing (U.S. Government Accountability Office, 2009). In 2008, 15 percent of active duty military and 7.7 percent (1.8 million) of Veterans were women (National Center for Veterans Analysis and Statistics, 2011a; U.S. Census Bureau, 2014). Approximately 33 percent of female Veterans were minorities in 2012 (National Center for Veterans Analysis and Statistics, 2014a). Female Veterans were more likely than non-Veterans to be non-Hispanic black (19 percent versus 12 percent) or non-Hispanic white (69 percent versus 67 percent) (National Center for Veterans Analysis and Statistics, 2011a).

In Figure 3-4, we display the number of new service members who separate from the active component to become Veterans. We estimate that the total number of new Veterans will decrease from approximately 192,000 in 2015 to 162,000 in 2024. The decrease in the total number of new Veterans is driven mostly by separations of male service members, down from 164,000 in 2015 to 138,000 in 2024. We note that new Veterans from the active component represented approximately 1 percent of all Veterans in 2014 (roughly 224,000 out of 21.6 million).

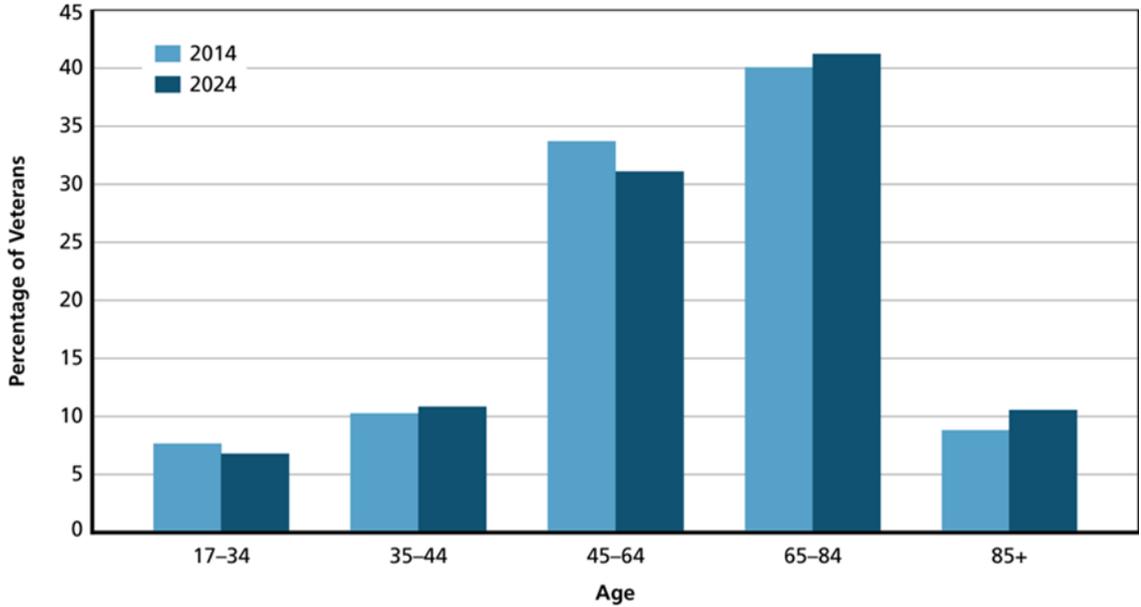
Figure 3-4. Number of New Veterans from Active Component, Total and by Sex


SOURCE: RAND analysis of DoD data.

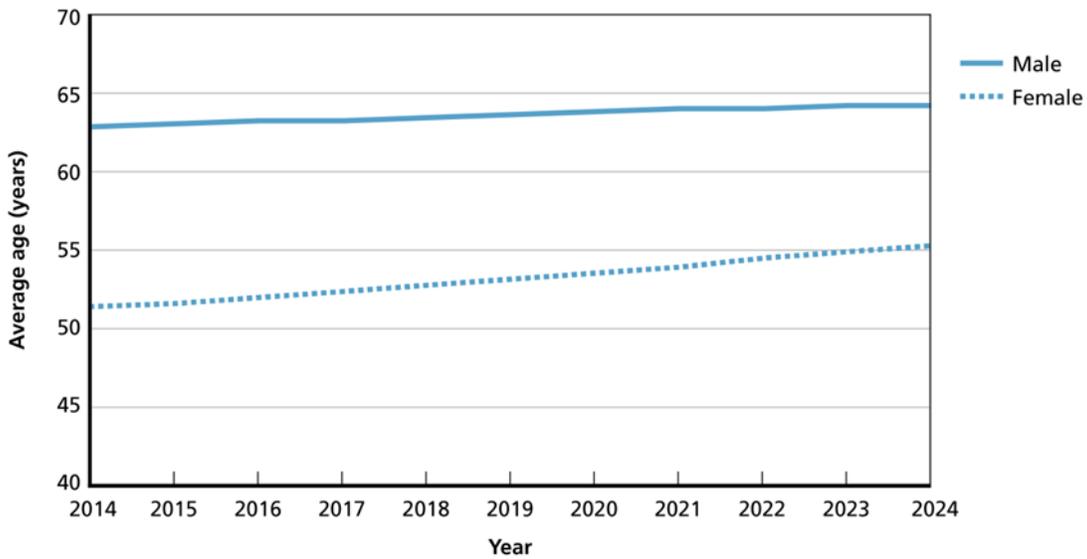
3.2.4 Age

We estimate that the age structure of Veterans will shift between 2014 and 2024, as shown in Figure 3-5. We estimate that the share of Veterans ages 45–64 will decline from 34 percent to 31 percent of the Veteran population, while the share of both younger and older Veterans will increase; the share of Veterans age 65+ will increase from 49 percent to 51 percent by 2024; and the share of all Veterans at the oldest ages (85+) will increase from 9 percent to 10 percent. As shown in Figure 3-6, Veterans' mean age will increase slowly throughout the period. Male Veterans' mean age will rise much more slowly than female Veterans' mean age, although

female Veterans are substantially younger than male Veterans overall, and will continue to be so during the projection period.

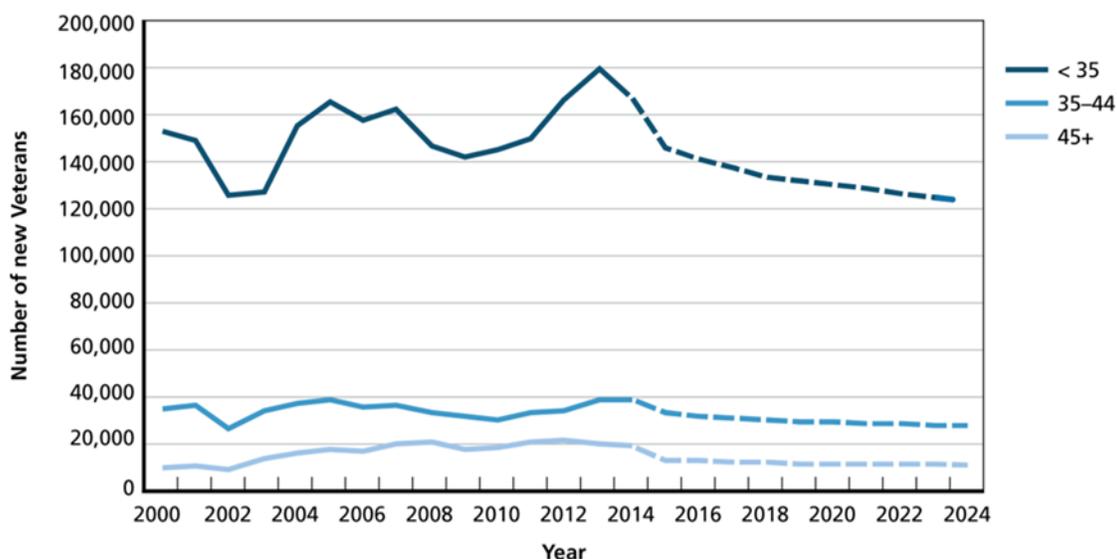
Figure 3-5. Age Structure, 2014 and 2024 (Projected)


SOURCE: RAND analysis of VA, DoD, and Census data.
NOTE: Population in 2014: 21.6 million. Population in 2024: 17.5 million.

Figure 3-6. Mean Age by Sex, 2014–2024 (Projected)


SOURCE: RAND analysis of VA, DoD, and Census data.

We also examined the age profile of newly separated active component service members and plot the results in Figure 3-7. While the number of service members who are projected to separate between 2015 and 2024 is relatively constant for those in age groups 35–44 and 45+, the number of new Veterans under age 35 is expected to decrease throughout the 10-year projection horizon. In 2015, we estimate that 146,000 new Veterans will be under age 35, and that number is expected to decrease to 123,000 by 2024.

Figure 3-7. Number of New Veterans from Active Component, by Age


SOURCE: RAND analysis of DoD data.

A profile of the current age structure shows that in 2014, the largest conflict-era cohort—Vietnam-era Veterans—averaged 67 years of age, while the second-largest conflict-era cohort—Gulf War-era Veterans—averaged 47 years of age (see Table 3-1).

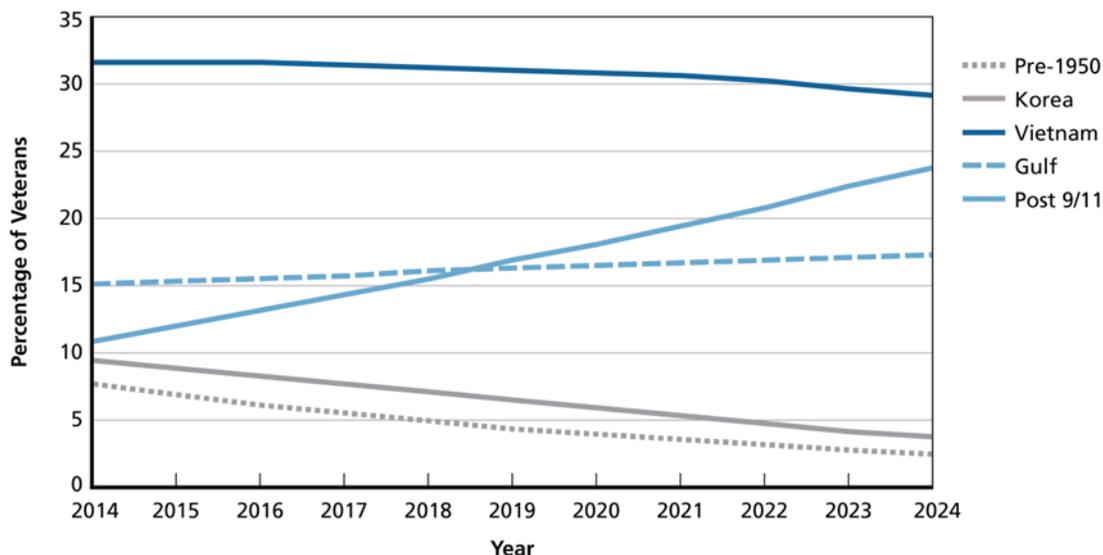
Table 3-1. Number and Mean Age of Veterans, by Era of Service (2014)

Era of Service	Mean Age	Veterans (millions)
Pre-1950	86	1.6
Korean conflict	82	2.0
Pre-Vietnam peace	75	2.1
Vietnam	67	6.7
Post-Vietnam peace	53	3.3
Gulf War	47	3.2
Post-9/11	36	2.6

SOURCE: RAND analysis of VA, DoD, and Census data.
NOTE: Individuals are grouped into the most recent active duty wartime era they served in (if they report multiple periods of service), or if they only served during peacetime, they are grouped into their most recent peacetime era.

3.2.5 Service Cohort

The team estimates that pre-Vietnam-era Veterans constituted 25 percent of the total Veteran population in 2014, but by 2024, their share is projected to fall to 13 percent of the total. The analysis also estimates that the share of Vietnam-era Veterans (1964–1975) will decline slightly from 32 percent to 29 percent of the Veteran population by 2024. These estimates are consistent with earlier numbers; in 2000, Vietnam-era Veterans were estimated to account for 31.7 percent of the Veteran population (Richardson & Waldrop, 2003). The RAND projection estimates that the proportion of Gulf War-era and post-9/11-era Veterans will grow from 26 percent to 41 percent of the total Veteran population by 2024; post-9/11 Veterans alone will account for 24 percent of all Veterans in 2024. Figure 3-8 presents the projected service-era cohort composition changes in the Veteran population over time (pre- and post-Vietnam peacetime-only service eras are not presented), highlighting the rapid proportional growth of the post-9/11 era.

Figure 3-8. Conflict-Era Veterans as Percentage of Total Veteran Population, 2014–2024 (Projected)


SOURCE: RAND analysis of VA, DoD, and Census data.

3.2.6 Socioeconomic Status

3.2.6.1 Employment

Educational and economic measures are routinely considered in the examination of demographic events and processes (O'Hare, Pollard and Ritualo, 2004). Our review of the literature found that in 2014, approximately 5 percent of Veterans were unemployed compared with 6 percent of non-Veterans (Bureau of Labor Statistics, 2015). There was notable variation in unemployment by service era. Approximately 7 percent of Veterans who deployed to Afghanistan and Iraq were unemployed in 2014 (Bureau of Labor Statistics, 2015). In 2014, there were approximately 573,000 unemployed Veterans (Bureau of Labor Statistics, 2015). The majority of the unemployed Veterans (59 percent) were age 45 or older (Bureau of Labor Statistics, 2015). Comparisons between Veterans and civilians that account for disability status show that Veteran status and being female are associated with higher rates of unemployment, though disability is the strongest predictor of being unemployed (Smith, 2014).

In Table 3-2, we present data on the socioeconomic status of the Veteran and non-Veteran civilian populations using ACS data from 2009 to 2013. The data in the table are interpreted as the mean throughout the 2009–2013 period.[19] According to ACS, unemployment was lower for Veteran than non-Veteran civilians, but it was slightly higher throughout this period than the level reported by the Bureau of Labor Statistics. The table also indicates that Veterans tend to

---

[19] ACS estimates are period estimates; when precision of estimates is more important than currency of estimates, the U.S. Census Bureau recommends using the five-year ACS estimates rather than the one-year estimates. Thus, we rely on the five-year ACS estimates throughout this section. See Beaghen & Weidman, 2008.

---

have higher incomes and education levels than their non-Veteran counterparts. Both male and female Veterans have higher average personal incomes than non-Veterans, and female Veterans have higher average family incomes than non-Veterans. Male Veterans, however, report lower average total family incomes than their non-Veteran civilian male counterparts. For both sexes, Veterans are less likely to live below the poverty line than non-Veterans, and more likely to have graduated from high school. Relative to non-Veterans, Veterans are also more likely to have at least a college degree. Characteristics of Veterans with VA medical insurance are also presented;[20] unemployment is higher, and income is lower, as expected by design.

Table 3-2. Socioeconomic Characteristics of the Veteran and Non-Veteran Civilian Population, by Sex, 2009–2013

Socioeconomic Characteristics	Non-Veteran Civilians		Veterans		Veterans with VA Insurance	
	Female	**Male**	**Female**	**Male**	**Female**	**Male**
% unemployed	9.07	10.26	8.30	8.43	12.15	12.58
Avg. total family income	$86,335	$92,117	$89,547	$87,533	$79,576	$73,717
Avg. total personal income	$27,113	$44,456	$38,304	$50,964	$35,775	$41,514
% income < 100% FPL	15.25	12.94	9.98	6.63	12.33	8.52
% income 100–250% FPL	27.38	25.87	24.25	23.50	28.52	29.77
% income 250–400% FPL	21.32	21.92	23.85	24.68	24.30	25.71
% income > 400% FPL	36.05	39.27	41.92	45.19	34.84	36.00
% Less than high school	14.81	18.51	2.41	8.05	2.45	9.57
% HS graduate or GED	27.47	28.29	19.07	30.50	16.81	30.98
% Some college	23.85	21.69	31.60	27.43	32.65	29.11
% College +	33.86	31.51	46.92	34.02	48.09	30.34
% With medical insurance	84.90	77.24	92.62	94.15	100.00	100.00

SOURCE: RAND analysis of Census data.
NOTES: All Veteran means are statistically different (at p < 0.001) from non-Veteran civilian means by sex. Unemployment does not include those who are not in the labor force (e.g., retired).
FPL = federal poverty level, which varies by size of the household.

3.2.6.2 Income

Corresponding to the analysis described above, the literature also suggests that Veterans are less likely to live below the poverty line than non-Veterans, and that Veterans have higher median incomes (2000, 2009, 2012) (National Center for Veterans Analysis and Statistics, 2011c, 2014a, 2014d). Veterans working full-time had higher median earnings and personal incomes than non-Veterans in 2012 (National Center for Veterans Analysis and Statistics, 2014c). Compared with male Veterans, female Veterans are more likely to have no health

---

[20] Individuals' insurance status is reported by the primary householder responding to the ACS survey, who responds on behalf of all members of the household.

---

insurance coverage, have no income, and live in poverty (National Center for Veterans Analysis and Statistics, 2014d). VA patients are more likely to have a lower household income compared with non-patients. However, these differences are not surprising, given that eligibility for VA care is partly dependent on income (National Center for Veterans Analysis and Statistics, 2014e).

3.2.6.3 Homelessness

In 2010, Veterans accounted for approximately 10 percent of the adult population; however, they represented a disproportionate share of the homeless adult (16 percent) and sheltered homeless adult (13 percent) populations (National Center for Veterans Analysis and Statistics, 2012b). Approximately 10 percent of homeless Veterans are women (U.S. Department of Housing and Urban Development, 2014), and female Veterans are three to four times more likely than non-Veteran women to become homeless (Washington et al., 2010). Among female Veterans, sexual assault during military service, unemployment, disability, and poor physical and mental health are associated with being homeless (Washington et al., 2010). While homelessness is a significant problem among the Veteran population, the total size of the homeless Veteran population has decreased over time. The U.S. Department of Housing and Urban Development reported that there were 49,933 homeless Veterans in 2014, representing less than 0.25 percent of the total Veteran population. Between 2010 and 2014, the number of homeless Veterans declined by 33 percent (U.S. Department of Housing and Urban Development, 2014).

3.2.7 Geographic Distribution of Veterans

This section presents a series of maps that show the geographic distribution of the U.S. Veteran population by a variety of characteristics, and how this distribution is expected to change between 2014 and 2024. Understanding the geographic distribution of Veterans is an important consideration for policies that attempt to align the availability of health care services with the Veteran population. The maps on each topic are paired: The first of the two presents information for 2014, and the second presents information for 2024. We report geographic detail using Public Use Microdata Areas (PUMAs), which are geographic units used by the U.S. Census Bureau. Typically, each PUMA contains roughly 100,000 residents. PUMAs respect state borders, but not necessarily county or municipality borders. We provide more-complete information on PUMAs in Appendix A.

Each map shading indicates the total number of Veterans living in all PUMAs within 40 miles of the center of the shaded PUMA.[21] The text in the lower left corner reports the total number of Veterans depicted in the map, as well as the percentage of the total Veteran population they represent. The bar chart on the lower right serves the dual purpose of reporting how each shade corresponds to the number of Veterans, as well as what portion of the depicted population lives in the PUMA shaded with each color.

---

[21] For an explanation of why we shaded based on all Veterans living *near* each PUMA rather than just those living *in* each PUMA, please see Appendix A.

3.2.7.1 Geographic Concentration of Veterans

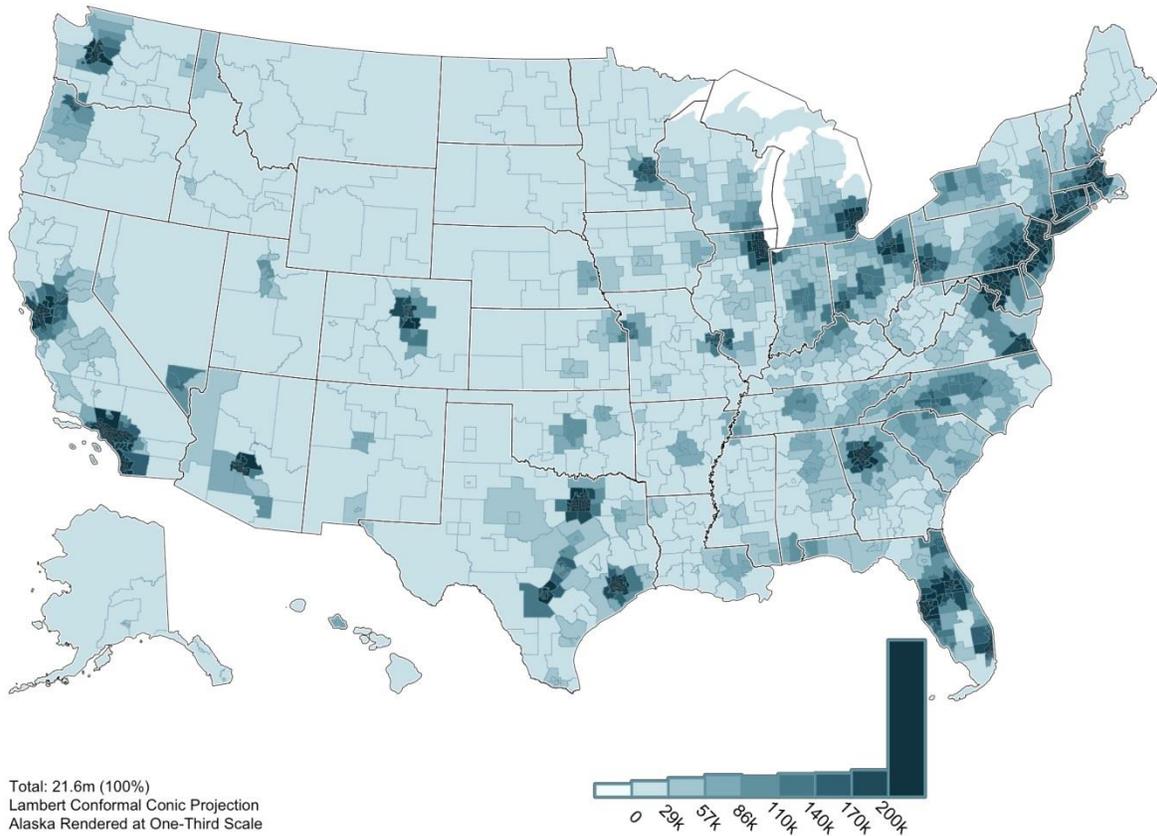
Figure 3-9 depicts the geographic distribution of the Veteran population as a whole in 2014. Like the U.S. population as a whole, the majority of Veterans are concentrated in a small number of heavily urbanized regions. The "Bos-Wash" corridor, a stretch of heavily urbanized area that runs from Boston, Massachusetts, to Washington, D.C., contains 30–50 million people and 1.43 million Veterans.[22] Southern California, including the Los Angeles, Riverside, and San Diego metropolitan areas, contains more than 20.97 million people and 1 million Veterans. Other large cities, such as Chicago (population: 9.55m, Veterans: 423k), Dallas (6.95m, 360k), Houston (6.49m, 332k), Atlanta (5.61m, 405k), Miami (5.93m, 262k), and the San Francisco Bay Area (6.55m, 346k), account for another 41.08 million people, including 2.08 million Veterans. Taken together, these eight urbanized regions account for 35 percent of the American population and 20 percent of the Veteran population.

Of the 318.9 million people residing in the United States in 2014, 21.6 million, or 6.8 percent, were Veterans. Slightly more Veterans than expected based on this national average live in Virginia Beach (14 percent), Boston (14 percent), central Florida (10 percent), Cleveland (10 percent), Washington, D.C. (9 percent), and San Antonio (9 percent). Slightly fewer Veterans than expected live in Chicago (4 percent), Miami (4 percent), Dallas (5 percent), Los Angeles (5 percent), Houston (5 percent), San Francisco (5 percent), Minneapolis (5 percent), and New York City (3 percent).

---

[22] Veteran estimates include all Veterans living in a PUMA within 40 miles of the named city centers. Total population estimates include the entire metropolitan population, not just the population of the named cities proper.

Figure 3-9. Total Veteran Population in 2014

Total: 21.6m (100%)
Lambert Conformal Conic Projection
Alaska Rendered at One-Third Scale


SOURCE: RAND analysis of VA, DoD, and Census data.

Figure 3-10 displays how the Veteran population is expected to look in 2024. Overall, we expect the population to decline to 17.5 million as older cohorts of Veterans experience high rates of age-related mortality. For the most part, these losses will not change the geographic distribution of Veterans. However, we estimate that the share of Veterans in the Ohio River Valley cities, including Buffalo, Cincinnati, Cleveland, Columbus, Detroit, Indianapolis, and Pittsburgh, will decline.

SOURCE: RAND analysis of VA, DoD, and Census data.

3.2.7.2 Age Patterns in Geographic Distribution

Over time, there will be more diversity in the geographic distribution of Veterans by age. Veteran mean age will grow older over time, but the increases in the proportion of Veterans at both the younger and older ages will alter the geographic distribution of Veterans by age. We estimate that Veterans under age 35 will be concentrated in areas surrounding Los Angeles; Dallas; Washington, D.C.; and northern New Jersey by 2024. Over time, Veterans under age 35 will constitute a greater proportion of the population in Northern California, central Washington state, the Midwest, and Wyoming and Utah. Other portions of the Southwest and much of the Southeastern seaboard, from Virginia Beach through the coast of Georgia, will see a decrease in the proportion of the population that is under age 35. See Figures 3-11 and 3-12.

Figure 3-11. Total Veterans Under Age 35, 2014

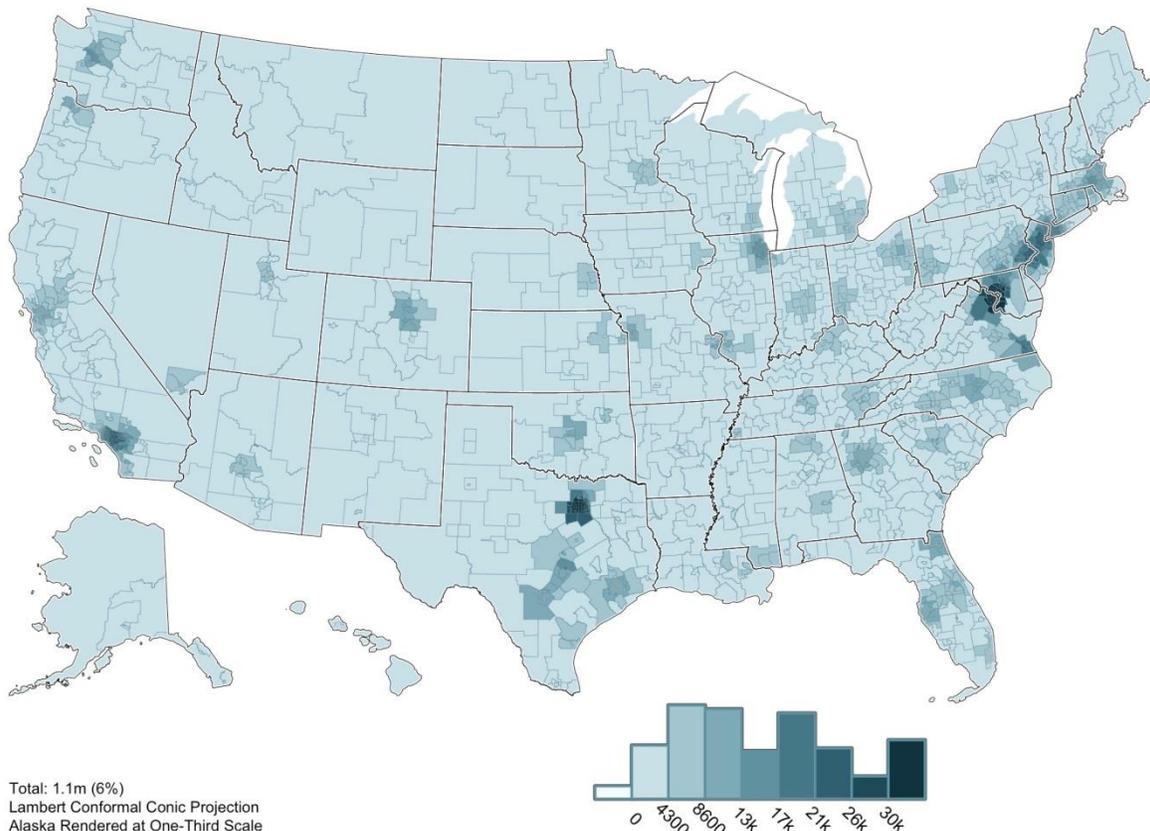
Figure 3-12. Total Veterans Under Age 35, 2024 (Projected)

Total: 1.1m (6%)
Lambert Conformal Conic Projection
Alaska Rendered at One-Third Scale


SOURCE: RAND analysis of VA, DoD, and Census data.

Concentration of older Veterans in areas of current higher prevalence will continue to 2024 (see Figures 3-13 and 3-14). San Francisco; Los Angeles; Denver; southwestern Texas; much of Florida; Washington, D.C.; western Pennsylvania; northern New Jersey; New York City; and western Massachusetts are currently places in which the share of older Veterans is high, and they are predicted to remain high through 2024. At the same time, we estimate that the share of older Veterans living in much of the Northeast and Florida (especially the panhandle), the Midwest, Wyoming, Utah, and southwestern Alabama will decline.

Trends in geographic distribution by age are likely to reflect cohort changes in where Veterans reside, rather than trends in migration per se. Areas where older Veterans decline in proportion are most likely to be areas where they are not being replaced by incoming cohorts of Veterans. Similarly, areas with proportionate growth in Veterans over age 65 are likely areas where currently middle-aged Veterans live and will continue to live as they age. Florida is an exception to this, as older Veterans will also tend to migrate there (although in relatively low numbers in comparison with the local populations). See Section 3.2.9 for more details.

3.2.7.3 The Changing Urban-Rural Distribution

Over time, fewer Veterans are going to be located in rural areas,[23] reflecting both the overall national population trend of movement away from rural areas and absence of younger Veterans replacing older rural Veterans. However, northwestern Washington state, a belt running through Montana to Wisconsin, parts of Northern Michigan, much of Maine, Alaska, and northern Texas (Amarillo outskirts) will remain areas of rural Veteran populations by 2024. See Figures 3-15 and 3-16.

---

[23] Rural status is based on rural-urban commuting area codes, which are based on measures of population density, urbanization, and daily commuting from the 2010 Census and 2006–2010 ACS. Our analysis assumes that the classifications will remain the same in 2024 as in 2014, and thus the 2024 maps may be best interpreted as "based on areas that were rural in 2014." Refer to the U.S. Department of Agriculture Economic Research Service for more information on rural-urban commuting area codes (U.S. Department of Agriculture, 2014).

3.2.8 Distance to Nearest Veteran Facility

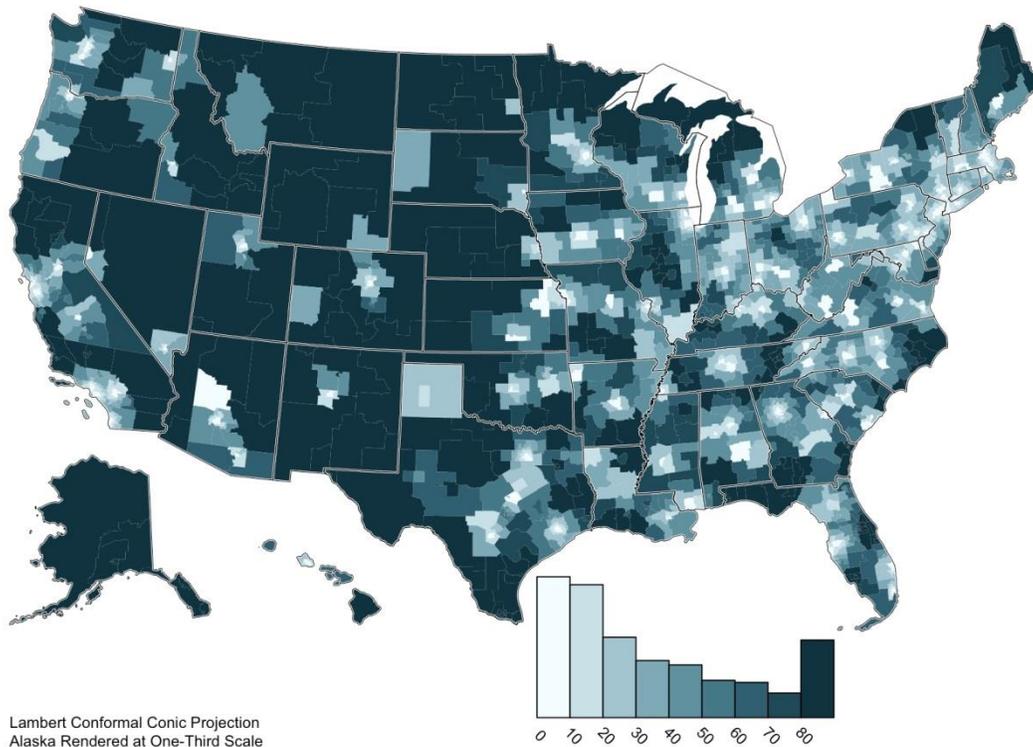
The VA medical system relies primarily on two kinds of facilities: VAMCs and CBOCs. VAMCs are full-service medical centers, offering both primary care and specialty care. CBOCs are satellite clinics that provide primary, preventative, and behavioral health services. While VAMCs are the heart of the system, CBOCs provide a cost-effective way to increase access to basic services in rural areas, reduce travel time to primary care services, and serve as a flexible option for adapting to changes in demand for VA services.

3.2.8.1 VA Medical Centers

Figure 3-17 displays the straight-line distance from the center of each PUMA to the nearest VAMC. In general, VAMCs are more prevalent and closer spaced in the Northeast, and most Veterans live within a relatively short distance of their nearest facility. However, coverage is uneven by region, especially the more sparsely populated noncoastal Western states.

Figure 3-17. Distance to Nearest VA Medical Center (miles), 2014

Lambert Conformal Conic Projection
Alaska Rendered at One-Third Scale

0 10 20 30 40 50 60 70 80


SOURCE: RAND analysis of VA, DoD, and Census data.

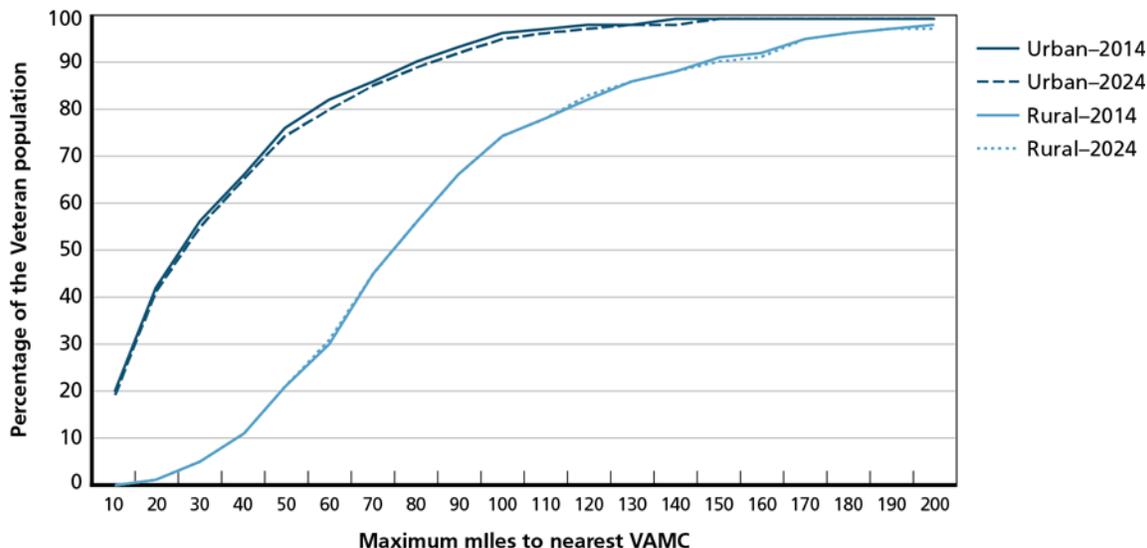
Figure 3-18 shows the percentages of the Veteran population living in PUMAs within a given distance of the nearest VAMC in 2014, for Veterans living in urban and rural areas. Figure 3-19 shows the same for Veterans by region. The darker lines indicate the percentage of the Veteran population living in urban areas, while the lighter lines indicate the percentage of Veterans living in rural areas. The solid lines report the percentages for 2014, while the dashed lines indicate the percentages for 2024, based on our projections.

In 2014, 70 percent of the urban Veteran population live within 40 miles of the nearest VAMC, and 90 percent live within 80 miles. By 2024, this distribution is projected to change relatively little, with perhaps a 1–2 percentage point increase in those living farther away from the nearest VAMC.

As expected, the rural Veteran population tends to be much farther from the nearest VAMC. While more than 70 percent of urban Veterans live within 40 miles of a VAMC, less than 20 percent of rural Veterans do. The differences persist when we consider a much wider radius. While nearly all urban Veterans live within 100 miles of a VAMC, less than 80 percent of rural Veterans live within a similar radius. Many of these Veterans live in relatively remote areas. Just

---

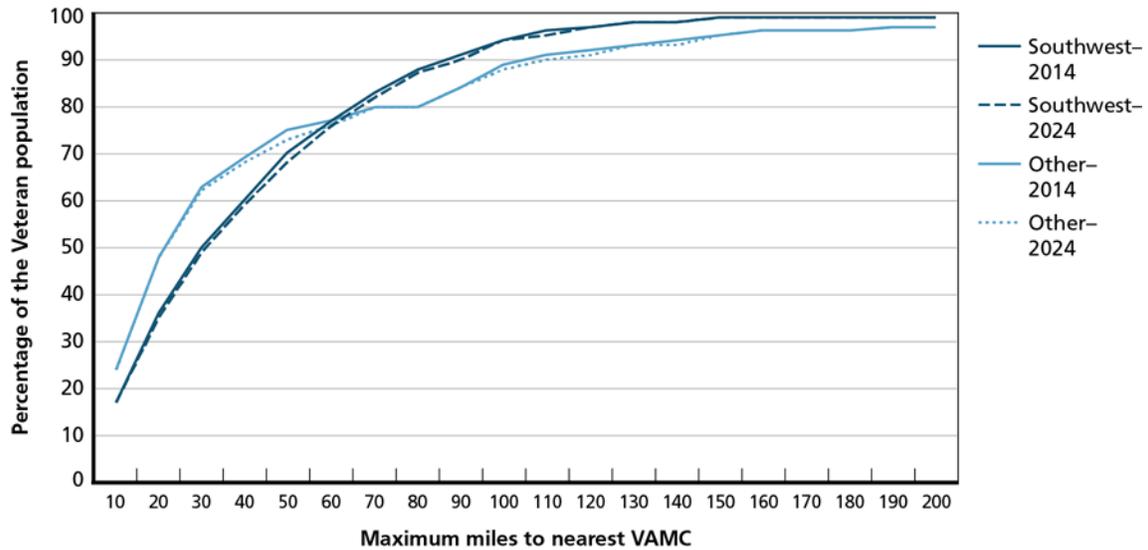
under 40 percent live more than 200 miles from the nearest large (> 2 million) city—mostly in the Great Plains and the Southwest.

Figure 3-18. Percentage of Veterans Living Within a Given Distance of a VAMC, by Urban/Rural Status


For the most part, the urban Veteran population is projected to stay closely aligned with the location of current VAMC and population distribution. However, the Veteran population in the Southwest has the most uneven alignment and most risk of future misalignment. In 2014, 10 percent more Southwestern Veterans lived within 40 miles of a VAMC, but 10 percent less lived within 75 miles. By 2024, the situation is not projected to improve. The Southwest has witnessed particularly strong population growth rates in recent decades, including growth in the Veteran segments. New centers of population have emerged, and the construction of VAMCs has not yet caught up. Moreover, because VAMCs in the Southwest are far more widely spaced apart, emerging population centers in the Southwest are less likely to fall within a short distance of an existing facility, and less likely to have an alternative VAMC in proximity.[24] This combination of factors—above-average rates of population change and wider spacing of VA facilities—places Southwestern VAMCs at higher risk of becoming geographically misaligned with the Veteran population.

---

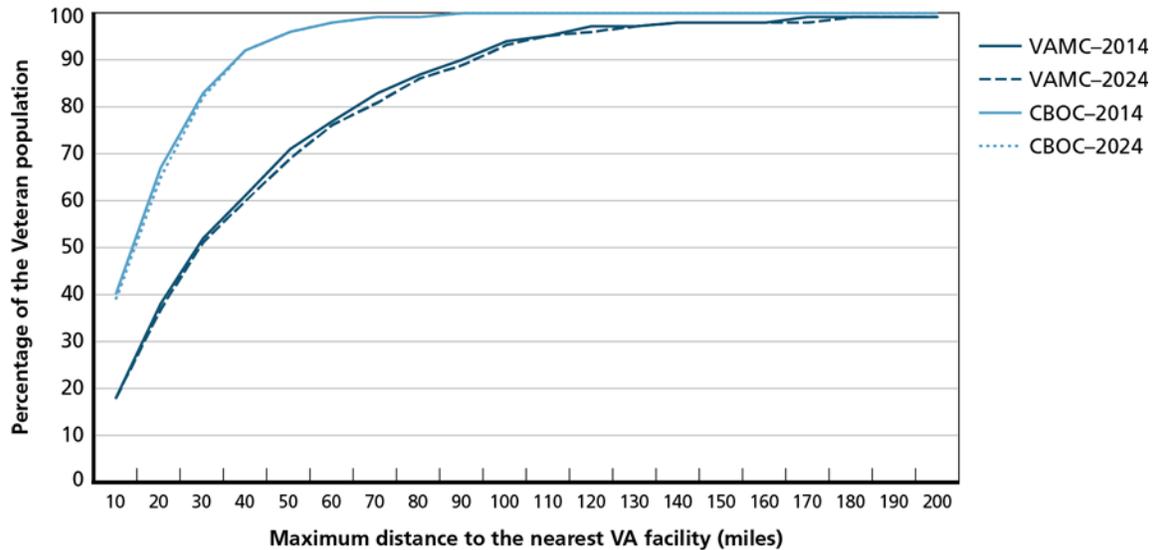
[24] This is in marked contrast to the Ohio River Valley region. The Ohio River Valley is also experiencing significant shifts in the distribution of the population, but spacing of VAMCs generally means that emerging population centers still fall within a short distance of the a facility.

Figure 3-19. Percentage of Veterans Living Within a Given Distance of a VAMC, by Region


3.2.8.2 Community-Based Outpatient Clinics

Figure 3-20 charts the percentage of the Veteran population living in PUMAs within a given radius from different types of VA facilities. While VAMCs offer a wide array of medical services, CBOCs offer the most commonly used basic services—primary, preventive, and counseling services. The darker line reports the maximum distance to the nearest VAMC, while the lighter line reports the equivalent statistics for the nearest CBOC.

More than 90 percent of all Veterans live in a PUMA that falls within 40 miles of a CBOC, compared with just under 70 percent for a VAMC. Because of the wider geographic coverage of the CBOC network, this pattern is unlikely to change by 2024, despite projected change in the distribution of the Veteran population. That is, while Veterans may be closest to a different set of CBOCs in 2024, they will still be relatively close to a CBOC.

Figure 3-20. Percentage of Veterans Living Within a Given Distance of the Nearest VA Facility, VAMC Versus CBOC


3.2.9 Veteran Net Migration

Veterans, like other civilians, move around the country for work, family, retirement, and many other reasons.[25] In order to inform projections of where Veterans will live over the next 10 years, it is important to consider their migration patterns throughout the entire period. We estimated net migration for each year between 2014 and 2024 based on predicted in-migration and out-migration rates from gravity models, which utilized information on sex, service era, age, race/ethnicity, distance between PUMAs, and population of Veterans in areas of origin and destination to estimate the number of migrants. Results suggest that men are less likely to migrate than women, consistent with migration trends in the national population, according to ACS and other data sources. Previous research has linked greater female residential mobility and desire to move to greater residential satisfaction (Mateyka, 2012) and notes that women's migration was significantly less affected by the Great Recession than men's (Benetsky & Fields, 2015).[26] All else equal, older Veterans (especially those 70 and older) are more likely to migrate compared with younger Veterans (25–29 age group), likely reflecting retirement moves as in the rest of the civilian population. However, all else equal, Veterans in older service cohorts are less likely to migrate compared with those in the 9/11 era. Thus, within each service cohort, older Veterans are more likely to migrate, especially among the most recent service cohorts. All race/ethnicity groups other than whites are more likely to migrate than whites. Migration is less

---

[25] Here we refer to residential migration, not vacation or other travel.

[26] Mateyka (2012) used data from the Survey of Income and Program Participation, conducted by the U.S. Census Bureau, to identify greater mobility and greater desire to move among women in 2010–2011. Desire to move was measured using the following questions: (1) Are conditions in your home undesirable enough that you would like to move? (2) Overall, is the threat of crime where you live undesirable enough that you would like to move? (3) Is your neighborhood undesirable enough that you would like to move? (4) Are the public services undesirable enough that you would like to move?

---

likely to occur between PUMAs that are farther apart—that is, migration over longer distances is less likely than migration over shorter distances. Longer distances between PUMAs have negative impacts on the likelihood of migrating. The overall net migration rates vary from 2.97 percent in 2014 to 1.61 percent in 2024. Based on ACS data, migration between PUMAs is around 4 percent for the American population, which indicates that Veterans are less likely to migrate than non-Veterans. A previous study about interregional population flows in the United States (Raymer & Rogers, 2007) suggests that migration rates are higher among those between ages 20 and 39, which is related to labor migration. Since only 11.86 percent of Veterans were within this age range in 2014, gravity models suggest that they are more likely to migrate at older, near-retirement ages. Thus, net migration is relatively small and not likely to be a major factor in Veteran demographics. Prior research also suggests that migrating Veterans do not have a noticeable impact on VA health care use (Cowper & Longino, 1992).

It is important to note that this is a discussion of net migration, not in- and out-migration separately (that is, the churn in Veteran residents). Outflows of migrants to areas generally closely match inflows that replace them, resulting in relatively low levels of net migration. It is also important to note that the estimation process does not treat the initial entry of Veterans to the civilian population as migration; in the projection method, Veterans are assumed to initially enter the civilian population according to historical geographic distribution of Veterans with the same age, sex, race/ethnicity, and service-era characteristics, as described in Appendix A. In these projections, migration refers only to movement after the initial entry to the civilian population; we do not include the movement between the initial location of service members when they exit the military and where they are initially distributed as an incoming Veteran. We interpret this type of population change as cohort change, rather than change resulting from migration. In this way, some areas may see relatively increasing populations due to cohort change, but negative net migration (i.e., incoming Veterans may initially locate in Los Angeles, but subsequently move elsewhere).

We used predicted rates from gravity models to estimate net migration. Areas with the highest net migration (the result of in-migrants subtracted by out-migrants at the end of the year) are in Texas, Arizona, Utah, southern Colorado, Wyoming, western Montana, Idaho, Washington state (except the interior), coastal Oregon, Northern California, and northwestern and southwestern Florida. Areas with greater negative net migration are in the interior of Washington state; Southern California; Phoenix, Arizona; San Antonio, Houston, and Dallas, Texas; and Jacksonville, Florida. By 2024, Nevada is also expected to experience general negative net migration, and Southern California will see marginal net in-migration, although net migration overall is low.

3.2.9.1 Net Migration and Presence of VA Facilities

In order to examine the hypothesis that Veterans choose to move to areas where they are closer to VA facilities, we used spatial regression models to examine how growth and movement in the Veteran population is related to the location of a range of VA facilities. Complete details of the estimation methods and results are provided in Appendix A.1.5. Results indicate that in net, migrating Veterans are tending to move farther away from, rather than closer to, VA facilities (VAMCs and CBOCs). This suggests that Veterans' migration decisions are

not strongly driven by the presence of VA facilities, and indeed, that they are choosing to move to areas that are not as well covered with VA facilities. Recall that migration is only a small contributor to how Veterans are distributed around the country; although net migration patterns suggest movement away from VA facilities, this does not mean an overall trend of Veterans being farther from facilities. As Section 3.2.8 describes, overall distance to facilities is not likely to change substantially over the next 10 years.

3.2.9.2 Changing Population Size and VAMC Location

The RAND projections indicate an overall 19-percent decline in the Veteran population over the next decade. While the majority of the country will see shrinking Veteran populations, some areas will lose proportionately more than others, and several areas are projected to see growth in the number of Veterans. For a sense of the regions in which VA facilities will face particularly steep population declines (or growth), and regions without VA facilities that will face growth, see Figure 3-21, which presents the projected percent change in Veteran population size for each PUMA between 2014 and 2024, with VAMC facilities indicated on the map as black dots.

Figure 3-21. Projected Percent Population Change 2014–2024, with VAMC Locations

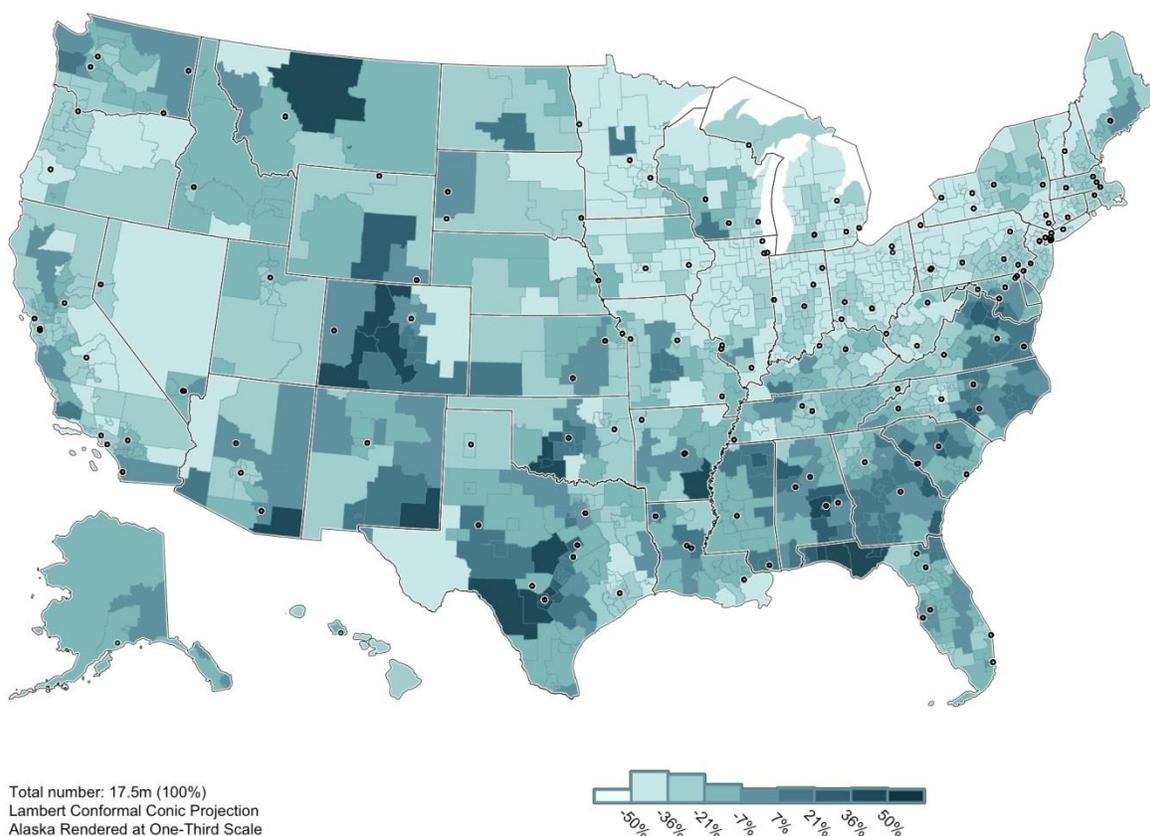
Lambert Conformal Conic Projection
Alaska Rendered at One-Third Scale


SOURCE: RAND analysis of VA, DoD, and Census data.

Population loss is the norm, but the greatest population losses over time are expected in the Ohio River Valley and upper Midwest areas, as well as rural regions of the West. Several regions are expected to see population gains, however. Washington, D.C.; Charlotte, North Carolina; Columbia, South Carolina; Tallahassee/Panama City, Florida; San Antonio and Austin, Texas; and Montgomery, Alabama, are all particularly notable, as population gains are projected for the cities themselves, whereas most other population growth is projected to occur in areas encircling cities.

One implication of the projected population growth is that some of these areas currently do not have local VAMC facilities; growth in Montana, Wyoming, and Colorado occurs where VAMCs do not currently exist. Similarly, growth in the Florida Panhandle is in the absence of any VAMCs. It is important to note that (a) these areas have relatively small Veteran populations to begin with, and that higher percentage growth in these regions may not translate to large absolute increases, and (b) at least part of the growth in the North Dakota, Montana, South Dakota, and Wyoming High Plains region is related to current trends in the shale oil boom that will be sensitive to the economics of oil production. Regardless, the projected growth trends are worth noting, given their relatively stark differences to the overall national population loss trend.

3.3 Summary of Key Findings

The population of U.S. Veterans will decrease by 19 percent over the next 10 years. The Veteran population has been decreasing for more than three decades, and this trend will continue. According to the U.S. Census, in 1970, there were 28.1 million Veterans; in 1990, there were 27.5 million Veterans. We estimate that there were 21.6 million Veterans in 2014. Over the next 10 years, our projections, drawing on Census, VA, and DoD data, show that the Veteran population will decline to 17.5 million. This represents a 19-percent decrease and is in keeping with declines in the size of the total military end-strength since the 1980s. The large cohorts that served prior to the all-volunteer military in 1973 are aging and dying off. The newer Veterans entering the system reflect smaller, all-volunteer service cohorts.

Vietnam Veterans will no longer constitute the largest service cohort by 2024. The share of Vietnam-era Veterans (1964–1975), currently the largest service cohort, will decline slightly from 32 percent of the Veteran population in 2014 to 29 percent by 2024. Pre-Vietnam-era Veterans constituted 25 percent of the total Veteran population in 2014, but by 2024, their share is projected to fall to 13 percent. The proportion of Veterans from the Gulf War and post-9/11 eras will grow from 26 percent in 2014 to 41 percent of the total Veteran population by 2024; post-9/11 Veterans alone will account for 24 percent of Veterans in 2024.

The age mix among Veterans will shift slightly. One consequence of this declining service cohort replacement is that the age mix among Veterans will shift slightly over the next 10 years; Veterans will become somewhat older on average. This is particularly pronounced for female Veterans; male Veterans' average age will rise slightly from 62.8 in 2014 to 64.3 in 2024, while female Veterans' average age will rise from 51.4 to 55.2 over the same period. Middle-age Veterans will decline in share; the share of Veterans ages 45–64 will decline from 34 percent to

---

31 percent of the Veteran population, while the share of both younger and older Veterans will increase.

The racial/ethnic mix will also change modestly. Another consequence of the changing cohort mix will be that the race/ethnic mix of the Veteran population will change modestly. The proportion of Veterans who are non-Hispanic white will decline slightly from 80 percent in 2014 to 76 percent by 2024, while all other race/ethnic groups see slight increases in proportion (with the largest gain among Hispanics).

The Veteran population will become more concentrated in urban areas, and the relative share of the Veteran population in the Ohio River Valley region will diminish. Another consequence of the changing cohort mix will be that the Veteran population will shift away from the largest cities of the Ohio River Valley region, while becoming more concentrated in the major urban centers in other regions. However, migration is less frequent among Veterans than non-Veterans and will not play a substantial role in the geographic distribution of Veterans between 2014 and 2024. While migration rates vary with a range of demographic characteristics, the overall trend is one of slow decline in migration rates generally. VAMC facilities in the Ohio River Valley region will face more-rapid declines in the total Veteran population base they serve than the Southwest region, where our projections suggest that relative Veteran population concentration will not be as well matched in 2024 to existing VAMC locations.

The 2024 projections indicate a 19-percent decline in overall Veteran population. Despite this decline, the 2024 geographic distribution will not be drastically different from the current distribution, and we do not project that overall distance to existing VA facilities will increase substantially. The existing CBOC coverage puts almost all Veterans (92 percent) within 40 miles of some type of VA facility in 2024. However, the total numbers and characteristics of Veterans will change within the overall geographic distribution. Looking forward, it does not necessarily seem to be a matter of building new facilities, but rather anticipating the types of services that will need to be provided at existing VA facilities.

First, in terms of the total Veteran populations to be served there are some anticipated changes to plan for. The Ohio River Valley and upper Midwest will see the greatest declines in Veteran population; it may be possible to consolidate the relatively proximal VA facilities in those regions as the population shrinks. At the same time, several regions are expected to see population gains. Most regions with gains, such as near Washington, D.C.; Charlotte, North Carolina; and San Antonio and Austin, Texas, are currently near VA facilities. Other growth areas, such as Montana, Wyoming, and Colorado, are not currently well covered. In these latter growth areas the population will remain relatively small, and access to telehealth and CBOC services may be important ways to meet Veteran needs. Similarly, rural areas in northwestern Washington State, northern Michigan, and northern Texas will remain areas with rural Veteran populations in 2024 that could also benefit from continued or expanded services.

Second, while the total Veteran population will be growing older on average through 2024, and health services related to aging will be needed everywhere, Veterans under age 35 will be concentrating in areas surrounding Los Angeles, Dallas, Washington, D.C., and northern New Jersey by 2024, and they will also constitute a greater proportion of the population in Northern

California, central Washington state, the Midwest, and Wyoming and Utah. In these areas it may be of particular importance to provide services relevant to younger Veterans compared to elsewhere. Much of the Southeastern seaboard, from Virginia Beach through the coast of Georgia will see a decrease in the proportion of the population that is under age 35 at the same time, and focus on services for younger Veterans may need to be shifted West and North.

Overall, the Veteran population in the Southwest has the most uneven alignment and most risk of future geographic misalignment by 2024. The Southwest has seen, and will continue to see, relatively strong population growth (Veteran and non-Veteran civilian alike). Because VAMCs in the Southwest are far more widely spaced apart, population centers in the Southwest are less likely to fall within a short distance of an existing facility, and less likely to have an alternative VAMC in proximity. Combined with the relatively younger Veteran population anticipated in this region relative to others by 2024, particular awareness of potential future service demand by this population is important for planning. Detailed analysis of access to specific types of services and VA facilities is presented in Assessment B, Section 4.

4   Enrollment in and Reliance on the VA Health Care System

4.1 Introduction

Understanding the volume and mix of VA health care services that Veterans will use in the future is critical for VA's resource and capability planning. The main challenge in measuring and describing Veterans' use of health care services is that many Veterans obtain some or all of their health care from non-VA sources, as described in Section 2. Understanding the future volume of VA health care services requires calculating (1) the number of Veterans enrolled in the VA health care system; (2) the number of Veterans who seek health care at a VA facility; and (3) Veterans' reliance on the VA health care system (i.e., the share of health care services that VA patients receive from VA versus from other sources).

The conceptual model of VA health care use, discussed in Section 2, highlights Veteran characteristics and VA policy as the main determinants of enrollment in and use of the VA health care system. Veteran characteristics that affect enrollment and use include the Veteran's sociodemographic characteristics, health care needs (including service-connected disabilities), and access to other health insurance. The "Combat Veteran" Authority of 2008, which extended enhanced eligibility and expedited enrollment for VA health care for Veterans of Afghanistan and Iraq, is an important policy affecting current patterns of enrollment and use among Veterans. This policy allows Veterans who served in a theater of combat operations after November 11, 1998, to enroll in VA without first establishing their priority group for a period of five years post-discharge. These Veterans are placed in priority group 6 unless they qualify for a higher priority group and, at the end of the five-year period, may be shifted to priority group 7 or 8.

Once Veterans enroll and are deemed eligible to receive care, they must make a choice about whether to use VA health care and how much care to consume. The majority of enrolled Veterans have access to other health care coverage, and approximately half of enrolled Veterans are also enrolled in Medicare or Medicaid (Congressional Budget Office, 2009; Goldberg, 2015). Enrolled Veterans receive the majority of their health care outside of VA (Goldberg, 2015). Based on EHCPM, VA estimates that current VA patients have on average about 21 percent of their total physical medicine (that is, physical therapy and occupational therapy) visits with VA, 38 percent of their emergency room visits with VA, and 66 percent of their prescriptions from VA.

In this section, we project future enrollment in the VA health care system and the future size of the VA patient population. We include the factors outlined in the conceptual model to the extent possible given the available data. These projections are used in Section 5 to project the future health care needs of the VA patient population. The primary task for Assessment A was to describe the current and projected demographics and unique health care *needs* of Veterans rather than current and future VA health care *use*. There are significant practical data and analytic challenges in measuring and projecting the health care services that Veterans demand or use. Nonetheless, we measure reliance for a select set of health care service categories in MEPS data and compare these reliance estimates with those used in EHCPM. We also introduce

a new reliance concept—population reliance—to convey the share of health care services that all Veterans (rather than only VA patients) receive from VA.

4.2 Analytic Approach

Overview of Methods and Data for Enrollment and Reliance Analysis

- We estimated the **probability of a Veteran enrolling** in the VA health care system taking into account age, sex, deployment status, service era, and a time trend using aggregated data from multiple sources.
- We estimated **the number of VA patients** from 2014 through 2024 by multiplying the number of enrollees by the probability of use among enrollees, which was calculated using the SoE.
- We estimated **VA patients' reliance on VA health care** using MEPS data from the household survey, the Prescribed Medicines file, the Office-Based Medical Provider Visits file, and the Inpatient Stays file.
- To compare our reliance estimates with VA's, we evaluated **reliance factors used by VA** by combining three separate EHCPM files.

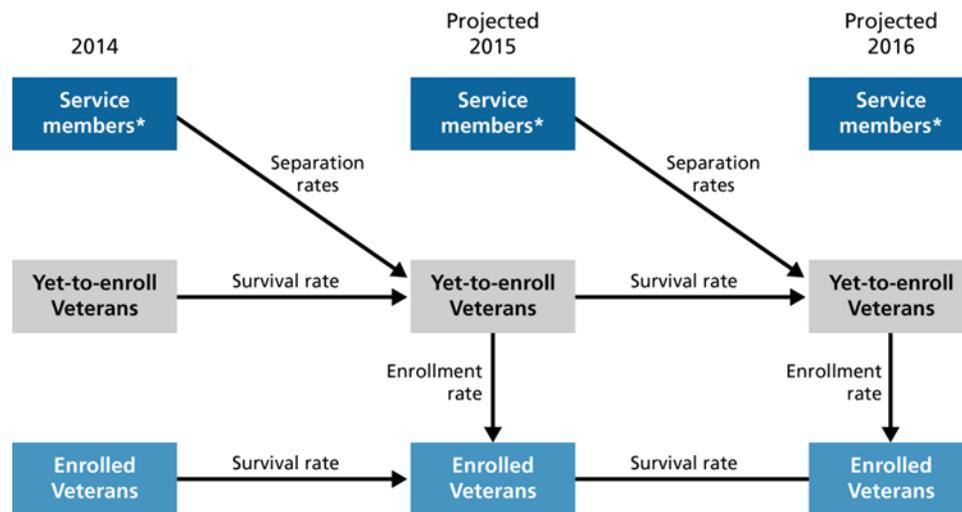
4.2.1 Projecting the Number of Veterans Enrolled in the VA Health Care System

As described in the conceptual model of VA health care use in Section 2, the decision to use VA for health care services is dependent on a number of factors, including VA policies, Veteran characteristics, cost, access, and perceptions of the care available through VA's health care system. The first step in the process of receiving VA health care services is enrollment in the VA health care system. Just as with the decision to seek care, the decision to enroll is a complex process influenced by many of the same factors. Ideally, we would have modeled an individual Veteran's decision to enroll in the VA health care system based on the factors included in the conceptual model, but we did not have access to a single data source linking all of these factors. We instead used data aggregated by age, sex, and deployment status (with respect to Afghanistan and Iraq) to model enrollment rates.

We estimated the probability of new enrollment in the VA health care system (given that a Veteran has yet to enroll) using a logistic regression model that incorporated age, sex, deployment status, service era (e.g., Vietnam War era), and a time trend.[27] Starting with 2015, predicted enrollment probabilities based on this model were applied to the population of yet-to-enroll Veterans to estimate the number of new enrollees. These new enrollees were added to the previous year's surviving population of enrolled Veterans. This process was repeated for each subsequent year. In Figure 4-1, we present a conceptual model of enrollment in the VA health care system that depicts this process.

---

[27] We estimated and projected VA enrollment using RAND Veteran population projections, DoD data, and VA administrative data. These data sources do not uniformly include information on income (or priority group), so we could not include income as a predictor of enrollment.

Figure 4-1. Conceptual Model of Enrollment in the VA Health Care System


NOTES: Survival rate is the probability that an individual survives to the next year

* Number of separations among service members are projected in Section 3.

We considered three different sets of assumptions about the probability of new enrollment in future years and compared the projected number of enrollees under each of these assumptions. First, we assumed that the probability of enrollment will continue to follow the recent pattern of enrollment, which we refer to as the *status quo* assumption. Second, we assumed that the probability of enrollment among Veterans who were deployed to Afghanistan and Iraq will follow the recent pattern of enrollment among Veterans who never deployed to Afghanistan or Iraq, which we refer to as the *never deployed* assumption. Third, we assumed that the probability of enrollment among Veterans who deployed to Afghanistan and Iraq will decrease over time by allowing the effect of deployment on future enrollment to decrease by 5 percent each year, which we refer to as the *decreasing enrollment* assumption. The never deployed and decreasing enrollment assumptions reflect the fact that we do not anticipate enrollment to remain at the current historical levels as we move away from the operations in Afghanistan and Iraq. There are several reasons why we postulate that this may occur: (1) the number of separating service members with deployment experience will decrease over time; (2) the number of all deployed Veterans within the five-year window of enhanced enrollment eligibility will decrease over time; (3) the percentage of separating service members with more than 19 years of experience (i.e., retiring and eligible for TRICARE) and with deployment experience will increase over time; and (4) the health status of separating service members who were deployed will improve because military personnel with more-serious deployment-related medical conditions are likely to leave earlier than those without such conditions. Each of these factors, among others, is expected to decrease enrollment rates among future Veterans who deployed. Further discussion is provided in Section 4.5.

Our projections of enrollment in the VA health care system do not account for the effects of the Great Recession. We used VA administrative data from 2008 to 2014 to model new enrollment, which does not provide us with sufficient data before the recession to properly account for its

impact on enrollment. Assuming that the Great Recession increased the probability of enrollment in the VA health care system, our projected enrollee counts are too high.

4.2.2 Projecting the Number of VA Patients

We projected the number of VA patients from 2014 to 2024 by multiplying the number of enrollees by the probability of use among enrollees. These VA patient projections account for mortality because they are based on the VA enrollee projections, which account for mortality as described in Section 4.2.1.

We estimated the probability of VA use among enrollees using the SoE from 2010–2014. We fit a logistic regression model for the probability of VA use that included age, sex, service era, Iraq-Afghanistan deployment status, and a linear time trend.[28] These characteristics were chosen to model VA use among enrollees because they aligned with the characteristics that were used to project enrollment. We present the predicted probabilities of using VA health care services using the estimated model in Appendix B, Table B-1. We also present the results of an extended model in Table B-2.

Ideally, we would have modeled an individual Veteran's decision to use VA health care services based on the factors included in the conceptual model, but using factors that were not included in our enrollment projections would have required additional modeling. For example, a Veteran's income is related to VA use; if we wanted to include income in our projections of VA use, it would have been necessary to project Veterans' future income. There are significant practical data and analytic challenges in projecting the future income of Veterans, which is why we decided against this approach.

Veterans who served in a theater of combat operations after November 11, 1998, are eligible for an enhanced period of enrollment for five years post-discharge. We checked the sensitivity of our results by including an indicator that a Veteran who deployed is within five years of separation in our VA use model; however, this indicator was not associated with use.

4.2.3 MEPS Analyses of Reliance

We calculated reliance using the 2008 to 2012 MEPS data, specifically data from the household survey, from the Prescribed Medicines file listing all prescriptions filled by MEPS respondents, the Office-Based Medical Provider Visits file, and the Inpatient Stays file. Prescribed medicine, office visit, and inpatient stay data from MEPS are based on self-reported utilization by survey respondents. MEPS staff audit a sample of prescriptions and visits. Our general approach followed four steps:

1. Identify Veterans and VA patients in the MEPS household files.

---

[28] We projected the number of VA patients from 2015–2024 by multiplying the number of projected enrollees by the probability of VA use among enrollees. Enrollees are not projected with income (or priority group) information, so we could not incorporate income-specific probabilities of VA use into the projections.

2. Identify in the MEPS data the prescribed medicines, office-based visits, and inpatient stays that were provided or paid for by VA.

3. Aggregate the number of services received by VA patients overall and those that were provided by or paid for by VA for each health care service category (e.g., physical and occupational therapy).

4. Calculate reliance by dividing the sum of services provided by or paid for by VA by the total number of services received.

We also calculated a *population reliance* factor (described below) for all Veterans in addition to our measure that is restricted to VA patients only. Further, we report reliance for multiple health care service categories: prescribed medicines, all office visits, specific office visit categories (evaluation and management, laboratory tests, radiology, kidney dialysis, and physical and occupational therapy), and inpatient stays involving surgical procedures. This selection of health care service categories is meant to give a sense of the variation in reliance across broad categories of health care services. Our selections were driven by the feasibility of roughly aligning health care service categories in MEPS with service categories in EHCPM; however, we do not imply that the MEPS and EHCPM health care service categories are identical. We also recognize that the unit of measurement in MEPS and EHCPM are not always consistent—for example, EHCPM counts prescriptions normalized to a 30-day supply, whereas we simply count prescription drug fills in MEPS.

For this analysis, we identified VA patients in MEPS by inferring whether an individual in MEPS is a VA patient based on the respondents' source of payment for health care. Specifically, we defined active VA patients as those respondents who had any payment by VA for services used. Unfortunately, MEPS data do not enable us to identify all Veterans who are eligible for VA services; we can identify only those eligible Veterans who use VA services. We defined health care service categories and identified services that were provided by or paid for by VA, as described in Table 4-1. The remaining services in each category were assumed to be provided and paid for by some other source. For each category and population, we defined reliance as the ratio of the sum of services provided by or paid for by VA to the sum of total services received by the population, weighted appropriately.

Our reliance measures can be interpreted as the proportion of care in a service category that VA patients receive from VA. We calculate a second reliance measure, a *population reliance* estimate, that is identical to the formula above but calculates reliance for all Veterans, including Veterans who are not VA patients. The interpretation of population reliance is the proportion of care in a service category that all Veterans (rather than VA patients) receive from VA. We focused on utilization—measured in events—rather than spending, in part for consistency with the VA definition of reliance and in part to control for differences in health care costs or prices across payers and systems.

Table 4-1. Data Sources and Category Definitions

Service Category	Data Source	Criteria
Prescription drugs	MEPS Prescribed Medicines files, 2008–2012	All prescription events with VA paid amount > $0. We did not adjust MEPS prescribed medicine events to account for differences in days supplied across events. While this might be feasible for some MEPS events (e.g., events with 90 days supplied), a significant share of MEPS events have an "unknown" number of days supplied.
Office visits	MEPS Office-Based Medical Provider Visits files, 2008–2012	All office visits with place of service = "VA facility" OR VA paid amount > $0
Office-based evaluation and management visits	MEPS Office-Based Medical Provider Visits files, 2008–2012	All office visits with visit type = "General checkup" or "Follow-up or post-operative visit" AND (place of service = "VA facility" OR VA paid amount > $0)
Office-based laboratory services	MEPS Office-Based Medical Provider Visits files, 2008–2012	All office visits with "this visit patient had lab tests" = 1 AND (place of service = "VA facility" OR VA paid amount > $0)
Office-based dialysis services	MEPS Office-Based Medical Provider Visits files, 2008–2012	All office visits with "this visit patient had dialysis" = 1 AND (place of service = "VA facility" OR VA paid amount > $0)
Office-based radiology services	MEPS Office-Based Medical Provider Visits files, 2008–2012	All office visits with "this visit patient had…" one of the following = 1: sonogram, x-rays, mammography, or MRI, AND (place of service = "VA facility" OR VA paid amount > $0)
Office-based physical/occupational therapy services	MEPS Office-Based Medical Provider Visits files, 2008–2012	All office visits with ("this visit patient had physical therapy" = 1 OR "this visit patient had occupational therapy") AND (place of service = "VA facility" OR VA paid amount > $0)
Inpatient stays involving surgical procedures	MEPS Hospital Inpatient Stays files, 2008–2012	All inpatient stays with imputed VA facility or provider payments > $0 and an indicator for "any operation or surgery performed while the respondent was in the hospital"

4.2.4 EHCPM Analyses of Reliance

While we did not have access to the underlying data used to replicate the EHCPM reliance calculations from the ground up, we were able to evaluate reliance factors provided by VA. We combined three separate EHCPM files to adjust VA-provided reliance factors so that they are more analogous to those that we calculated in MEPS. These files contained the following:

- Reliance estimates for 25 health care service categories by priority group, age category, whether or not the Veteran enrolled prior to eligibility reform, sex, and submarket (subdivisions of Veterans Integrated Service Networks)
- Utilization, measured in units relevant to individual health care service categories and defined using the same criteria as the reliance factors

- Counts of unique Veterans who used at least some services in each health care service category.

Because different VA-provided EHCPM output files were formatted differently, we applied a set of adjustments so that the different input files used the same age categories and priority groups.

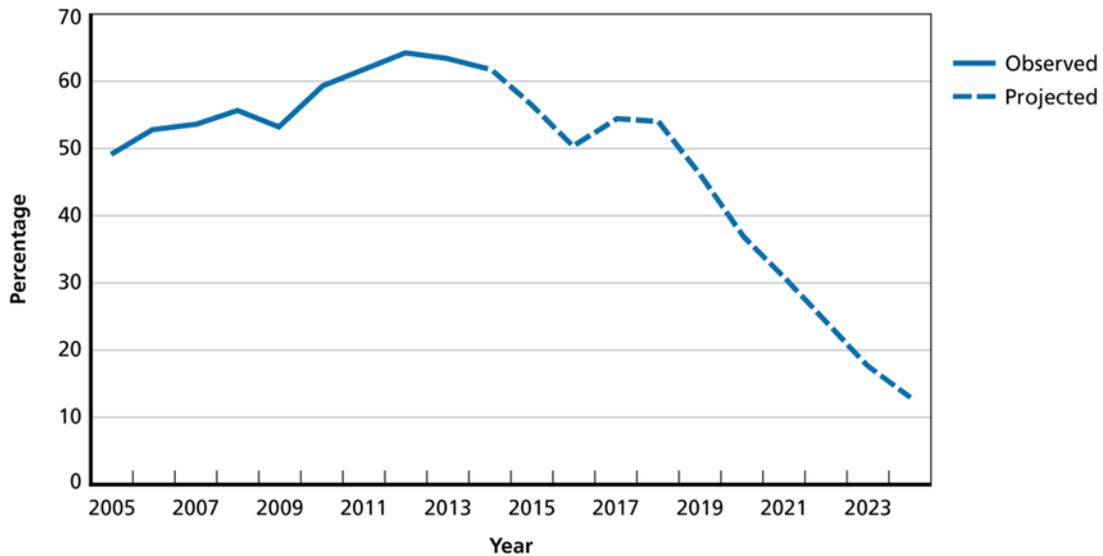
4.3 Results

4.3.1 Projection of Veterans Enrolled in the VA Health Care System

Currently, the most important driver of enrollment in the VA health care system is the flow of separating Veterans who were deployed in Afghanistan and Iraq. This is occurring, in part, because of the enhanced period of eligibility for deployed service members and an increased need for health care due to combat experience. As of the end of FY 2014, 67 percent of eligible Afghanistan and Iraq Veterans were enrolled in the VA health care system, and 60 percent of these eligible Veterans had obtained VA health care (Epidemiology Program Office of Public Health, 2015). Both of these indicate that current enrollment rates among Veterans who were deployed in Afghanistan and Iraq are high.

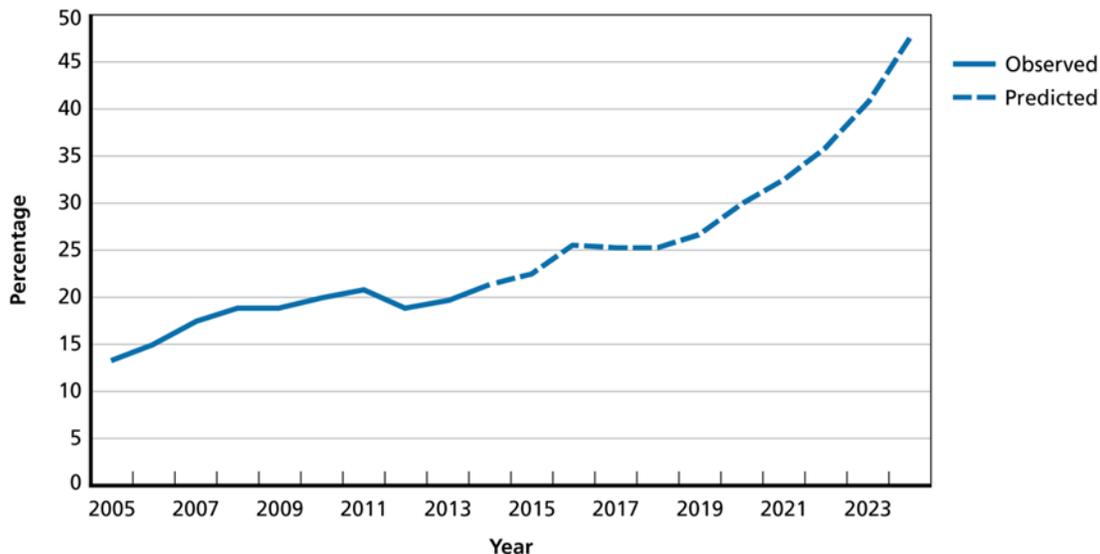
We estimate that the percentage of all Veterans who deployed to Afghanistan or Iraq will increase from 9.1 percent in 2014 to 15.1 percent in 2024, corresponding to an increase of approximately 700,000 Veterans. Veterans who served in Afghanistan or Iraq will make up an increasing share of the total Veteran population and, as already stated, are much more likely to enroll in the VA health care system. Understanding the future pattern of enrollment among these 700,000 yet-to-separate Veterans who deployed is the first step in understanding the volume and mix of VA health care services that Veterans will use in the future. Assuming that all of these yet-to-separate Veterans join the VA patient population would increase the population by more than 10 percent.

As we move away from these combat operations, fewer separating Veterans will have deployment experience, and the overall new enrollment rates in the VA health care system will likely decrease. Figure 4-2 illustrates that the percentage of separating service members who were deployed is estimated to decrease from 61.7 percent in 2014 to 12.8 percent in 2024.

Figure 4-2. Percentage of Separating Veterans Who Were Deployed


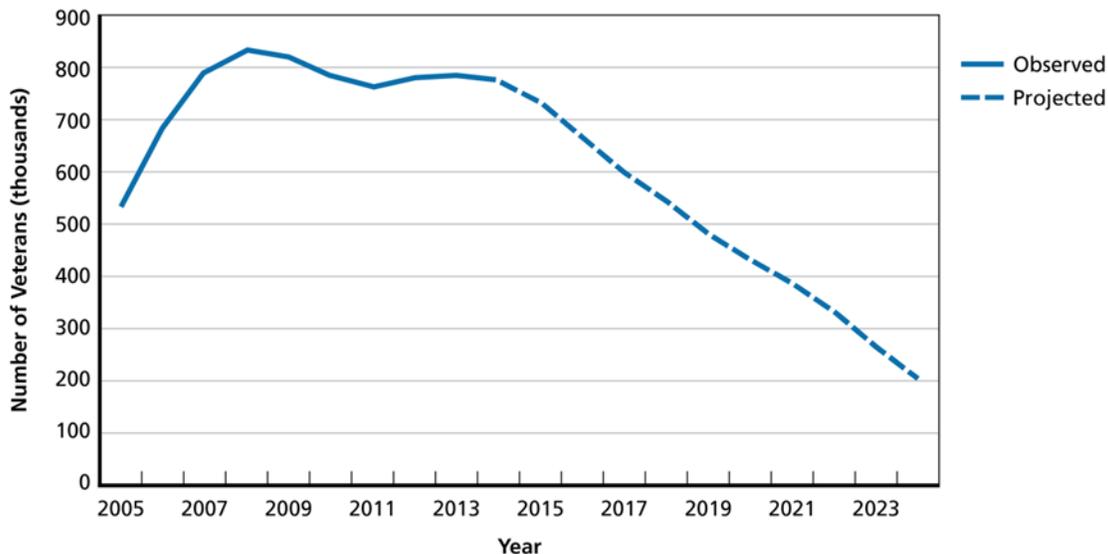
SOURCE: RAND analysis of DoD data.

In addition, the characteristics of separating Veterans with deployment experience will change as we get further away from the operations in Afghanistan and Iraq. We describe three specific examples. First, separating Veterans will become older and more experienced between 2015–2024. These Veterans are more likely to be retiring from the military and are eligible for TRICARE. 85 percent of military retirees under age 65 have no private health coverage and are reliant on TRICARE (Office of the Assistant Secretary of Defense (Health Affairs), 2015). In 2010, 23 percent of Veterans with TRICARE-only coverage used some VA health care; an unknown amount of this care was provided through a DoD-VA sharing agreement. Figure 4-3 illustrates that by 2024, nearly 50 percent of separating Veterans who were deployed are separating with at least 19 years of experience and are likely to have TRICARE, compared with less than 25 percent in 2014. Although the flow of separating Veterans eligible for enhanced enrollment will continue, they will be fewer in number, less dependent on VA health care services due to eligibility for TRICARE, and less likely to enroll in the VA health care system.

Figure 4-3. Percentage of Separating Veterans with 19+ Years of Service Among Those Who Were Deployed


SOURCE: RAND analysis of DoD data

Second, fewer Veterans will be within the five-year window of enhanced enrollment eligibility. Figure 4-4 illustrates a steep decline in the projected number of Veterans who were deployed and are within five years of separation. It is expected that enrollment rates will decline as a result.

Figure 4-4. Number of Veterans Within 5 Years of Separation Among Those Who Were Deployed


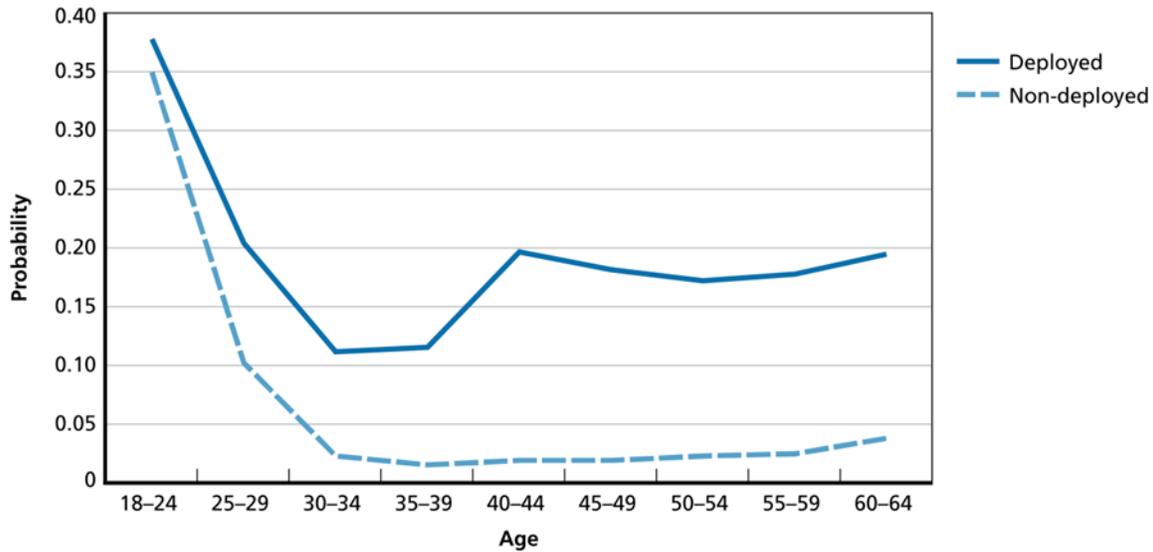
SOURCE: RAND analysis of DoD data.

Third, we expect the health status of separating Veterans to improve over time. Veterans with service-connected health care needs as a result of deployment are likely to separate earlier if they do not meet medical retention standards, and once separated, are more likely to seek care

for the service-connected health need that contributed to their separation. In addition, selection of service members to continue in military service may be based on their overall health due to the military health and fitness standards. We expect that as the number of active duty service members who were deployed decreases, the overall health status of these service members will improve. If true, the overall health status of future separating Veterans who were deployed will improve over time. As indicated in the conceptual model in Section 2, a Veteran's need of health care is associated with his or her decision to seek care. If separating Veterans' health statuses are improving over time, we expect lower enrollment rates as a result.

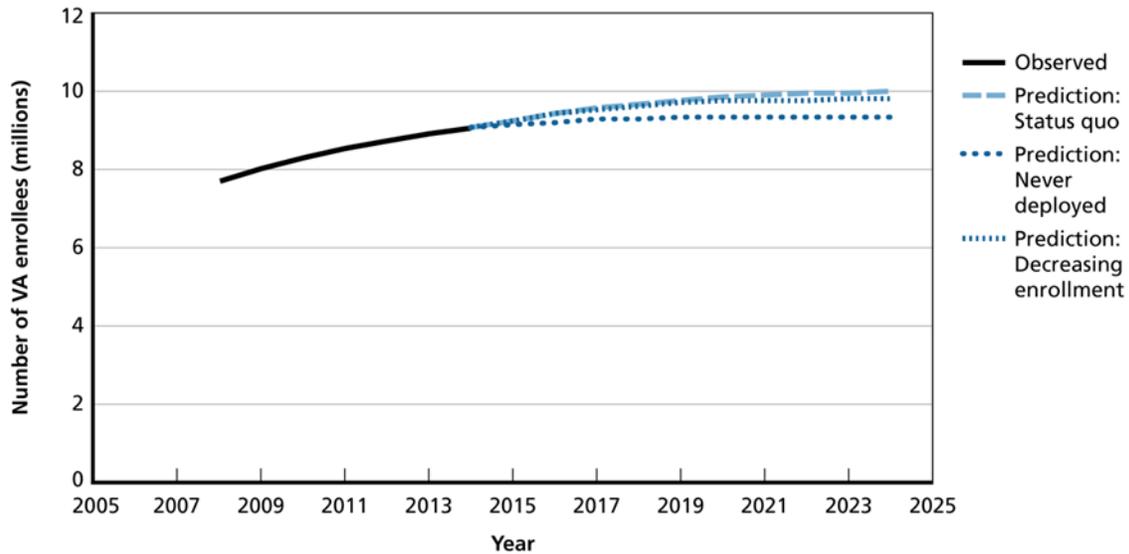
We did not have access to data that would allow us to incorporate this type of information into our projections. Therefore, we took a sensitivity analysis approach when projecting the number of enrollees. Our three sets of assumptions provide us with a range of plausible projections and inform us on the sensitivity of our final results to these assumptions. Recall that our status quo assumption is that the recent pattern of enrollment will continue in the future. While a reasonable baseline, we expect this assumption to overestimate the number of enrolled Veterans moving forward due to the previously stated reasons. The never deployed assumption attempts to account for the expected decline in enrollment among Veterans who were deployed by aligning their pattern of enrollment with Veterans who were never deployed. This can be considered as a lower bound, as the probability of new enrollment among yet-to-enroll Veterans is much lower among Veteran who were never deployed (in 2014, 2.7 percent versus 18.3 percent). The decreasing enrollment assumption is a trade-off between the first and second. We assume that the effect of deployment on enrollment rates will decrease by 5 percent each year and reflects the previously described changes in the characteristics of separating Veterans over time.

Note that these assumptions focus on the enrollment rates of Veterans who were deployed. This is because the probability of enrollment among Veterans who never deployed is much lower than their deployed counterparts, as demonstrated in Figure 4-5. In addition, the probability of new enrollment appears to be much more consistent for non-deployed Veterans among those age 30 and older.

Figure 4-5. Probability of New Enrollment, by Age (2009–2014)


SOURCE: RAND analysis of VA, DoD, and Census data.

Figure 4-6 illustrates the historical trend and projected number of VA enrollees under our three sets of assumptions. We project the number of VA enrollees to increase under all three of our projection assumptions, but by varying degrees. The number of VA enrollees in 2014 was 9.1 million Veterans, and our projections predict increases to 10.0 million, 9.8 million, and 9.3 million in 2024. All three sets of assumptions show an increase in the projected number of enrollees for several years, but these increases are projected to level off or reverse around 2020. This occurs as enrollment rates among younger Veterans are unable to offset the mortality rates of older Veterans and as most Veterans who were deployed in Afghanistan or Iraq have already made their initial decision on enrollment.

Figure 4-6. VA Enrollee Trends and Projections (2008–2024)


SOURCE: RAND analysis of VA, DoD, and Census data.

The difference between the projection under the status quo assumption and the never deployed assumption is about 670,000 enrollees by 2024, amounting to about 7 percent of the current enrollee population. This difference is driven by the pattern of enrollment among Veterans who deployed in Afghanistan and Iraq and serves as a range of plausible projections. That is, we expect the actual pattern of enrollment to fall in between these two projections. The difference between the projected enrollee population under the status quo assumption and the decreasing enrollment assumption is even smaller, approximately 200,000 enrollees by 2024.

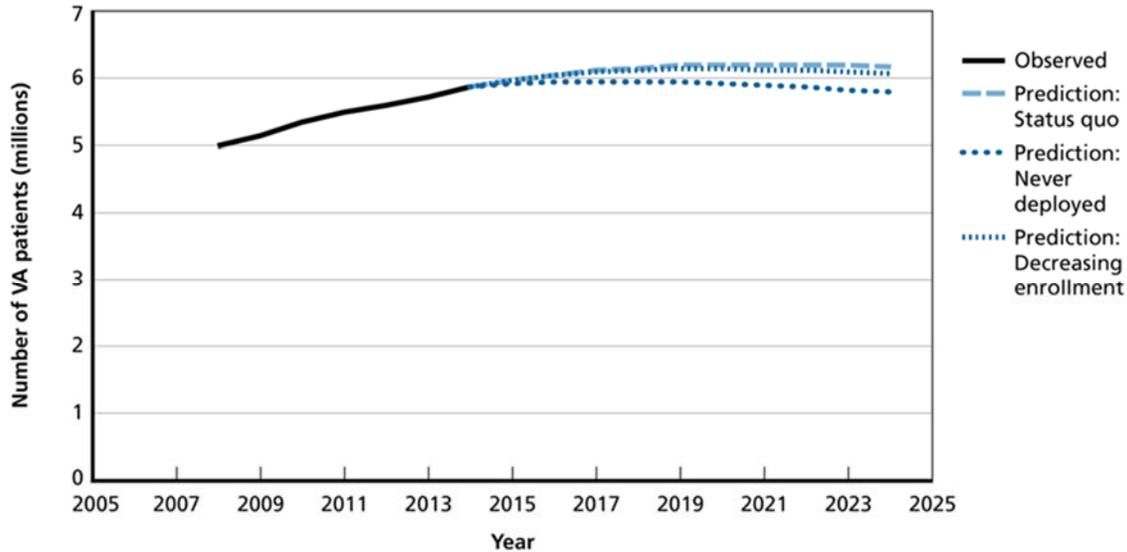
Enrollment in the VA health care system is only the first step toward understanding the volume of VA health care services that Veterans will use in the future.

4.3.2 Projection of VA Patients

We projected the number of VA patients by multiplying the number of enrollees by the probability of use among enrollees. While we estimate only one model for the probability of VA use conditional on enrollment, we apply these estimates to the enrollee projections under each of the three sets of assumptions to produce three sets of projections for the number of VA patients. The differences in the projected number of VA patients are caused by differences in the total number of projected enrollees and the demographic composition of projected enrollees. The probability of using VA health care services conditional on enrollment, age, sex, service era, deployment status, and year does not differ.

Figure 4-7 illustrates the historical trend in the number of VA patients and our projections. We project little change in the total number of VA patients. The number of VA patients in 2014 was 5.9 million, and we project the number of VA patients will be between 5.8 million and 6.2 million in 2024. The pattern in the observed and projected number of VA patients roughly

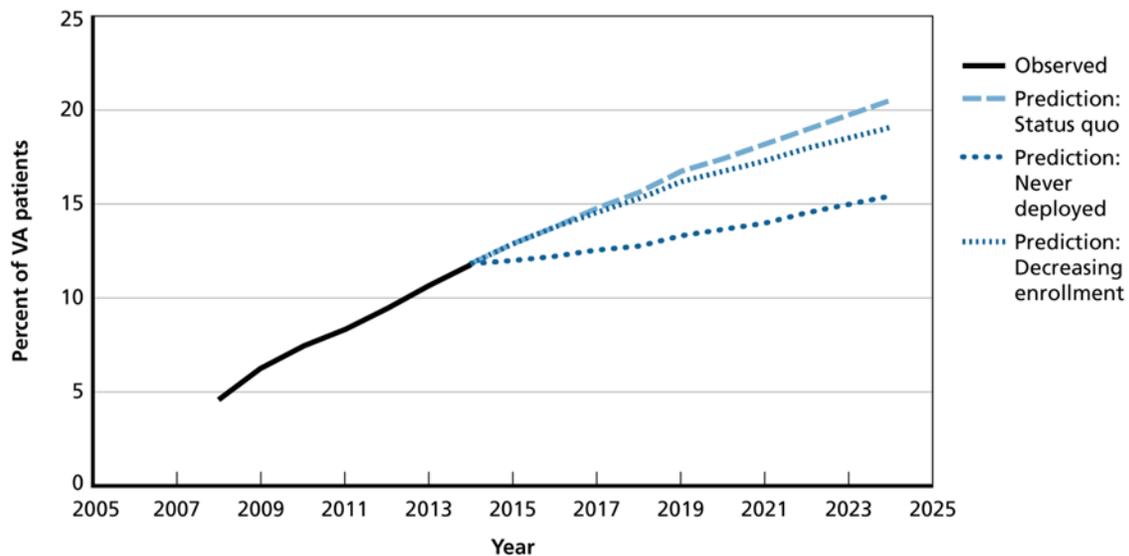
follows the pattern in enrollment. While the number of VA patients increased nearly 20 percent between 2008–2014, we project that this trend will flatten out and reverse over the next 10 years. This predicted trend is largely driven by the trend in the number of VA enrollees.

Figure 4-7. VA Patient Trends and Projections (2008–2024)


SOURCE: RAND analysis of VA, DoD, and Census data.

The difference between the projected number of VA patients under the status quo assumption and under the never deployed assumption is about 370,000 patients by 2024, amounting to 6.5 percent of the current VA patient population. The difference between the projected enrollee population under the status quo assumption and the decreasing enrollment assumption is even smaller, only 110,000 patients by 2024.

The percentage of VA patients who served in Afghanistan is projected to increase over the next decade, as illustrated in Figure 4-8**.** By 2024, 19 percent of VA patients are projected to have served in Afghanistan and Iraq. The long-term health effects of service in Afghanistan and Iraq are unknown, and it is imperative that VA monitor trends in health care utilization among these Veterans to ensure adequate resources and capabilities to meet their unique and changing health care demands.

Figure 4-8. Percentage of VA Patients Who Served in Afghanistan and Iraq (2008–2024)


SOURCE: RAND analysis of VA, DoD, and Census data.

We explored whether or not the period of enhanced eligibility was related to VA use among enrollees. Veterans who enrolled in priority group 6 during the period of enhanced eligibility are most likely to be shifted to priority group 7 or 8 at the end of the enhanced eligibility period. Among VA enrollees who were deployed in Afghanistan and Iraq, there is no difference in the percentage of Veterans using VA health care services between priority group 6 enrollees within the period of enhanced eligibility (35 percent) and priority group 7 or 8 enrollees outside the period of enhanced eligibility (37 percent). This indicates that the probability of VA use is not different between enrollees within and outside the period of enhanced eligibility, but it does not provide any information on how reliance may change when the period of enhanced eligibility ends. Veterans who move to a lower priority group will have co-pays, but these are modest; otherwise, there is little to no change in access to care or service availability. One explanation of the continued use of VA health care is that the enhanced eligibility policy gets Veterans to enroll in the VA health care system who would have otherwise not enrolled. Once these Veterans enroll and begin receiving VA health care, they are satisfied with the quality of care that they are receiving and continue seeking VA health care.

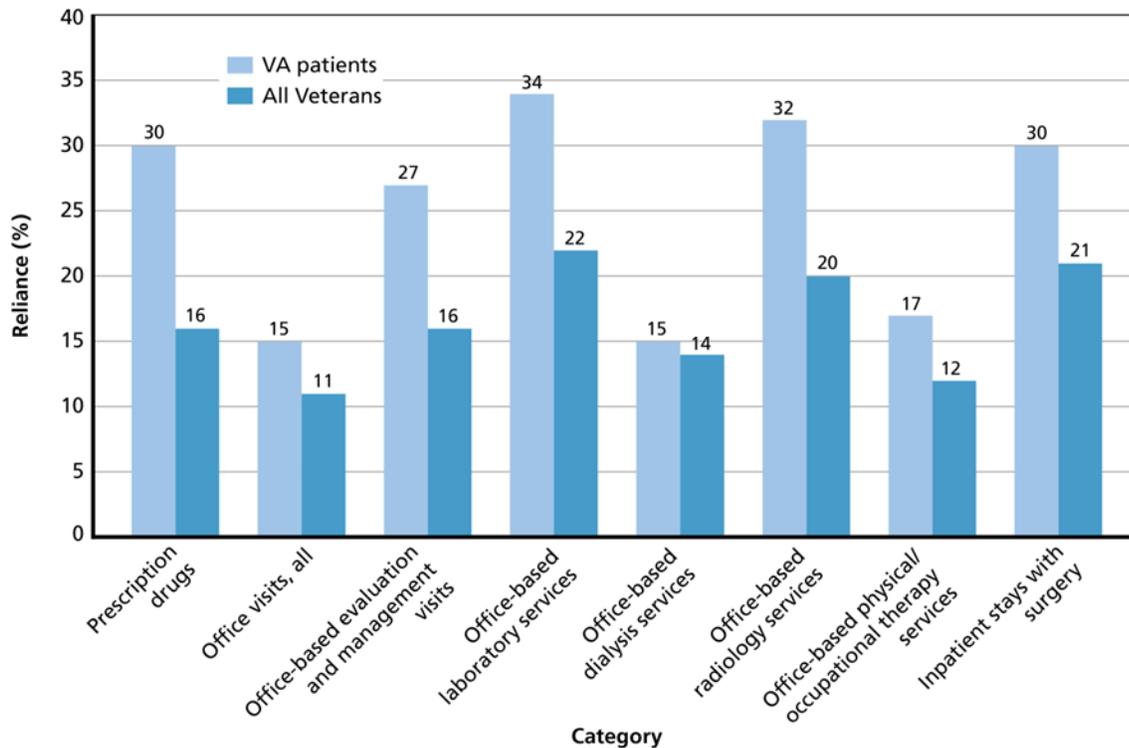
In addition to the factors and trends that affect the health care needs of the Veteran population overall, the health care needs in the VA patient population are determined in part by who uses VA health care services. Changes in VA policies—such as new priority group cutoffs for enrollment eligibility, additions of new presumptive service-connected conditions, or changes to the enhanced eligibility benefits for new combat Veterans—will directly affect the number and composition of Veterans who are eligible to receive VA health care services. External factors that affect access to affordable health care, such as fluctuations in the economic climate or changes in the eligibility rules for other public health programs (e.g., Medicare) have the potential to affect VA use rates and the composition of the VA patient population. We assumed that these factors remain constant over the next 10 years in these baseline projections. The

effects of policy changes on future Veteran, enrollee, and patient counts are considered in the scenario analyses in Section 6.

4.4 Reliance Analysis Results from MEPS Data

4.4.1 Overall Veteran and VA Patient Reliance on VA

Reliance on VA varies across the select health care service categories that we examined using MEPS data, ranging from 15 percent for all office-based visits to 34 percent for office-based laboratory services (see Figure 4-9). Because many Veterans do not use care provided or paid for by VA, there are also important differences between reliance calculated only for VA patients and population reliance calculated across all Veterans. Adding non-patient Veterans to the reliance calculation increases the reliance denominator but not the reliance numerator. As a result, each population reliance estimate is lower than the corresponding VA patient-only reliance factor. For example, while VA patients obtain 30 percent of prescription fills from VA (according to MEPS), across all Veterans, the prescription drug reliance rate falls to 16 percent. Both reliance factors may be relevant to policymakers depending on the context.

Figure 4-9. Reliance for VA Patients and All Veterans, by Service Category


SOURCE: RAND analysis of 2008–2012 MEPS data.

4.4.2 Veteran and VA Patient Reliance on VA by Age, Demographics, and Health Status

There are important differences in reliance across Veterans with different demographic, health status, and insurance coverage characteristics. Figures 4-10 through 4-15 report prescription drug, office visit, and inpatient surgery reliance rates for VA patients and all Veterans, both overall and across a range of Veteran subpopulations. Notably, reliance for all three health care service categories is significantly higher for younger age groups (who are less likely to have other health insurance) than for older Veterans who are likely to have access to other sources of coverage, such as employer-sponsored insurance or Medicare.

While reliance for office visits is similar across male and female Veterans, male Veterans have higher prescription drug reliance than female Veterans (35 percent versus 26 percent), and female Veterans have considerably higher inpatient surgery reliance than male Veterans. The inpatient surgery result—as well as several large swings in reliance across age groups, such as the change in inpatient stays with surgical procedures across the mid-30s to late-40s age categories—could reflect cohort effects, availability of other coverage, changing health care needs, or small sample sizes. Lower-income Veterans have generally higher reliance rates across health care service categories. Finally, Veterans who self-report being in fair or poor health or who are uninsured have relatively high reliance rates compared with other Veterans.

Reliance rates for all Veterans (Figures 4-11, 4-13, and 4-15) are lower than reliance rates calculated just among VA patients (Figure 4-10, 4-12, and 4-14).

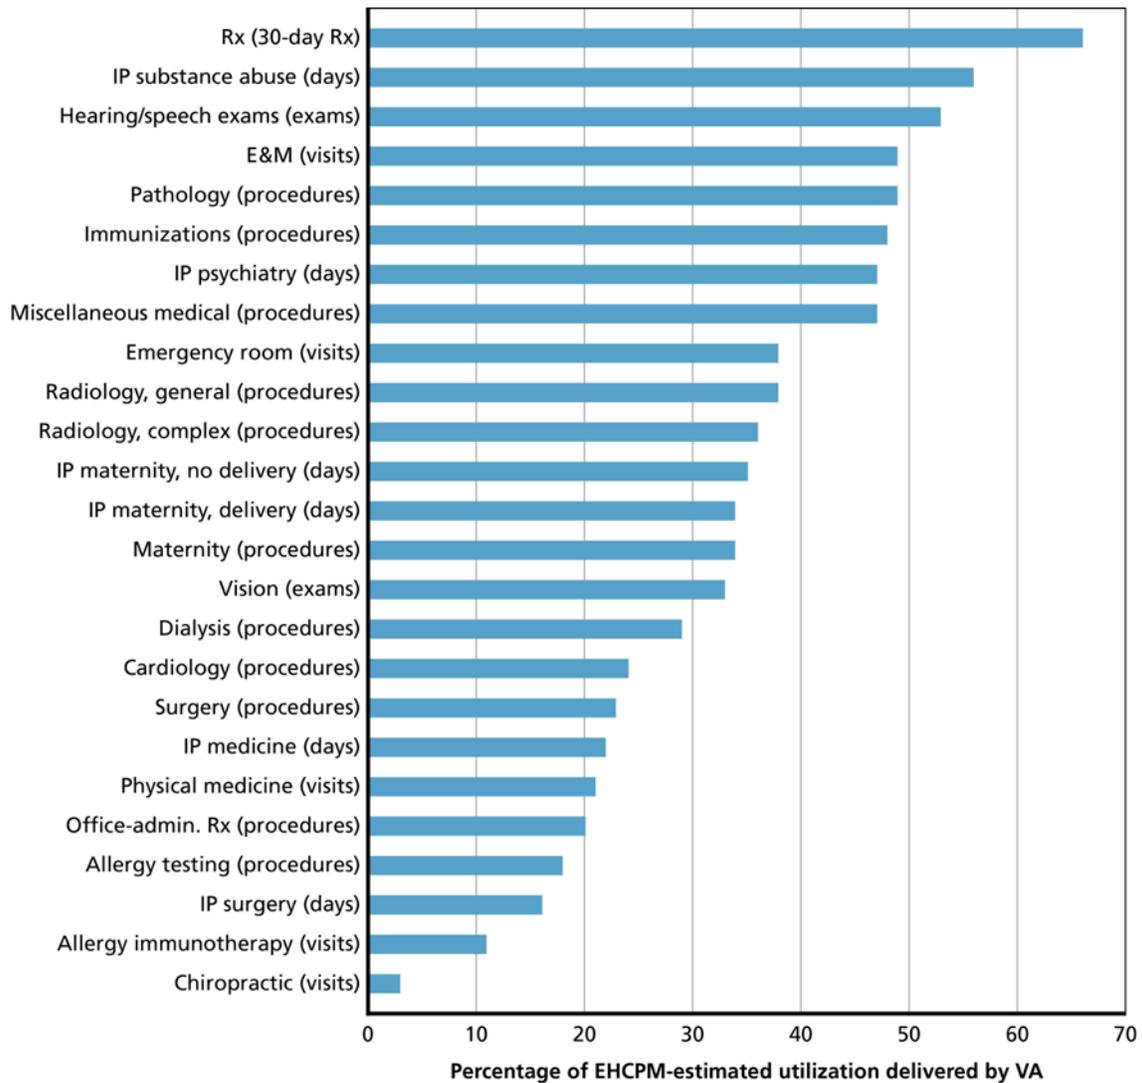
4.5 Reliance Analysis Results from EHCPM

This analysis, which draws on output from the ECHPM, addresses VA enrollees rather than patients. Figure 4-16 presents reliance rates among enrollees for each health care service category that is projected in EHCPM using information from the private sector rather than only information from VA. We omit other health care service categories that are projected based on VA historical utilization patterns, such as outpatient mental health, because EHCPM does not separately estimate reliance for these categories. Reliance ranges from a high of 66 percent for prescription drugs to a low of 3 percent for chiropractic service visits.

Figure 4-16. EHCPM-Reported Reliance, by Service Category


SOURCE: RAND analysis of EHCPM reliance factors and data.
NOTES: Rx = prescription; IP = inpatient; E&M = evaluation and management.

There is significant variation in reliance rates among different Veteran subpopulations. For example, reliance for prescription drugs and for outpatient evaluation and management visits (i.e., outpatient visits that do not involve any procedures) generally decreases across Veteran age categories, with a consistent "bump" in reliance for Veterans at age 45 through Medicare eligibility at age 65 (Figures 4-17 and 4-18).

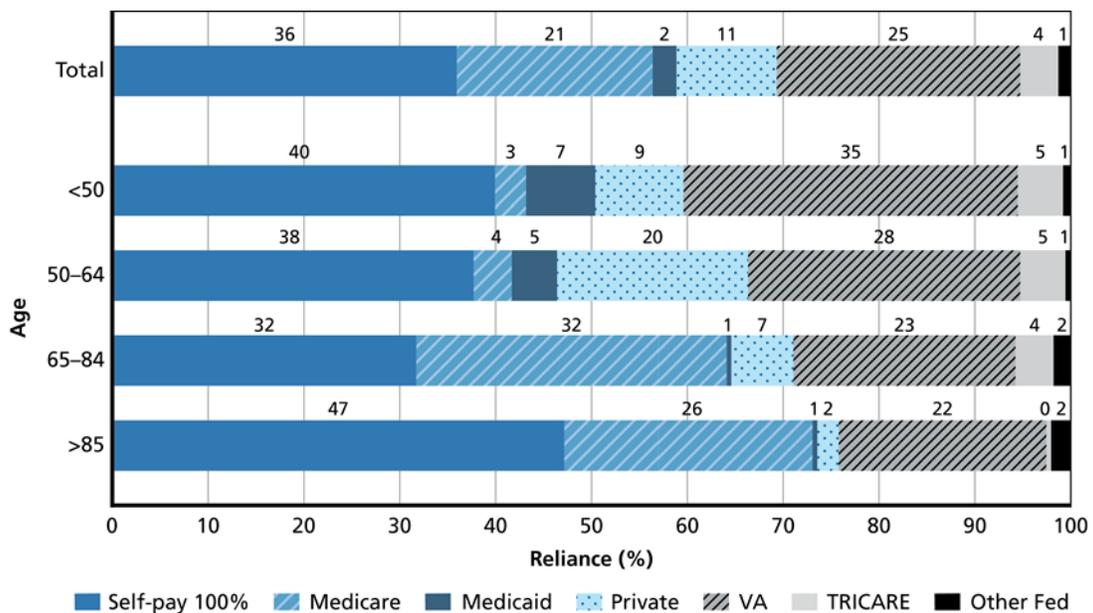
NOTE: E&M = evaluation and management.

4.6 Discussion of Reliance Analysis Results

When measured using external data from MEPS, reliance of VA patients on VA care tends to be lower than reliance calculated from EHCPM. For example, for prescription medications, reliance measured in MEPS is roughly 30 percent, compared with 66 percent in EHCPM—meaning that using the MEPS analysis, VA patients use VA services for a smaller proportion of their prescription medications. The differences are particularly stark given that the EHCPM focuses on enrollees, while the MEPS analysis focuses on VA patients. Because some enrollees do not use VA health care at all, one might expect that reliance rate would be higher among patients than enrollees. The one exception to this finding is inpatient stays with surgical procedures— where reliance measured with MEPS is nearly twice as high as that measured with EHCPM. This difference could be due in part to the different unit of measurement across these two data sources—days in EHCPM and stays in MEPS. A lower EHCPM reliance rate could be explained by shorter VA stays on average compared with the average length of stay across all of Veterans' surgical inpatient stays.

For prescribed medicines, whether or not drugs paid entirely out of pocket are included in the reliance denominator has a significant impact on the reliance estimate. In MEPS, prescriptions paid entirely out of pocket account for more than one-third of VA patient prescription drug events overall, and nearly half of prescription drug events for VA patients over age 85 (Figure 4-19). These prescriptions may be low-cost generic drugs (such as $5 generics offered at chain pharmacies and "big box" retailers). For the health care service categories that we analyzed in this section, reliance in EHCPM is calculated using inputs from Medicare for the over-65 population and from commercial benchmarks and the SoE for the under-65 population. Based on these data sources, it is not clear whether the significant share of cash transactions observed in MEPS is accounted for in VA's reliance estimates.

Figure 4-19. MEPS-Based Coverage for Prescription Drug Events, VA Patients


SOURCE: RAND analysis of 2008–2012 MEPS data.

MEPS-based reliance estimates across health care service categories suggest that lower-income Veterans, Veterans in rural areas, Veterans without other sources of coverage, and Veterans with poorer self-reported health status have higher reliance rates than other Veterans. That is, these groups obtain a larger proportion of their care from VA than other groups of Veterans.

The MEPS reliance estimates capture all health care utilization regardless of payer and regardless of whether the service is captured in VA encounter and claims data. However, there are important limitations when using MEPS to calculate reliance. First, MEPS contains relatively limited information on the specific health care services that patients receive. Second, the MEPS sample is small and for some health care service categories includes few Veterans, especially when restricting to specific Veteran subpopulations defined by age or other characteristics. Third, it is not always fully apparent in MEPS when services were (a) delivered by VA or (b) paid for by VA and delivered by private providers (i.e., purchased care). Fourth, MEPS estimates of health care utilization are based on respondents' recollections of the care they received, not on transactional data. Finally, some severely ill, high-utilization patients may drop out of MEPS when they die or experience an extended hospitalization. As a result, MEPS may omit utilization for the sickest patients.

Calculating reliance across the full range of health care service categories and for all Veteran subpopulations—as is done in EHCPM—is currently a considerable undertaking due to the lack of data sets describing the complete health care utilization of Veterans. Despite these limitations, MEPS provides comprehensive data that can be used to estimate reliance for Veterans directly rather than through analogy to non-Veteran populations. Future VA surveys or partnerships between VA and AHRQ (the organization that runs MEPS) could be designed to generate data for this purpose.

4.7 Summary of Key Findings

The number of Veterans receiving VA health care is projected to peak over the next 10 years. While the Veteran population is projected to decline by 20 percent over the next 10 years, the VA patient population is projected to reach its peak level in 2019. Use of VA has increased across all demographic groups since 2005, and the portion of Veterans under age 35 who are VA patients has increased threefold. The growth of VA use by Veterans may be related to outreach efforts on the part of VA, policies that have expanded the list of conditions granting presumptive eligibility for VA services, and streamlined enrollment processes. Continued increases in the rates of VA use are expected to slow the decline in the number of VA patients.

Understanding the future demand of health care services among Veterans who served in Iraq or Afghanistan is critical. By 2024, about 19 percent of VA patients are projected to have served in Afghanistan or Iraq. The long-term health impacts of service in Afghanistan and Iraq are unknown. It is imperative that VA monitor trends in health care utilization among these Veterans to ensure adequate resources and capabilities to meet the unique and changing health care demands of these Veterans

Veterans continue to seek VA health care after the period of enhanced eligibility closes. Among VA enrollees who were deployed in Afghanistan or Iraq, there is no difference in the percentage of Veterans using VA health care services between priority group 6 enrollees within the period of enhanced eligibility and priority group 7 or 8 enrollees outside the period of enhanced eligibility. This indicates that Veterans continue to use VA health care services after being shifted to a lower priority group at the end of the enhanced eligibility period. One plausible explanation for this pattern is that the enhanced eligibility policy encourages some Veterans who otherwise would not have used VA to seek care there. Then, if their needs are being met, or if employment or other circumstances do not present other health care options, they may continue to use VA beyond the enhanced eligibility period.

Health status and demographic factors influence reliance. Reliance estimates from MEPS, a nationally representative survey of the noninstitutionalized population, suggest that lower-income Veterans, Veterans in rural areas, Veterans without other sources of coverage, and Veterans with poorer self-reported health status have higher reliance rates than other Veterans.

Estimates from MEPS data show lower rates of reliance than those derived from VA's EHCPM model. For example, for prescription drugs, reliance measured in MEPS indicates that Veterans rely on VA to obtain roughly 30 percent of their prescription drugs compared with an estimate of 66 percent from EHCPM, although there are important differences between the two sources of reliance estimates.

The decision to include or exclude Veterans who are not VA patients influences reliance rates. Including Veterans who are not VA patients in reliance estimates yields lower "population reliance" rates. For example, reliance for prescription drugs among VA patients is 30 percent, while reliance for prescription drugs across all Veterans is 16 percent. Both statistics may be useful to decision-makers.

---

5 Health Care Needs of the Veteran Population

5.1 Introduction

Health care needs are an important determinant of demand for health care services. The aim of this section is to examine the health care needs of all Veterans, and of Veterans who use VA health care services in particular, so that VA can better anticipate and meet Veterans' needs.

Using the most recent data available, we first assessed the health care needs of all Veterans and of Veterans who have used VA health care services in the past year. We then projected the health care needs of both populations forward over a 10-year time horizon. We discuss the findings in three main sections:

An assessment of the unique health care needs of current Veterans relative to non-Veterans. As in earlier sections, we define the unique health care needs of Veterans as those that disproportionately affect Veterans relative to non-Veterans. These include both service-connected conditions, such as PTSD, and other conditions that are more prevalent among Veterans than non-Veterans, including diabetes and cancer. Veterans with such conditions may be better served by specialists located at VA facilities if the prevalence in the national population is low and if non-VA providers are less equipped to address these conditions. To identify the unique non-combat-related health care needs of Veterans, we compared the prevalence of key health conditions among the current Veteran population with those among the non-Veteran population.

An assessment both of the health care needs of VA patients relative to Veterans who are not VA patients and of factors related to VA use. Veterans who meet VA basic eligibility and minimum service duty requirements (U.S. Department of Veterans Affairs, 2015c) can apply to claim VA benefits. Veterans, therefore, must choose to apply, enroll if deemed eligible, and finally choose to use VA services (*take-up*) if enrolled. Although we cannot observe all of this information in the data sources we analyzed, we can differentiate between Veterans who use VA services (whom we define as *VA patients*) and those who do not in a given year. An understanding of why Veterans become VA patients is needed to predict how changes in VA policy and other factors external to VA will affect the size and composition of the patient population. We therefore compared the prevalence of health conditions among VA patients with Veterans who were non-VA patients and analyzed which Veteran characteristics (including the presence of particular health conditions) were associated with receiving care at VA facilities.

Projections of the future health care needs of Veterans and VA patients for the years 2015–2024. The population of Veterans and VA patients may change substantially in the next decade as the current population ages and as new Veterans with different demographic characteristics and military service experiences choose to use VA services. We projected the prevalence of the health conditions of Veterans and VA patients forward over the next 10 years, accounting for predicted changes in their demographic composition and their service experiences.

5.2 Overview of Methods

Overview of Methods and Data for Veteran Health Care Needs Analysis

- We compared the unadjusted prevalence of diagnosed health conditions among Veterans with the unadjusted prevalence of the same conditions among non-Veterans.
- We then compared the same prevalence rates adjusted for demographic characteristics, including age, sex, and race/ethnicity.
- Similarly, we compared the unadjusted and adjusted prevalence of diagnosed health conditions among VA patients with the prevalence of the same conditions among Veterans who do not use VA health care services.
- We projected the prevalence of diagnosed health conditions among Veterans and VA patients by applying our prevalence estimates to the projected Veteran population (Section 3) and the projected VA patient population (Section 4).
- Data for this analysis came from MEPS, supplemented with encounter data from VA and MHS.

5.2.1 Data Sources

Our analyses relied on several data sources, including Veteran and nationally representative survey data. We highlight some of the primary sources of health data here. Further details about the data used are available in Section 2 and Appendix C.1.3.

We relied primarily on MEPS. The individual-level data contain information on Veteran status (but does not include information on service era), age, sex, race/ethnicity, marital status, education, and income. Health information is obtained using open-ended questions about medical conditions present during the past year. These open-ended responses are then collapsed into ICD-9 codes.

MEPS is the only publicly available data source from which we could estimate diagnosed prevalence rates for all Veterans (who are defined based on self-report of being honorably discharged by the military). We inferred whether an individual in MEPS is a VA patient based on the respondents' source of payment for health care. Specifically, we defined active VA patients as those respondents who had any payment by VA for services used. Unfortunately, MEPS data did not enable us to identify all Veterans who are eligible for VA services; we could identify only those eligible Veterans who use VA services. There were also some specific conditions for which MEPS was incapable of providing reliable estimates due to sample size limitations; these primarily consisted of relatively rare conditions, such as polytrauma, TBI, and medically unexplained illness.

We augmented MEPS with two administrative data sources. VA encounter data include individual-level information on diagnoses, demographic characteristics, and geographic location (state). VA encounter data are used to estimate current and prior condition prevalence patterns among active VA patients. This data set has larger sample sizes than MEPS, which allowed us to estimate the prevalence of service-connected health conditions that have a low prevalence rate

---

in the national population. A limitation of the VA encounter data is that the data only include information on VA patient encounters and may miss diagnoses and conditions that were treated in non-VA settings. This includes Veterans not enrolled in VA, Veterans who were enrolled but did not use VA services in the survey year, and Veterans who were only partially reliant on VA. We therefore consulted the existing literature to find estimates of the prevalence of particular conditions. These instances are noted in the text. We also used MHS encounter data, which include information on the diagnoses and demographic characteristics of active component military personnel. The prevalence of health conditions among separating personnel predicts the health conditions of the newest Veteran cohorts and VA patients.

5.2.2 Analytic Approach

The main analyses in this section focus on comparisons of the prevalence of diagnosed health conditions between populations and on projections of health conditions among Veterans. We compared diagnosed prevalence rates between Veterans and non-Veterans, and between VA patients and non-VA patients. We made projections for both the general Veteran population and the VA patient population. A full description of the methods can be found in Appendix C.1.5.

Ideally, to understand the relative health care needs of Veterans versus non-Veterans and VA patients versus non-VA patients, we would estimate the underlying ("true") prevalence of health conditions for each population. Such estimates would allow us to assess more accurately the unique health care needs of Veterans and to understand how changes in where Veterans access care will affect the care they receive and the demands on health care service providers, including VA. However, it is not possible to measure underlying health status and undiagnosed conditions, so we focus on the prevalence of diagnosed health conditions.

The diagnosed prevalence rates are determined by the underlying prevalence of health conditions, access to/use of health care, and the propensity of the health care providers to diagnose particular conditions. For example, if Veterans are more likely to seek health care services than non-Veterans because they are more likely to have health insurance coverage (Section 3), their underlying health conditions will be diagnosed at higher rates. On the provider side, VA specializes in Veterans' health care, so VA staff may be more likely to recognize health conditions that are significant for the Veteran population but are relatively rare in the non-Veteran population (e.g., PTSD) and diagnose these at a higher rate. This would cause the diagnosed prevalence rates of such conditions to be higher among Veterans who use VA health care services than among Veterans (and non-Veterans) who seek health care from other providers, even if the underlying prevalence was the same.

With these limitations in mind, we consider three alternative estimates of diagnosed prevalence: (1) unadjusted observed prevalence rates, (2) prevalence rates adjusted to account for the demographic differences between the two populations, and (3) prevalence rates adjusted to account for demographic differences and differences in access to health care. The unadjusted observed prevalence rates (alternative 1) are estimated as the proportion of the population with a particular health condition. The adjusted prevalence rates (alternatives 2 and 3) are estimated with a generalized linear regression model applied to individual-level data

(MEPS, 2006–2012). The demographic-adjusted model includes age, sex, race/ethnicity, census region of residence, an indicator for residence in a metropolitan area (the MSA), and a time trend as predictors of the probability of having each diagnosed health condition. The health access–adjusted model extends the demographic-adjusted model to include educational attainment, health insurance coverage, marital status, and employment/full-time student status. The appropriate approach for estimating prevalence of diagnosed health conditions depends on the question being addressed. We describe what can be learned from each approach for the comparison of Veterans to non-Veterans and VA patients to non-VA patients below.

We first compare disease prevalence among Veterans with non-Veterans to assess the unique health care needs of the Veteran populations. The simple comparison of the observed *diagnosed* prevalence rates among Veterans and non-Veterans provides insights about actual differences in health care needs across the two populations. The differences in diagnosed prevalence rates do not necessarily reflect the differences in the underlying health care needs of Veterans and non-Veterans, but they do represent differences in the conditions that Veterans and non-Veterans are being treated for, and thus shed light on differences in the types of conditions that community and VA health care providers need to be prepared to treat, given status quo policies.

The simple comparison of diagnosed prevalence rates between Veterans and non-Veterans does not allow us to disentangle differences in health status that are due to the different demographic composition of Veterans and non-Veterans or differential access to health care from differences due to other factors. For example, because Veterans are older on average, we would expect higher prevalence rates among Veterans in conditions correlated with age, such as hypertension. For a complete summary of the demographic differences between Veterans and non-Veterans, see Section 5.3.1 and Appendix C.2.3.

In order to identify the unique health care needs of Veterans, it is therefore necessary to adjust statistically for these differences in demographic characteristics. Adjusted rates allow us to compare prevalence among non-Veterans and Veterans who "look alike" based on their demographic characteristics (age, sex, race/ethnicity, and residential location, as described above). We did this by predicting the prevalence of each health condition among Veterans and non-Veterans with the same demographic characteristics. Adjusted estimates use the Veteran population as our reference population, so that adjusted non-Veteran prevalence rates are predicted "as if" non-Veterans had the same demographic characteristics as Veterans. Therefore, we can attribute any differences remaining after adjustment to factors other than the demographics we include in our model (e.g., military service or deployment, environmental risks, occupational health risks, and unobserved individual-level characteristics that underlie the decision to join the armed forces, such as sense of duty to the country). This provides insight into health conditions that are unique to Veterans and not simply attributable to the demographic composition of the Veteran population.

Finally, to try to estimate diagnosed prevalence rates that are closer to the underlying prevalence of each health condition, we also adjust for such factors as health insurance, employment, and education (as described above), some of which are likely related to health

---

care access and use. However, the results from this approach are difficult to interpret. Unlike the basic demographic characteristics, these additional controls are potentially influenced by the experience of being a Veteran, by DoD and VA policies, and by individual health status. For example, access to health care coverage may be associated with better or worse health, and differentially so across Veterans and non-Veterans. VA specifically targets health coverage to Veterans with worse health outcomes (e.g., service-connected disabilities), ensuring that health coverage is available. On the other hand, health insurance coverage is often tied to employment, so non-Veterans who find it difficult to work due to a health condition will be less likely to have health insurance coverage. For these reasons, we focus on the adjusted model that controls for demographic characteristics only. However, we provide results for the extended model that also controls for health care access in Appendix C.3. In practice, the two adjusted models produce very similar results.

Similarly, comparisons between VA patients and non-VA patients are made using both unadjusted and adjusted prevalence estimates. The reference population for the adjusted prevalence remains the entire Veteran population. All comparisons made between VA patients and non-VA patients using adjusted prevalence account for the different demographic composition of the two populations. Therefore, we can attribute any remaining differences after adjustment to factors other than the demographics we include in our model. As with Veterans, the unadjusted prevalence rates are the best indicators of the current health care needs among each population and the needs facing the health care providers that serve these populations. The adjusted prevalence rates allow us to better understand the disproportionate prevalence of health conditions among VA patients after controlling for predisposing demographic characteristics.

We projected the future prevalence (and counts) of key health conditions among *Veterans* in three main steps. First, we projected forward the Veteran population, categorized by demographic group, as described in Section 3. Second, we projected forward the prevalence of key health conditions, categorized by demographic group using MEPS. We also incorporated a nonlinear trend to account for unobservable trends in risk factors. See Appendix C.1.5 for details. Finally, we multiplied the number of Veterans in each demographic group by the corresponding prevalence to yield the projected number of Veterans with a particular health condition from 2015–2024.

We also projected the future prevalence (and counts) of key health conditions among *VA patients* in four main steps. First, we projected the Veteran population forward, categorized by demographic group, as described in Section 3. Second, we projected forward the number of VA patients, categorized by demographic group in Section 4. Third, we projected forward the prevalence of key health conditions, categorized by demographic groups using MEPS and VA encounter data. We also incorporated a nonlinear trend to account for unobservable trends in risk factors. Finally, we multiplied the number of VA patients in each demographic group by the corresponding prevalence to get the projected number of VA patients with a particular health condition from 2015–2024. See Appendix C.1.5 for details.

5.3 Current Health Care Needs of Veterans and Non-Veterans

In this subsection, we present the estimates of the prevalence of select health conditions among Veterans and non-Veterans using the most recent data available. There are several data limitations that should be kept in mind when viewing the results. Most of the results reported here use ICD-9 diagnosis codes in MEPS data to determine each individual's health conditions. These ICD-9 codes were derived from professional coders' abstractions of respondents' interviews; they are not derived from claims. Prevalence rates may be underestimated in respondents with limited access to health care, who may not know which conditions they have (see Appendix A for further discussion). In addition, ICD-9 codes do not indicate severity of illness or the complexity of a patient's situation. Fully analyzing the severity and complexity of patients' conditions would have required abstracting medical records, a task that was not possible given data constraints and the time frame available to complete this report. MEPS does not include information about service era or service-connected disability, so we are not able to look at differences in the prevalence of health conditions along these dimensions.[29] However, MEPS is the only data source that provides health condition information for all Veterans independent of health care provider.

5.3.1 Demographic Differences Between Veterans and Non-Veterans

Veterans and non-Veterans differ not only by military service experiences but also by demographic characteristics that are associated with the prevalence of particular health conditions. This subsection evaluates the state of Veterans' health relative to that of non-Veterans. In addition, we identified conditions that disproportionately affect Veterans after accounting for demographic differences between the populations.

Using MEPS data, we also examined the demographic profile of Veterans and non-Veterans (see also Table C-18 in Appendix C), which may explain differences in disease prevalence. We found significant differences in age, sex, and race/ethnicity composition. Veterans and non-Veterans also differ in their geographic distribution.

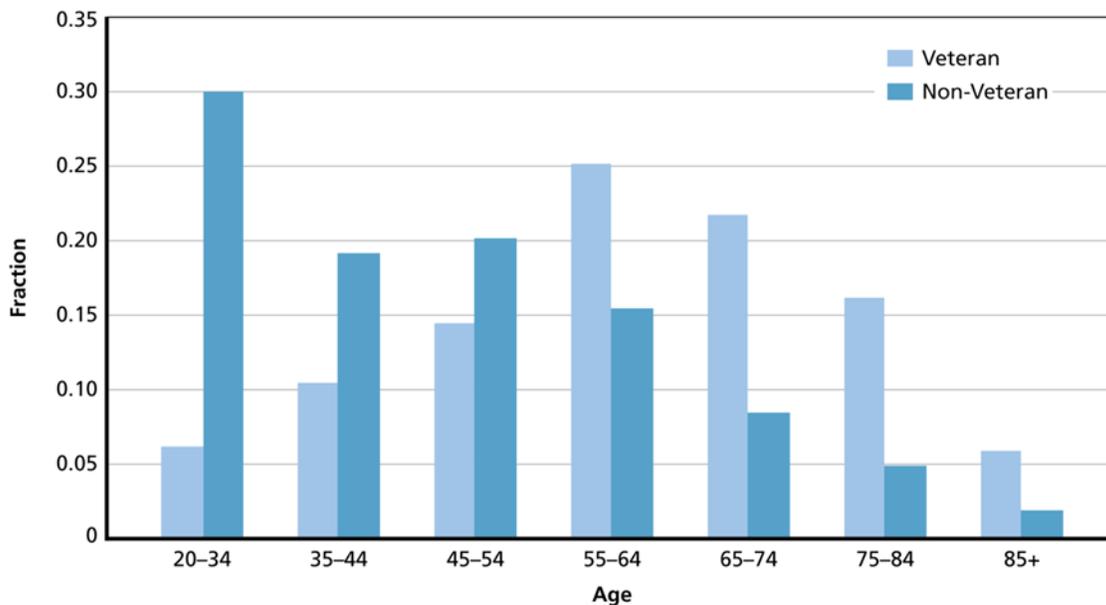
Figure 5-1 shows the age distribution among Veterans and non-Veterans in the MEPS sample. These data demonstrate that Veterans are older; nearly 70 percent of Veterans are age 55 or older, compared with 31 percent of non-Veterans. When we examined the sex composition among Veterans and non-Veterans in our sample, we found that Veterans are predominantly male; more than 93 percent of Veterans are men, compared with 40 percent of non-Veterans.[30] These differences are consistent with those reported by VA (Smith, 2014; U.S. Census Bureau,

---

[29] MEPS began including service era in 2011; however, the Veteran and VA patient sample sizes for 2011 forward were not large enough for this analysis.

[30] The proportion of the non-Veteran population that is male is lower than the proportion of the U.S. population that is male (49 percent) (U.S. Census Bureau, 2014) because it excludes Veterans, who are about 7 percent of the population and 93 percent male (U.S. Census Bureau, 2012a). MEPS also excludes individuals in military and correctional institutions, juvenile institutions, military housing, and other institutions, who are more likely to be male.

2014; U.S. Department of Veterans Affairs, 2014a; U.S. Government Accountability Office, 2009).

Figure 5-1. The Age Distribution for Veterans and Non-Veterans


SOURCE: MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313.

When we compared the race/ethnicity composition of Veterans and non-Veterans, we found that, consistent with tabulations from other sources (Lee & Beckhusen, 2012; National Center for Veterans Analysis and Statistics, 2014c), Veterans are predominantly non-Hispanic white men. In our sample, more than 82 percent of Veterans identified themselves as non-Hispanic white, compared with 66 percent of non-Veterans. Because access to medical services can vary by geographic area, we also included adjustments for Census region of residence. For example, VA has noted that the largest populations of Veterans are in the South (9.9 million) and Midwest (6.1 million) (National Center for Veterans Analysis and Statistics, 2012a). MEPS data include an indicator for whether each respondent resides in an MSA. We used this as a proxy for rural versus urban residence, because previous studies have shown that rural Veterans are different from Veterans living in urban areas. For example, rural Veterans are more likely than urban Veterans to have at least one disability or to have a service-connected disability rating of 50 percent or more (National Center for Veterans Analysis and Statistics, 2012a). MEPS data indicate that about 81 percent of Veterans live in a metropolitan area versus about 85 percent of non-Veterans.

In the next subsection, we present the prevalence of diagnosed health conditions among Veterans and non-Veterans as estimated in MEPS. Differences in demographic characteristics of Veterans and non-Veterans likely account for a substantial proportion of the unadjusted differences in health care needs between the two populations. This comparison provides insights about actual differences in health care needs across the two populations, as discussed

in Section 5.2.2. However, given that we aim to identify the *unique* health care needs of Veterans that result from the total experience of military service, it is important to estimate differences between Veterans and non-Veterans that are not driven by differences in the demographic characteristics of the two groups. Thus, in the remainder of Section 5.3, all comparisons made between Veterans and non-Veterans will use "adjusted" estimates, which are statistically corrected to account for the different demographic composition of the two populations.

There are also socioeconomic characteristics that differ between Veterans and non-Veterans and that may be related to diagnosed disease prevalence through impacts on underlying prevalence, access to health care, or provider type. For example, Veterans are more likely to be married than non-Veterans, a finding that is consistent with previous research documenting higher rates of marriage among military relative to civilian populations (Karney, Loughran, & Pollard, 2012). These additional characteristics are summarized by Veteran and VA patient status in Table 5-1. As discussed in Section 5.2, we do not adjust for these additional differences between Veterans and non-Veterans in our main adjusted model because they may be affected by the experience of being a Veteran and by DoD and VA policies, making the results difficult to interpret. However, we provide results for the extended model that controls for these additional characteristics in Appendix C.3.1. Our baseline adjusted model and the extended model produce very similar results.

Table 5-1. Socioeconomic Characteristics of Non-Veterans, Veterans, Non-VA Patients, and VA Patients in MEPS

Demographic Group	Distribution by Demographic Characteristics (Standard Errors)			
	Veterans	**Non-Veterans**	**Veterans, VA Patients**	**Veterans, Non-VA Patients**
Marital status				
Married	0.659	0.523	0.626	0.680
	(0.009)	(0.004)	(0.010)	(0.011)

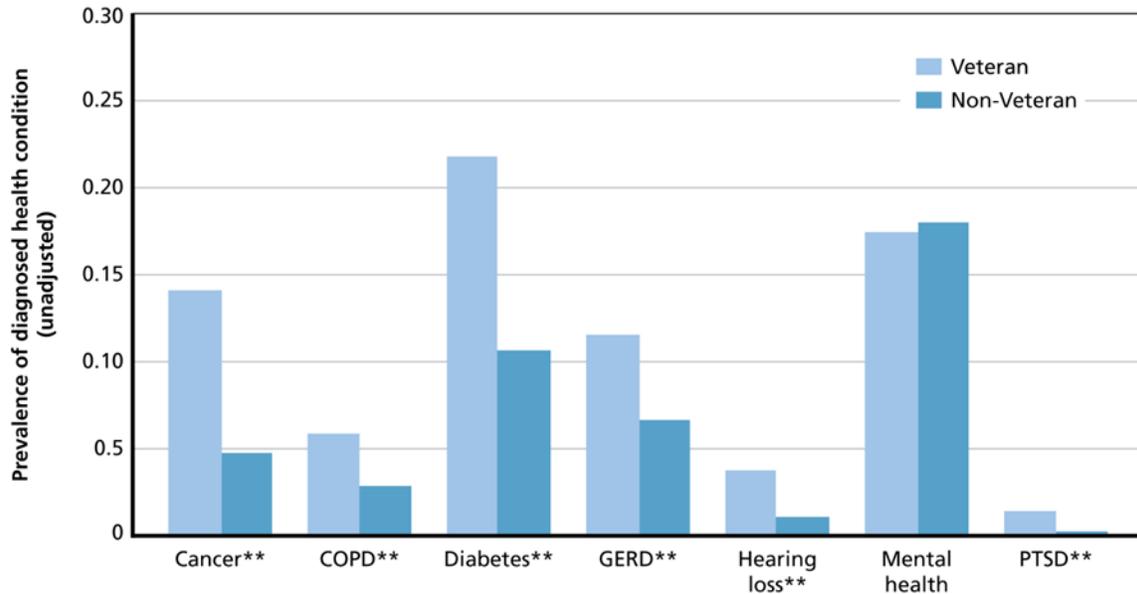
SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Veterans, VA patients and Veterans, non-VA patients are mutually exclusive categories of Veterans. Sample size, Veterans = 12,313; sample size, non-Veterans = 150,225; sample size, VA patients = 4,871; and sample size, non-VA patients = 7,442.

* Non-employed individuals includes both people who are unemployed and people who are out of the labor force, such as retirees.

5.3.2 Prevalence of Health Conditions for Veterans and Non-Veterans

Analysis of MEPS data showed that the diagnosed prevalence of many health conditions is greater for Veterans than non-Veterans. In Appendix C, Table C-6, we list the health conditions examined and report adjusted and unadjusted prevalence rates for Veterans and non-Veterans. Differences in unadjusted prevalence rates vary by condition. For example, the diagnosed prevalence of asthma among Veterans is about 1.4 percentage points lower than among non-Veterans, but the prevalence of hypertension and lipid disorders among Veterans is more than 20 percentage points higher than for non-Veterans. We illustrate the pattern of our findings in Figure 5-2 for a subset of conditions examined. Differences that are statistically different from zero at $p < 0.05$ are marked with two asterisks (**). Except for mental health conditions, Veterans exhibit higher unadjusted prevalence rates than non-Veterans. However, demographic characteristics affect the prevalence of many health conditions; the prevalence of hypertension and many other chronic conditions increases with age, and some conditions are more prevalent in men than in women. In the next subsection, we adjust the prevalence estimates for the demographic differences between Veterans and non-Veterans described in the previous subsection. The difference between the unadjusted and adjusted rates reflects the portion of the differences in prevalence rates that can be explained by demographic differences.

Figure 5-2. Diagnosed (Unadjusted) Prevalence of Selected Health Conditions for Veterans and Non-Veterans


SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. Cancer includes any malignancy, and Mental Health includes any mental health condition.

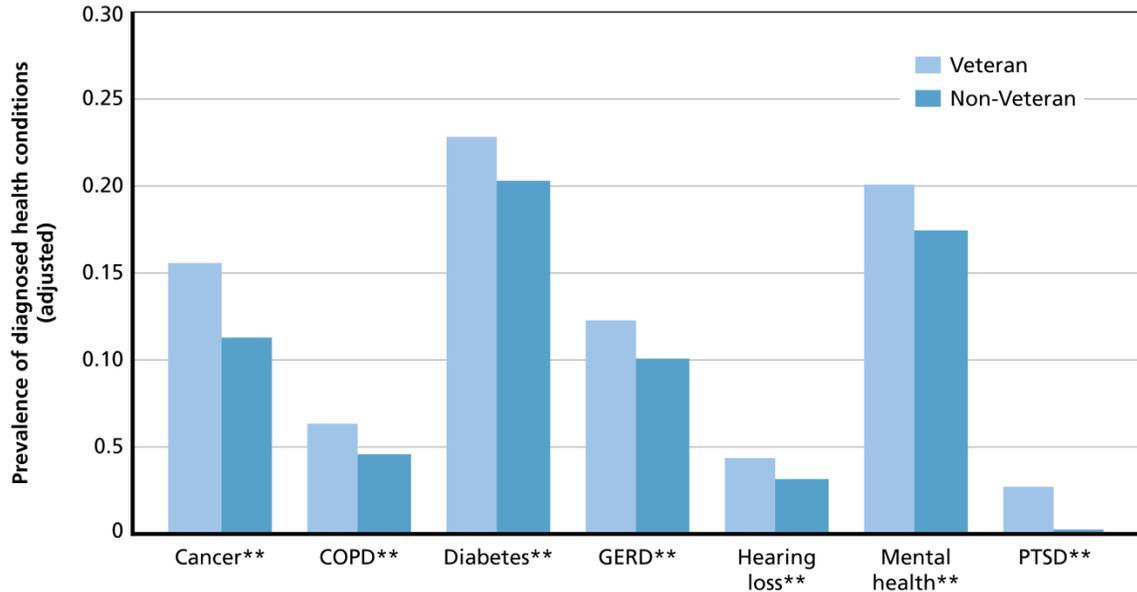
5.3.3 Prevalence of Health Conditions for Veterans and Non-Veterans, Adjusting for Demographic Differences

In this subsection, we present estimates of the prevalence of health conditions for Veterans and non-Veterans, adjusting for a set of demographic characteristics and time trends (changes in disease prevalence over time). We adjusted for age, sex, race/ethnicity, Census region, whether an individual resided in an MSA, and calendar year. We adjusted for age to account for changes in the development of health conditions over the life cycle and for the differential age composition of Veterans and non-Veterans, as seen in Figure 5-3. We adjusted for Census region of residence and whether an individual resided in an MSA to account for the differences in where Veterans and non-Veterans reside. We adjusted for sex and race/ethnicity to account for the demographic differences of Veterans and non-Veterans. Finally, we adjusted for differences in health conditions over time due to secular changes in disease prevalence. For example, a public health campaign to increase awareness of preventive treatments for a particular condition could cause a decline in prevalence that is not related to Veteran status (see Appendix C.2). We refer to this baseline model of adjusted disease prevalence as Model 1.

Overall, we found smaller differences in adjusted diagnosed disease prevalence rates in Model 1 relative to the unadjusted differences, but results still suggest that the adjusted prevalence of many chronic conditions is higher for Veterans than it is for non-Veterans of the same age, sex, and race/ethnicity. Figure 5-3 shows the results for cancer, COPD, diabetes, GERD, hearing loss, any mental health condition, and PTSD (see full results in Table C-6). The

---

largest absolute difference in prevalence is for cancer at 4.3 percentage points, followed by diabetes, mental health conditions, PTSD, and GERD at 2.5 percentage points.

Figure 5-3. Adjusted Diagnosed Prevalence of Selected Health Conditions for Veterans and Non-Veterans


SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. The prevalence rate of each health condition is the predicted prevalence in 2014 for the populations of Veterans and non-Veterans, both with age, sex, race/ethnicity, region, and urbanicity, adjusted to match the demographic composition of Veterans in 2012. Cancer includes any malignancy, and Mental Health includes any mental health condition.

Another way to compare prevalence rates is to examine relative risk of being a Veteran; that is, the prevalence rate for Veterans divided by the prevalence rate for non-Veterans. The largest relative risk in prevalence is for PTSD, which is 13.5 times more prevalent among Veterans than non-Veterans. The prevalence of cancer, hearing loss, and COPD are more than 1.3 times more prevalent for Veterans than non-Veterans. Hypertension, which is excluded from Figure 5-3 due to scale, has the highest prevalence (at 47 percent) for both Veterans and non-Veterans (see Table C-6.)

We examined the full set of estimable health conditions in MEPS. The pattern of results is qualitatively similar to those reported here (see Table C-6). Moreover, the differences in the prevalence of health conditions between Veterans and non-Veterans are not sensitive to different specifications of the statistical model. In a second model, Model 2, we adjusted for additional individual factors, including marital status, education level, employment and student status, health insurance coverage, and interactions between race/ethnicity and sex (see Appendix C.3.1). Differences in predicted prevalence rates are qualitatively similar to those reported here. Model 2 results showed that marriage, college completion, and employment are associated with a lower probability of having been diagnosed or treated for most health conditions. Health insurance coverage is associated with higher probability of having been

diagnosed or treated for most health conditions. This finding is consistent with the notion that insured Veterans and non-Veterans use more health care services than uninsured persons because, in MEPS, measures of health conditions identified by providers reflect only those conditions for which individuals received health care.

Next, we examined the extent to which Veterans and non-Veterans differ in disease burden and comorbidities, based on adjusted differences in the Charlson Comorbidity Index, measures of functional status, and the prevalence of comorbid mental health (a mental health diagnosis in addition to one other diagnosis). Our results are descriptive and not indicative of a causal relationship between Veteran status and comorbidity.

The Charlson Comorbidity Index is a measure that assigns weights to chronic conditions based on their severity (adjusted risk of mortality) or resource use and then is summed to produce an index ranging from zero to 41 (Charlson, Pompei, Ales, & MacKenzie, 1987); having fewer or lower-risk chronic conditions translates into a lower Charlson score, which is in turn correlated with lower risk of death.[31] In Figure 5-4, we report the predicted likelihood that Veterans and non-Veterans have multiple co-morbid or co-occurring conditions based on the Charlson Comorbidity Index. We found that Veterans' and non-Veterans' health had similar index values. This finding holds when we use an indicator of having a Charlson Comorbidity Index greater than one rather than the index value (see Table C-7).

---

[31] The 16 Charlson conditions included in our index are as follows (points/weights in parentheses): myocardial infarction (1), congestive heart failure (CHF) (1), peripheral vascular disease (1), cerebrovascular disease (1), COPD (1), dementia (1), paralysis (1), diabetes (1), chronic renal failure (2), mild liver disease (1), moderate/severe liver disease (3), ulcers (1), rheumatic disease (1), malignant cancer (3), metastatic carcinoma (6), and human immunodeficiency virus (HIV)/acquired immune deficiency syndrome (AIDS) (6).

Figure 5-4. Adjusted Means of Disease Burden Measures for Veterans and Non-Veterans

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. Predicted or adjusted means were obtained from estimating logistic regressions with the following additional covariates included: sex (male is the omitted category), five race/ethnicity categories, 14 age categories, four Census regions, an MSA indicator, and year fixed effects using the margins command in Stata treating Veterans as though they had similar observable characteristics as civilians. The Charlson Comorbidity Index model was estimated using a Poisson regression.

To assess the extent to which Veterans and non-Veterans differ in disease burden, we also examined adjusted differences in functional status. Measures of functional status included the ability to perform self-care tasks, such as bathing and dressing—that is, activities of daily living (ADLs)—and the ability to complete tasks necessary for living independently, including housework, using the phone, and buying groceries—that is, instrumental activities of daily living (IADLs). Veterans were less likely to need assistance with one or more ADLs or with one or more IADLs relative to non-Veterans. Although it may seem counterintuitive, our finding that Veterans are less likely to report an ADL or IADL limitation than non-Veterans is consistent with other studies using data from the Census and the Panel Study of Income Dynamics. For example, one study reported that although Veterans were more likely to have *any* type of disability or limitation, they were less likely to have a memory, personal care (similar to ADL measure), mobility, or work (precluding) disability than non-Veterans (Wilmoth, London, & Parker, 2011). Another study found that non-combat Veterans actually have significantly lower rates of disability than both non-Veterans and combat Veterans (MacLean, 2010). We are unable to distinguish between non-combat and combat Veterans in the MEPS data, but if our sample contains a disproportionate share of non-combat Veterans, this could also explain why we find lower rates of ADL and IADL limitations.

Finally, we investigated adjusted differences in comorbid mental health, the likelihood of having both a mental health diagnosis and any other diagnosis or limitation. Specifically, we estimated whether Veterans were more or less likely to have a mental health diagnosis and

(1) any of the 16 Charlson conditions, (2) any of the other 29 conditions we examined in preparing this section (see Table C-2 for the full list), (3) any ADL limitation, or (4) any IADL limitation. We found that Veterans were nearly 3 percentage points more likely than non-Veterans to have a diagnosed mental health condition and any of the 29 other conditions we examined in this section, but there were no other statistically significant differences. We report these results in Figure 5-5.

Figure 5-5. Adjusted Means of a Comorbid Mental Health Condition (Mental Health Condition + Another Condition/Limitation) for Veterans and Non-Veterans

SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. Predicted or adjusted means were obtained from estimating logistic regressions with the following additional covariates included: sex (male is the omitted category), five race/ethnicity categories, 14 age categories, four Census regions, an MSA indicator, and year fixed effects using the margins command in Stata treating Veterans as though they had similar observable characteristics as civilians.

Our findings are consistent with previous literature that suggests that, compared with non-Veterans, Veterans have worse overall health and higher rates of many health conditions. For instance, male Veterans ages 45–54 are significantly more likely to report being in fair or poor health and to report serious psychological distress than non-Veteran males (Kramarow, 2012). Other studies have suggested that Veterans tend to consume more alcohol, are more likely to smoke, and are less likely to exercise (Bohnert et al., 2012; Centers for Disease Control and Prevention, 2014b; Lehavot, Hoerster, Nelson, Jakupcak, & Simpson, 2012).[32]

We assessed the robustness of our findings that the prevalence of many chronic conditions is higher among Veterans than non-Veterans by carrying out similar analyses of BRFSS and NHIS

---

[32] One exception is that our estimates, using BRFSS (2013), show that Veterans are *more* likely to have exercised in the past 30 days (see Appendix C.3.3.3).

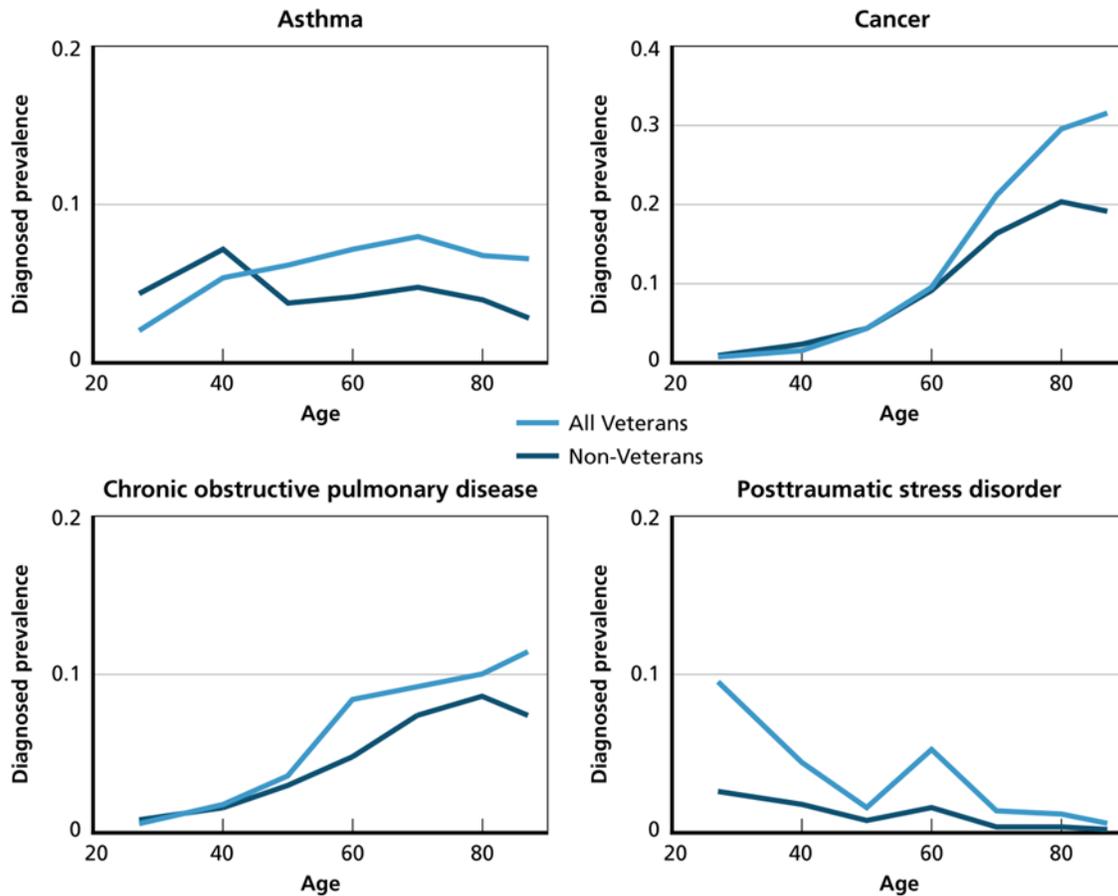
---

under both the basic model and alternative specifications (Appendix C.3). Results from BRFSS and NHIS corroborate findings from analysis of MEPS data.

5.3.4 Heterogeneity by Demographic Characteristics

As discussed, there are significant differences in the health care needs of Veterans and non-Veterans, some of which can be explained by differences in demographic characteristics. In this section, we examine the extent to which diagnosed disease prevalence rates differ across Veterans and non-Veterans within a given age, sex, or race/ethnicity category. In Figure 5-6, we illustrate how differences in the prevalence of chronic conditions between Veterans and non-Veterans vary by age. The selected conditions are those for which the overall prevalence for Veterans is statistically higher than the prevalence for non-Veterans and for which there is evidence that the difference varies across age groups. Asthma exhibits similar patterns for both Veterans and non-Veterans, except that it is slightly lower for younger Veterans (< 45 years). Differences in diagnosed disease prevalence across Veterans and non-Veterans across age categories reflect both the changing relative health status with age and differences by service cohort, which is highly correlated with age. The lower prevalence of asthma observed among younger Veterans is consistent with the physical requirements for enlisting in the military (Boyle, 2014). The difference in the prevalence of cancer between Veterans and non-Veterans is statistically higher for those 65 and older, but not in younger age groups. The difference in the prevalence of COPD appears to grow with age, but the trend is not statistically significant. For PTSD, the difference in prevalence (statistically significant) is highest for the 20–34 age-group, and it decreases for the 35–44 and 55–64 cohorts.

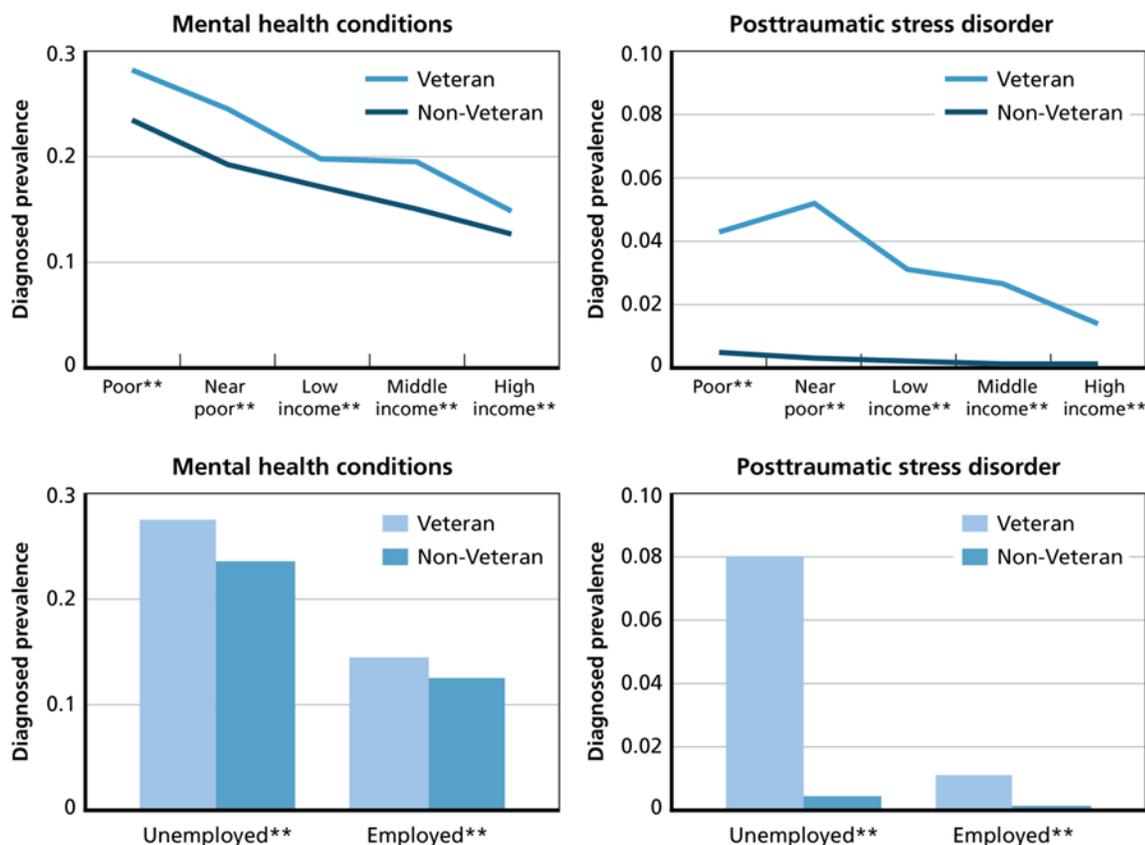
We also found differences in disease prevalence by sex, race/ethnicity, and geographic area of residence (see Appendix C.2.1, Tables C-9 and C-10 for the full set of results). Among men, diagnosed disease prevalence rates are typically greater for Veterans relative to non-Veterans, whereas this is not consistently the case among women. For most health conditions, the prevalence rates are similar across race/ethnicity groups. We observe differences for cancer and mental health conditions, including PTSD. Veterans living in a metropolitan area tended to have greater diagnosed disease prevalence rates relative to their non-Veteran counterparts for most conditions. Whether these differences exist because access to care may be different across rural and urban areas or because sicker Veterans needing care may live in urban areas is unclear.

Figure 5-6. Prevalence of Selected Diagnosed Health Conditions for Veterans and Non-Veterans, by Age


SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. The adjusted prevalence rates are the predicted prevalence from a logit estimation that included indicators for sex, five race/ethnicity categories, seven age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. These estimated differences control for the demographic differences between Veterans and non-Veterans and across age groups. Cancer includes any malignancy.

Previous studies have suggested that while the overall difference in unemployment rates for Veterans and non-Veterans is similar, there is notable variation by era of services and age; for example, 59 percent of unemployed Veterans are younger than 45 (Bureau of Labor Statistics, 2015). Veterans, accounting for approximately 10 percent of the adult population, represent a disproportionate share of the homeless adult (16 percent) and sheltered homeless adult (13 percent) populations (National Center for Veterans Analysis and Statistics, 2012b). Thus, we considered whether poverty, income, and employment status were associated with differences in prevalence of health conditions between Veterans and non-Veterans (Table C-11). We used the MEPS categorical measure of poverty based on family income as a percentage of the poverty line (poor or negative income, near poor, low income, middle income, and high income). In Figure 5-7, we show that unemployed Veterans tend to have higher prevalence rates of most conditions relative to unemployed non-Veterans, but employed Veterans also

tend to have greater disease prevalence relative to their employed non-Veteran counterparts. The figure presents the results for mental health and PTSD. The prevalence of any mental health condition and PTSD were higher by approximately 4 percentage points for Veterans who were categorized as poor based on family income.

Figure 5-7. Difference in the Prevalence of Diagnosed Health Conditions for Veterans and Non-Veterans: Vulnerable Populations


SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between Veterans and non-Veterans at p-value < 0.05. Sample size, non-Veterans = 150,225, and sample size, Veterans = 12,313. We use the MEPS categorical measure of poverty based on family income as a percentage of the poverty line. The adjusted prevalence rates are the predicted prevalence from a logit estimation that included indicators for sex, five race/ethnicity categories, seven age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. These estimated differences control for the demographic differences between Veterans and non-Veterans and across age groups.

Using NHIS data, we investigated the extent to which there were significant differences in financial insecurities for Veterans and non-Veterans. Specifically, we examined the differences in the probability of being moderately to severely worried about paying bills, health care costs, and housing costs, and in participation in the Temporary Assistance for Needy Families program for Veterans and non-Veterans. Generally, the probability of being moderately to severely worried about financial insecurities was lower for Veterans than non-Veterans (Panel A of Table C-12). These findings persisted when we focused on those individuals reporting any chronic

condition (Panel B of Table C-12) or a health problem requiring special equipment (Panel C of Table C-12).

5.3.5 Prevalence of Rare Health Conditions and Other Risks Among Veterans

Due to the relatively small sample size of Veterans in MEPS, we could not include rare conditions in our analysis. To fill this gap in the preceding analysis, we briefly discuss the results of other studies to provide a more complete picture of the unique health care needs of Veterans; of note, the studies did not compare prevalence rates between Veterans and non-Veterans, so we cannot comment on whether these conditions disproportionately affect Veterans.

We highlight injuries and conditions that are more likely to be prevalent among Veterans due to their association with military service. The unique nature of combat in Afghanistan and Iraq, including improvised explosive devices, is associated with severe combat injuries, including amputation, burns, spinal cord injury, and TBI. The survival of injured Afghanistan and Iraq Veterans is approximately 90 percent, due in part to improvements in medical care and protective gear (Golding, 2011). The prevalence of serious injuries remains low; however, these Veterans have complex long-term health care needs.[33] From 2001 to 2010, there were approximately 1,500 amputations among service members who served in Afghanistan, Iraq, and unaffiliated conflicts, 1,200 of which were major limb amputations (Fischer, 2010). TBI has been labeled a "signature injury" for the Afghanistan and Iraq conflicts (Taylor et al., 2012), and while there may be a deployment-related risk for experiencing a TBI (such as being exposed to blast explosions), service members may also experience a TBI in non-deployed settings. Between 2000 and 2014, more than 300,000 service members were diagnosed with TBI (U.S. Defense and Veterans Brain Injury Center, 2014). TBI frequently occurs in conjunction with polytrauma and other disabling conditions, such as amputation, burns, spinal cord injury, auditory and visual damage, spinal cord injury, and PTSD.[34] Based on an analysis of VHA administrative data from 2004 to 2009, approximately 5 percent of Veterans treated by VA were diagnosed with both PTSD and TBI. This polytrauma occurred in 75 percent of diagnosed TBI cases and in approximately 20 percent of diagnosed PTSD cases (Congressional Budget Office, 2012).

Medically unexplained illnesses—also referred to as "chronic multisymptom illness" and formerly known as Gulf War Syndrome—are a critical concern for many Veterans who served during the 1990–1991 Gulf War. Medically unexplained illnesses involve a cluster of medically

---

[33] Several DoD databases record information on battlefield injuries or medical care that is delivered in theater that would allow for a study of the type of care that is needed for patients who would not have survived their injuries in previous conflicts. However, examination of these sources was beyond the scope of this analysis. In some cases, additional clinical work would be required to determine whether the patient would have died from injuries in previous conflicts. In all cases, data constraints in this particular study prohibited a linked analysis of theater records with subsequent care delivered by VA. For instance, DMDC maintains data on casualties that occurred during the conflicts in Iraq and Afghanistan. Joint Trauma System also maintains a DoD Trauma Registry that contains information on health care delivered to trauma cases in theater.

[34] Polytrauma occurs when a person experiences injuries to multiple body parts and organ systems, often as a result of a blast.

---

unexplained chronic symptoms—such as fatigue, headaches, joint pain, indigestion, insomnia, dizziness, respiratory disorders, and memory problems—that Veterans attribute to their deployment (Institute of Medicine of the National Academies, 2014a). Survey data from 1999 and 2001 showed a prevalence of 28.9 percent of Veterans deployed during the Gulf War period, compared with a prevalence of 15.8 percent among Veterans who were not deployed (Blanchard et al., 2006).There are also several diseases that warrant special attention among Veterans. In 2011, VA cared for more than 25,000 Veterans with HIV/AIDS (U.S. Department of Veterans Affairs, 2012), and VA is the nation's largest single provider of HIV health care (U.S. Department of Veterans Affairs, 2011). Wang et al. (2015) found a total of 25,648 VA users ages 18–64 who had been diagnosed with HIV from 2007–2012, of which 11,371 had not been previously treated with anti-retroviral therapy. Chronic hepatitis C, caused by the hepatitis C virus, is a recognized public health issue among Veterans (Zuniga, Chen, Lane, Allmer, & Jimenez-Lucho, 2006). Among the 5.6 million Veterans accessing care in the VA system in 2008, prevalence was 2.6 percent (Office of Public Health and Environmental Hazards, 2010).

Suicide and substance abuse are two important risks for the Veteran population. Suicide risk is elevated for those who have participated in military service, particularly for males, who are at a higher risk of suicide compared with non-Veterans in all age groups except the oldest (Kaplan, McFarland, Huguet, & Valenstein, 2012). A population-based study of pre-9/11 male Veterans also found that Veterans were at an increased risk of suicide compared with non-Veterans (Kaplan, Huguet, McFarland, & Newsom, 2007). Veterans engage in higher rates of alcohol use than civilians. The prevalence of heavy drinking (consuming on average at least 15 drinks per week in the prior year) and smoking is higher among Veterans ages 25–74 compared with non-Veterans (Centers for Disease Control and Prevention, 2014b, 2015; Lehavot et al., 2012).

5.4 Current Health Care Needs of Veterans, by VA Patient Status

Veterans' use of VA health care depends on many factors, including service experience, socioeconomic status, and health insurance options. This section considers how VA patients[35] differ from other Veterans in their health care needs to understand current demand for VA health care services and to project the health care needs of the VA patient population through 2024. As in Section 5.3, we present estimates of the prevalence of selected health conditions using the most recent data available, and most of the results reported here use ICD-9 diagnosis codes in MEPS data to determine each individual's health conditions, which may underestimate

---

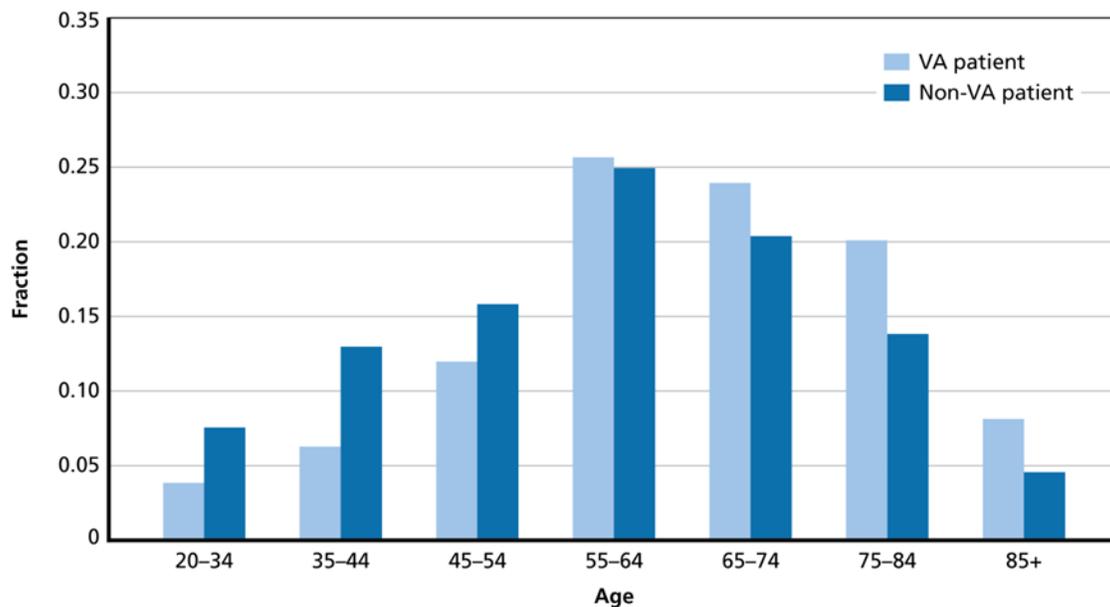
[35] VA patients are Veterans identified in MEPS as having any health care expenditures paid for by VA or the Civilian Health and Medical Program of the Department of Veterans Affairs (CHAMPVA). Medical expenditures in the MEPS data are derived from both household survey information and information provided from the medical provider component (if available). They include direct payments for care provided during the year (payments both out of pocket and by insurance or other sources). As noted, the medical provider component includes data collected from a sample of office-based visits to physicians, hospital visits, and prescription drugs. If this information was incomplete or a respondent did not consent to contacting providers, then expenditures were based on household reports. In this analysis, we denote Veterans (honorably discharged and not on active military duty) who have any medical expenditures paid for by the "Veterans Administration/CHAMPVA, excluding TRICARE (VA)" as "VA patients." For more details on the expenditure data in MEPS, see Medical Expenditure Panel Survey, 2014, Section 2.5.11.

prevalence among respondents with limited access to health care. We supplement the MEPS analysis with analysis of VA encounter data and MHS encounter data. Like MEPS, VA encounter data do not include information about service era.[36] We cannot address differences in health care needs by service-connected disability using MEPS, but we do provide results by priority group using VA encounter data. A limitation of the estimates using VA encounter data is that many Veterans use non-VA providers of health care services. The VA administrative data include only conditions diagnosed or treated at VA, so comorbidity analysis would be difficult to interpret.

5.4.1 Demographic Differences by VA Patient Status

There are some differences in the demographic composition of the VA patient population and the population of Veterans who do not use VA services. Most notably, the VA patient population is older, as seen in Figure 5-8. The difference in the proportion of VA patients and non-VA patients in each age group is statistically different in all but the 55–64 age group. We briefly highlight the key findings here, but we report differences across other demographic characteristics in Appendix C.2.3, Table C-18. The percentage of VA patients who are male (94 percent) is not statistically different from the percentage of non-VA patients who are male (93 percent). The percentage of the VA patient population that is black (non-Hispanic) is slightly higher and the percentage that is Asian is slightly lower than the non-VA patient population. It is unlikely that differences in disease prevalence by race/ethnicity or sex are driving the large differences in the disease prevalence by VA patient status.

**Figure 5-8. Age Distribution of Veterans, by VA Patient Status**

---


[36] MEPS began including service era in 2011; however, the Veteran and VA patient samples sizes for 2011 forward were not large enough for this analysis.

SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values.

Differences in demographic characteristics may explain some proportion of the unadjusted differences in health care needs between Veterans and non-Veterans. Following our earlier analyses comparing Veterans and non-Veterans, we adjusted prevalence rates for VA patients and non-VA patient Veterans to account for these demographic differences.

There are also differences in the socioeconomic characteristics of VA patients and non-VA patients that may be related to diagnosed disease prevalence (Table 5-2). VA patients are older, have lower incomes, are less likely to be employed, and are less likely to be married than Veterans who do not use VA health care.

Table 5-2. Socioeconomic Characteristics of Veterans by VA Patient Status, 2006–2012

Characteristic	Veterans, VA Patients	Veterans, Non-VA Patients
Over age 65	52.2%	38.7%
Married	62.6%	68.0%
Less than high school education	9.1%	5.8%
Employed*	41.3%	62.8%
Average household income	$35,981	$45,278

SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: Veterans, VA patients and Veterans, non-VA patients are mutually exclusive categories. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442.
* Non-employed individuals include both people who are unemployed and people who are out of the labor force, such as retirees.

5.4.2 Prevalence of Health Conditions of Veterans, by Use of VA Health Care Services

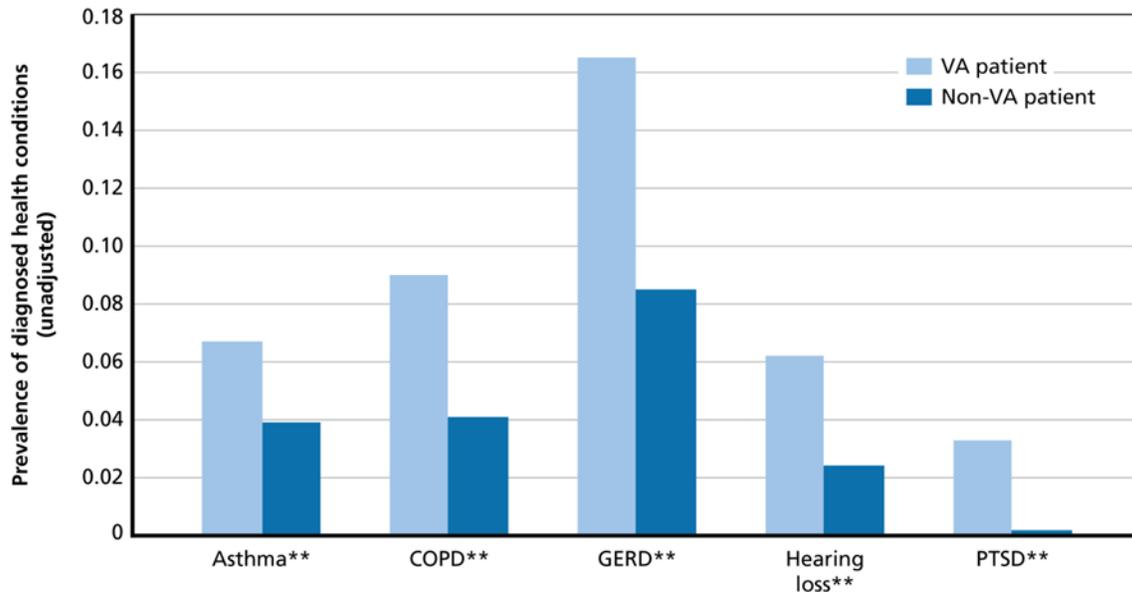
The results from the previous subsection showed that the prevalence of most health conditions is higher for Veterans than for non-Veterans, even after adjusting for demographic composition of these two populations. The analysis also showed that there is variation within Veterans across some demographic characteristics, such as age. In this section, we compared diagnosed disease prevalence rates between VA patients (as defined above) and Veterans who have not had any medical expenditures paid for by VA or CHAMPVA during the past year ("non-VA patients").

In Figure 5-9 and Figure 5-10, we present the results for selected high- and low-prevalence conditions among VA patients and non-VA patients. Conditions are grouped for scaling (see Appendix C.2 for a more comprehensive list of health conditions). The unadjusted prevalence rates of diagnosed diseases are consistently statistically greater for VA patients than for non-VA

patients, both among high- and low-prevalence conditions. Among the high-prevalence health conditions differences in unadjusted diagnosed disease prevalence rates range from 7.7 to 19.5 percentage points (for cancer and hypertension, respectively). Among low-prevalence conditions, differences in unadjusted diagnosed disease prevalence rates range from 2.8 to 8.0 percentage points (for asthma and GERD, respectively).

Figure 5-9. Unadjusted Prevalence of Diagnosed High-Prevalence Health Conditions Among Veterans, by VA Patient Status

SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value < 0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values. Cancer includes any malignancy, and Mental Health includes any mental health condition.

Figure 5-10. Unadjusted Prevalence of Diagnosed Lower-Prevalence Health Conditions Among Veterans, by VA Patient Status


SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value < 0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values.

In the next subsections, we examine the extent to which differences in the demographic characteristics of VA and non-VA patients are driving these results.

5.4.3 Prevalence of Health Conditions, by VA Patient Status, Adjusted for Demographic Differences

As noted in Section 5.4.1, VA patients tend to have greater unadjusted rates of diagnosed diseases relative to Veterans who are not VA patients. Because use of VA health care services may be correlated with key demographic characteristics, we estimated disease prevalence for Veterans who are VA patients and for those who do not use VA services, adjusting for age, sex, race/ethnicity, geographic residence, and time trends (as described for comparisons of Veterans and non-Veterans in Section 5.3.2). Again, we refer to this estimation specification as Model 1.

We present predicted prevalence rates for several key conditions in Figures 5-11 and 5-12, grouped by prevalence level for scale (see Table C-13 for full results). In general, adjusting for demographic characteristics reduced the differences in prevalence rates between VA and non-VA patients, but VA patients still appear to have significantly greater rates of diagnosed diseases. Among high-prevalence conditions, the differences in prevalence rates among VA and non-VA patients range from 5.0 to 16.6 percentage points (for cancer and any mental health condition, respectively). Among low-prevalence conditions, the differences in prevalence rates

range from 3.8 to 8.2 percentage points (for hearing loss and PTSD, respectively). The predicted prevalence of chronic conditions that are potentially related to military service for Veterans exposed to Agent Orange is higher for VA patients (U.S. Department of Veterans Affairs, 2015f).

Figure 5-11. Adjusted Prevalence of Diagnosed High-Prevalence Health Conditions Among Veterans, by VA Patient Status

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value < 0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level. Cancer includes any malignancy, and Mental Health includes any mental health condition.

Figure 5-12. Adjusted Prevalence of Diagnosed Lower-Prevalence Health Conditions Among Veterans, by VA Patient Status

SOURCE: RAND analysis of MEPS, 2006–2012.
NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value < 0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level.

There are several potential factors that may drive the differences in prevalence rates between VA patients and Veterans who do not use VA health care. First, Veterans who use VA health care services may be sicker than Veterans who do not use VA health care. Second, Veterans may be more likely to seek out and use VA health care services if they have health conditions that they believe VA is better equipped to treat, such as PTSD. Finally, VA providers may diagnose some conditions, particularly those that are service-connected, at a higher rate than other health care providers.

We examined the sensitivity of our Model 1 findings by including additional individual-level characteristics, including marital status, educational attainment (four categories), current student status, current employment status, health insurance coverage, and interactions of sex and race/ethnicity (full results are available in Table C-27). Again, we refer to this more detailed estimation specification as Model 2. The gap between VA patients and non-VA patients closes for most conditions using Model 2, except for cerebrovascular disease and lipid disorder, for which the gap widens slightly, and for cancer, hearing loss, and hypertension, for which the prevalence gap remains the same. The largest decrease in gap is observed in the prevalence of any mental health condition, followed by PTSD. Health insurance coverage was associated with a higher prevalence of most conditions, though many of the differences were not statistically different from zero. Having a college degree was associated with lower prevalence rates, particularly for COPD, hypertension, and IHD.

We examined the extent to which VA patients have greater disease burden, as measured by the Charlson Comorbidity Index and the presence of a limitation in IADLs (Figure 5-13). Due to sample size limitations, we were unable to estimate differences in the presence of ADLs across VA and non-VA patients. VA patients were more likely to have at least one Charlson condition and one IADL limitation relative to non-VA patients. Full results are available in Appendix C.2. We also found that VA patients are more likely to have a comorbid mental health condition (Figure 5-14).

NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value < 0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level.

Figure 5-14. Adjusted Means of Comorbid Mental Health Condition (Mental Health Condition + Another Condition/Limitation) for Veterans, by VA Patient Status

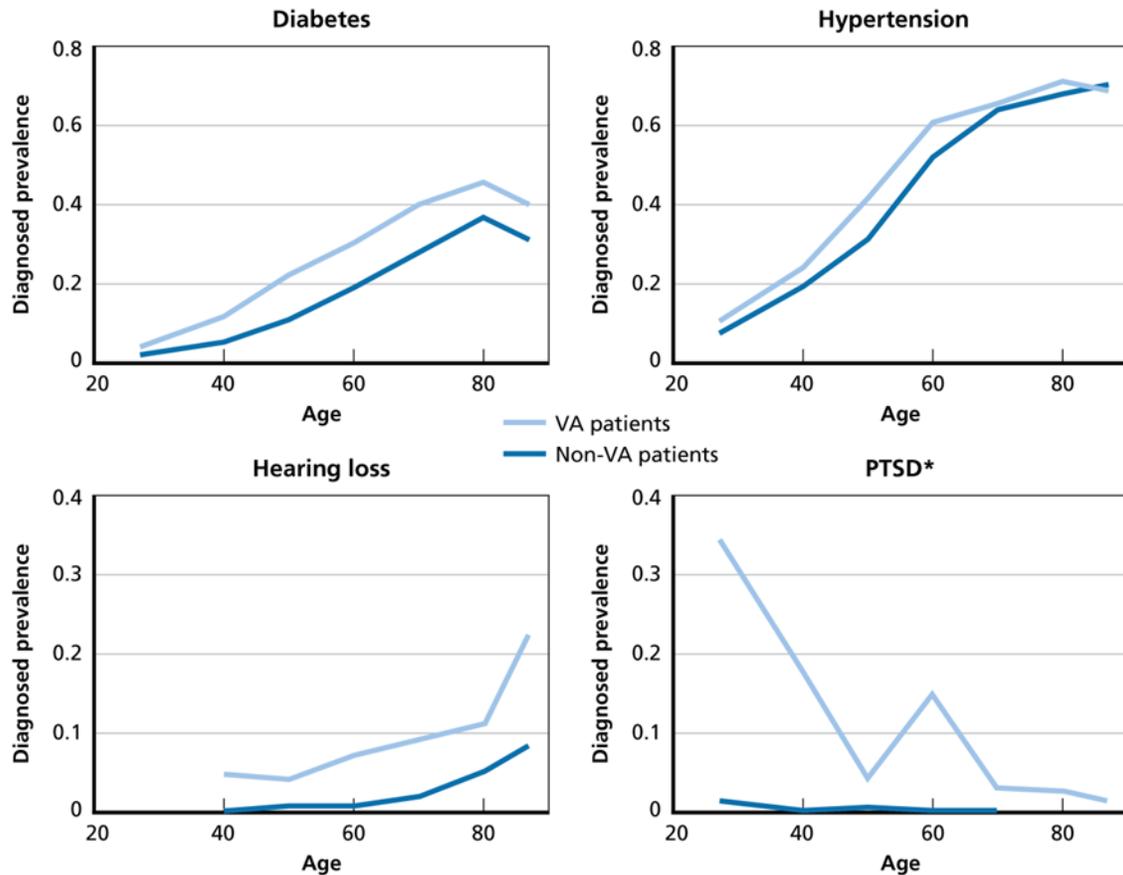
SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: ** indicates a statistically significant difference between VA patients and Veterans who are not VA patients at p-value < 0.05. Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level.

5.4.4 Heterogeneity by Demographic Characteristics

As noted, Veterans who use VA health care services have many health care needs that are distinct from those of Veterans who do not use VA health care services. This section explores how VA patients' health conditions vary by demographic characteristic and how the differences vary by demographic characteristic, including age, sex, and race/ethnicity.

In Figure 5-15, we present adjusted diagnosed disease prevalence for VA patients and for non-VA patient Veterans by age category for diabetes, hypertension, hearing loss, and PTSD (full results are in Tables C-16 and C-17, respectively). The changes in diagnosed disease prevalence of diabetes, hypertension, and hearing loss across the age distribution are similar for both VA and non-VA patients. Veterans using VA services, however, tend to be diagnosed with PTSD at significantly greater rates than non-VA patients, particularly at younger ages and between ages 55 and 64. Given that MEPS data cover 2006 to 2012, these ages align with service in the post-9/11 and Vietnam eras.

Figure 5-15. Prevalence of Selected Diagnosed Conditions Among Veterans, by VA Patient Status and Age


SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Sample size, VA patients = 4,871, and sample size, non-VA patients = 7,442. Sample sizes may be smaller for some conditions due to missing values. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level.

* Due to sample size, prevalence of PTSD among older Veterans who are not VA patients could not be estimated.

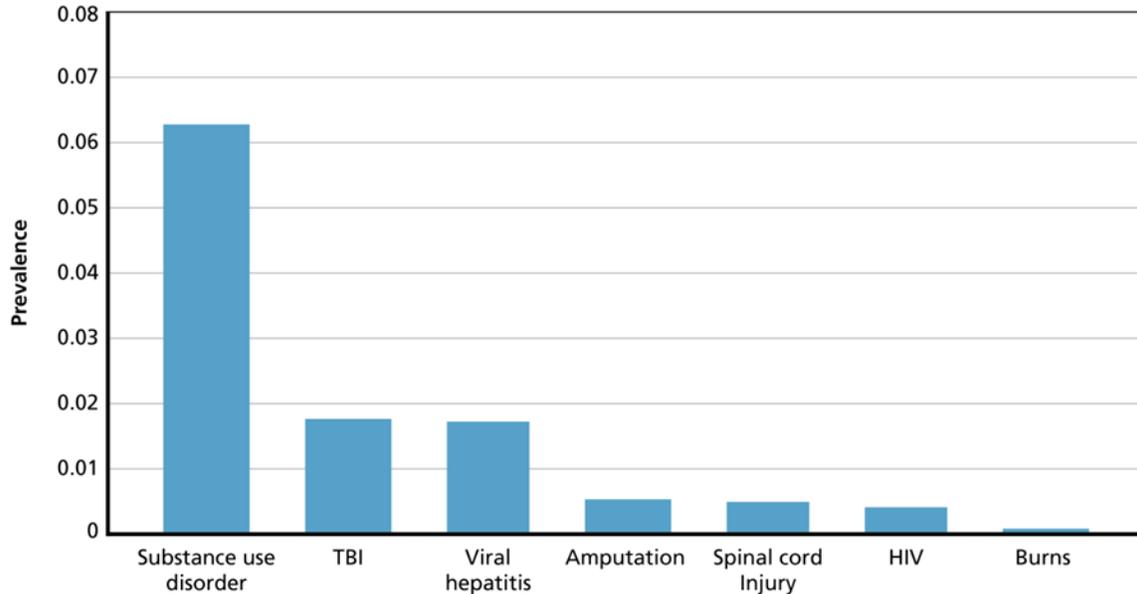
In Appendix C.2.2, Tables C-16 and C-17 show the prevalence of differences by age, sex, and race/ethnicity. Among both women and men, VA patients consistently have higher prevalence of health conditions than non-VA patients.

5.4.5 Prevalence of Rare Health Conditions Among VA Patients

Due to the small sample size of VA patients in MEPS, we could not include rare conditions in our analysis. To fill this gap in the preceding analysis, we utilized VA encounter data to provide a more complete picture of the unique health care needs of VA patients. An important caveat is that prevalence estimates using VA encounter data only capture conditions *treated at VA*. However, as noted in Section 2, most Veterans with service-connected conditions use VA health

---

care services. The unadjusted prevalence estimates using 2014 VA encounter data are presented in Figure 5-16.

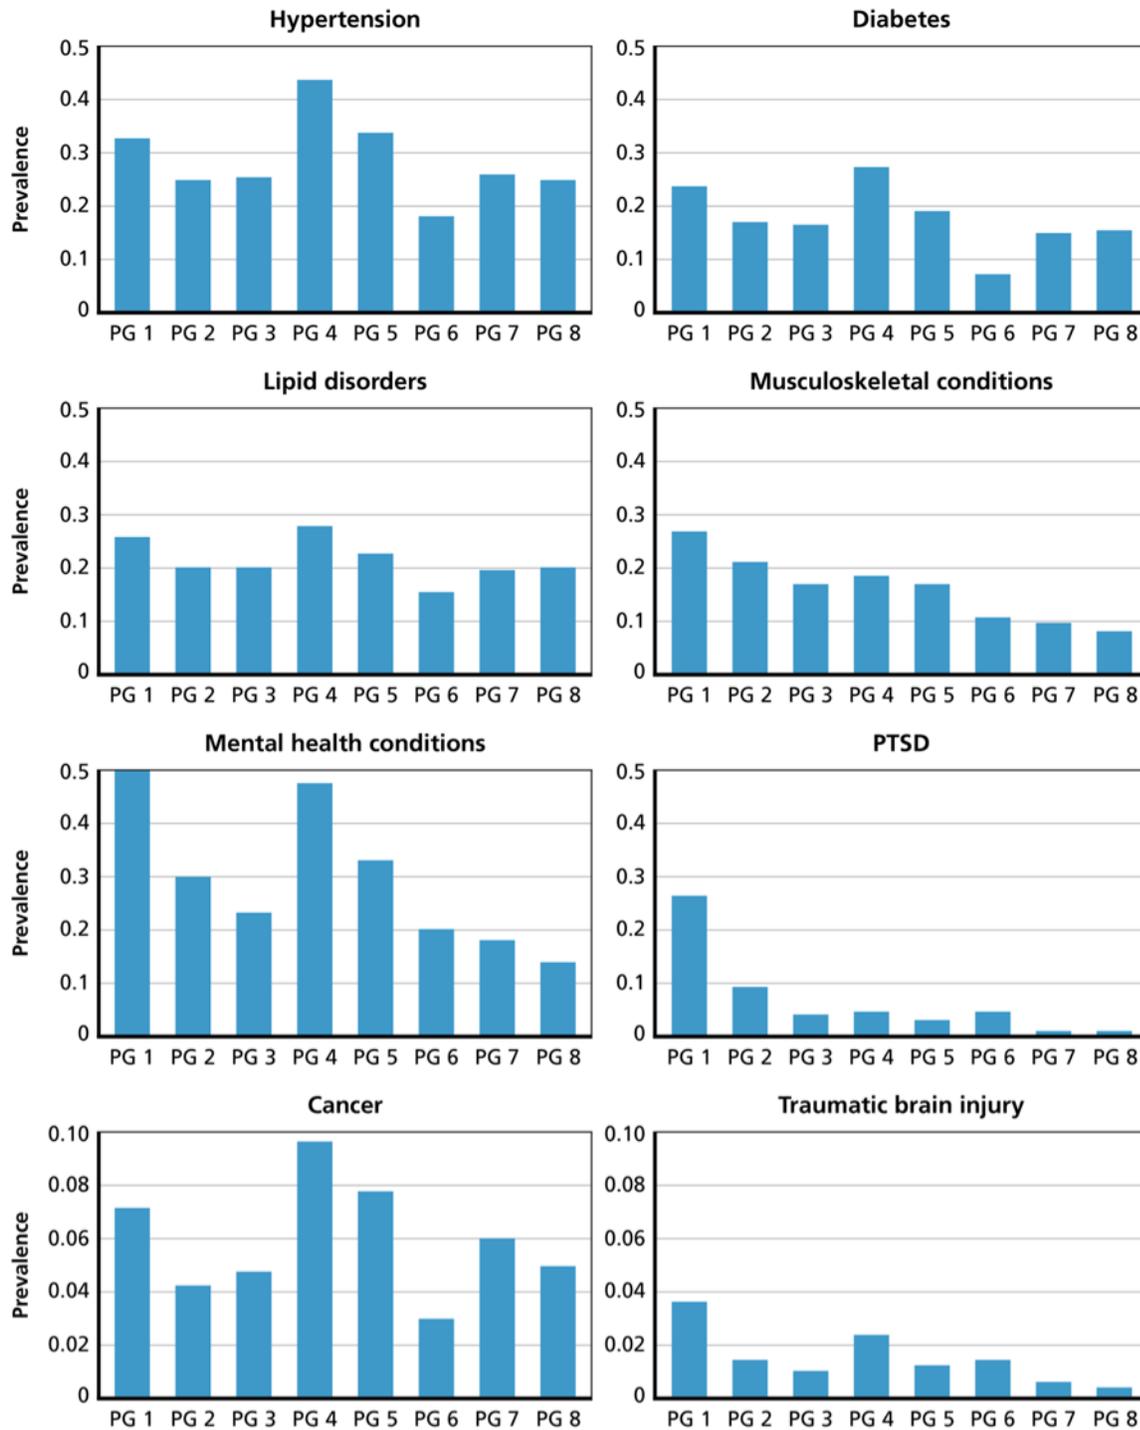
Figure 5-16. VA Encounter-Based Prevalence of Diagnosed Health Conditions Among VA Patients


SOURCE: RAND analysis of VA encounter data (2014).
NOTES: VA encounter sample size, VA patients = 5,871,766.

5.4.6 Prevalence of Health Conditions among VA Patients, by VA Priority Group and Reliance

In this subsection, we explore the associations between the prevalence of health conditions among VA patients and the patients' interactions with VA. Specifically, we consider the prevalence of health conditions by priority group and one measure of VA reliance.

It may also be informative to understand how the health conditions of VA patients vary by priority group. Figure 5-17 shows the prevalence of selected health conditions among VA patients in 2014, by priority group (PG), and Table C-20 shows the full results. These prevalence estimates are based on VA encounter data, so they capture only the *VA-diagnosed* prevalence rates, which may be different from the total prevalence rates based on diagnosis independent of provider. The estimates show that prevalence for hypertension, diabetes, and cancer are highest among VA patients in priority group 4. This could be because these patients have higher rates of disease or because they are more reliant on VA health care services. We cannot disentangle the two. Not surprisingly, PTSD and TBI, which are highly connected to service, have the highest prevalence among VA patients in priority group 1.

Figure 5-17. VA Encounter-Based Prevalence of Diagnosed Health Conditions, by Priority Group


SOURCE: RAND analysis of VA encounter data (2014).
NOTES: VA encounter sample size, VA patients = 5,871,766.

In Table 5-3, we use MEPS data to explore how VA patients whose medical expenditures are paid only by VA differ from VA patients who have some health expenditures paid by other sources of health coverage (e.g., Medicare). We define VA patients as "VA reliant" if all medical expenditures, independent of provider, were VA paid or VA and self or family paid. According to our estimates using MEPS, approximately 13 percent of all VA patients can be classified as reliant. VA-reliant patients are younger than those who also use other sources of health coverage (Appendix C-21).

Due to demographic differences between the two groups, we present adjusted prevalence rates in Table 5-3. The results suggest that even after adjusting for differences in characteristics that may be related to disease prevalence, the prevalence rates for some health conditions, including diabetes, GERD, and cancer, are lower for VA-reliant patients than other VA patients. However, it is difficult to draw any inferences from these estimates because they are imprecise due to the small sample size of VA reliant patients.

Table 5-3. Prevalence of Diagnosed Health Conditions among VA Patients, by VA Reliance

Health condition	All Ages		p-value of Difference	Age < 65		p-value of Difference
	VA Reliant (13%)	VA Non-Reliant (87%)		VA Reliant (20%)	VA Non-Reliant (80%)	
Cancer	0.115 (0.026)	0.210 (0.030)	< 0.000	0.062 (0.022)	0.113 (0.039)	0.064
COPD	0.120 (0.029)	0.105 (0.024)	0.423	0.098 (0.037)	0.075 (0.030)	0.239
Diabetes	0.267 (0.037)	0.350 (0.036)	0.001	0.223 (0.047)	0.288 (0.051)	0.035
GERD	0.116 (0.025)	0.180 (0.032)	0.003	0.110 (0.033)	0.158 (0.044)	0.072
Hearing Loss	0.093 (0.031)	0.092 (0.024)	0.971	0.071 (0.045)	0.085 (0.037)	0.566
Mental Health Conditions	0.273 (0.037)	0.321 (0.036)	0.050	0.358 (0.055)	0.411 (0.055)	0.107
PTSD	0.081 (0.025)	0.078 (0.022)	0.821	0.119 (0.039)	0.118 (0.038)	0.973

SOURCE: RAND analysis of MEPS, 2006–2012.

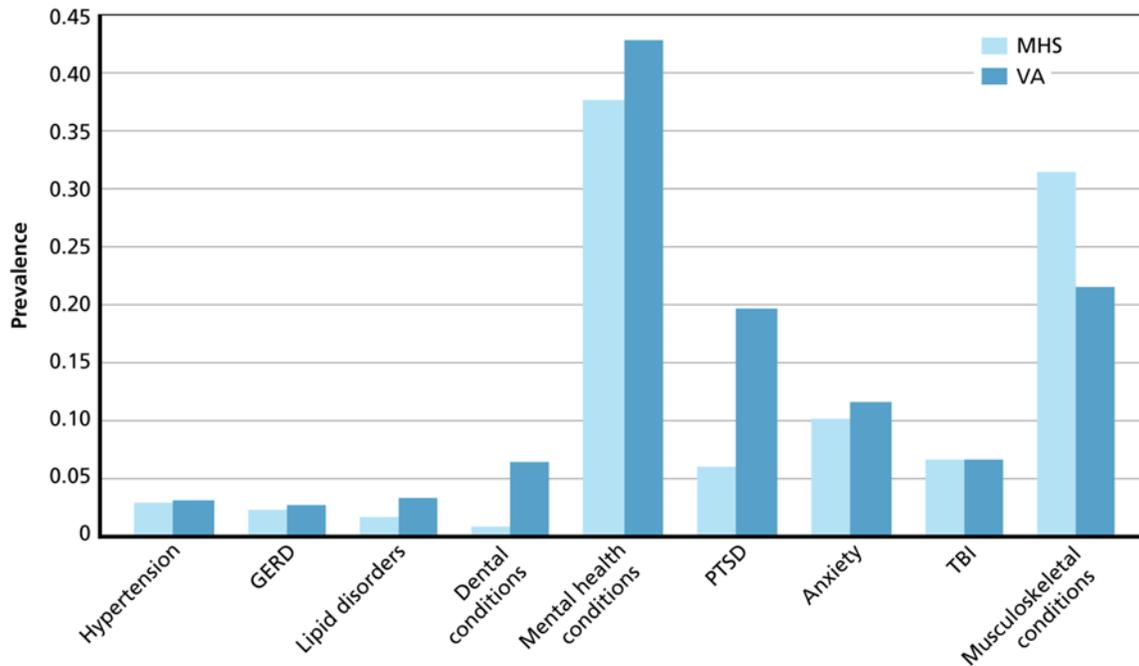
NOTES: ** indicates a statistically significant difference between VA-reliant patients and VA non-reliant patients at p-value < 0.05. Sample size, VA patients = 4,871; VA-reliant patients = 740; VA non-reliant patients = 4,131. A VA patient is considered reliant if all medical expenses in the year were VA and family/self-paid. A VA patient is considered non-reliant if he or she has some medical expenses paid by a non-VA health insurance source. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level.

5.4.7 Health Care Needs of Recently Separated Veterans and VA Patients

The preceding analysis indicates that Veterans who become VA patients have greater rates of diagnosed disease prevalence than Veterans who do not use VA health care, even after controlling for key demographic characteristics. A combination of Veteran characteristics and VA policies may lead Veterans with greater health care needs or specific health conditions to use VA health care services at higher rates than healthier Veterans.

We explored the association of specific health conditions with VA use by comparing the prevalence of health conditions among recently separated Veterans, estimated with MHS encounter data, to the prevalence of the same health conditions among VA patients, estimated with VA encounter data. We assumed that nearly all health care for active military is provided by MHS and, thus, health condition prevalence estimates based on MHS encounter data reflect the true prevalence of diagnosed health conditions in this population. We used these estimates as a benchmark to determine whether some health conditions are over- or underrepresented in VA encounters. We did not have the permissions necessary to match MHS encounter data to VA encounter data at the individual level; therefore, we compared national prevalence rates (or rates in comparable large demographic groups). To match samples from MHS and VA as closely as possible, we focused on Veterans under age 35. We further restricted the MHS sample to Veterans who separated from service in 2012 or 2013. Separation dates and VA enrollment dates are not available in the VA encounter data. A limitation of this approach is that the prevalence of age-related chronic conditions is very low for this age group, so it is difficult to discern whether Veterans with these conditions disproportionately choose to use VA health care.

Figure 5-18 shows the unadjusted prevalence of health conditions estimated separately using MHS and VA encounter data. We report results on health conditions for which there are differences in prevalence rates between MHS and VA patients and on common chronic conditions with non-zero prevalence estimates. A table with the full set of conditions is available in Appendix C.2.

Figure 5-18. Health Condition Prevalence in MHS and VA Encounter Data for Young Veterans


SOURCE: RAND analysis of MHS encounter data (2012–2013) and VA encounter data (2014).
NOTES: Sample size, separating military personnel aged less than 35 in MHS = 325,849, and sample size, VA patients in the VA encounter data aged less than 35 = 503,205. Mental Health includes any mental health condition. Musculoskeletal conditions are those associated with chronic pain.

The results suggest that young Veterans' use of VA may be affected by health status. Specifically, although the prevalence of diagnosed mental health conditions overall is slightly higher among VA patients than newly separated Veterans, the prevalence of diagnosed PTSD among VA patients in particular is disproportionately larger among VA patients than among the full population of service members separating from DoD. This finding is consistent with differences in PTSD prevalence by VA patient status in the MEPS analysis. This may in part reflect disincentives for active duty military personnel to seek mental health services, including stigma and fear of negative career repercussions. Veterans with musculoskeletal conditions appear to be underrepresented in the VA patient population. However, some musculoskeletal conditions are not permanent or require less treatment over time, which could explain the difference in prevalence rates. Given the data limitations, it is not clear whether these differences are driven by individual choice or VA policy, or whether diagnosis of some conditions is more likely in particular health care systems.

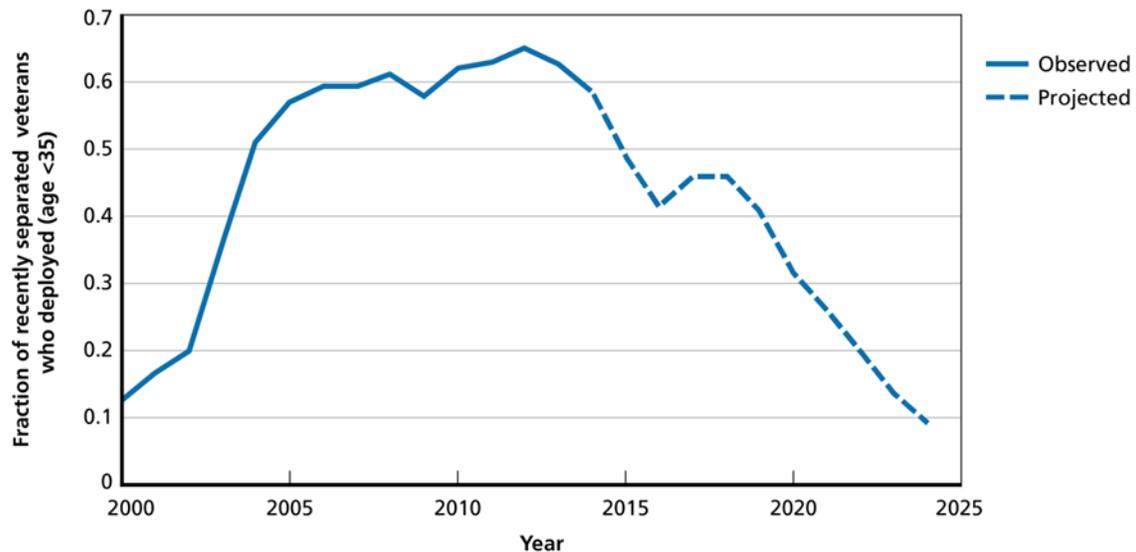
5.5 Future Health Care Needs of Veterans

5.5.1 Factors Driving Veteran Health Care Needs

Changes in the demographic composition of the Veteran population are likely to play a prominent role in determining future health care needs. For example, the prevalence rate of many chronic health conditions, such as diabetes, IHD, and many types of cancer, increases with age (Figures 5-6 and 5-15), and we predict that the average age of Veterans will increase over the next 10 years, especially for women (Figure 3-6). The number of female Veterans is also predicted to increase (Section 3), which could cause an increase in the overall prevalence of health conditions that disproportionately affect women. However, the number of female Veterans as a proportion of the total Veteran population will remain small, suggesting that this change in demographic composition is not likely to cause major shifts in Veterans' health conditions over the next 10 years.

Another plausible predictor of Veterans' future health conditions is their experience while in active military service. In particular, deployment and exposure to combat may increase the risk of injury and chronic health conditions and exacerbate existing conditions, although the evidence is mixed (Buckman et al., 2009; Kline et al., 2010; Hoge, Auchterlonie, & Milliken, 2006; Dobkin and Shabani, 2009). This is particularly important for considering demand for VA health services, because Veterans with service-connected disabilities are placed in a higher priority group for enrollment in VA than those without such conditions. The results in Section 5.3 indicate that the prevalence of mental health conditions, especially PTSD, is much higher among Veterans than among similar non-Veterans. The prevalence of these conditions is even higher among Veterans who use VA (Figure 5-12), making this an important factor to consider for future VA demand. Other conditions, such as TBI and musculoskeletal conditions, have also been tied to military service.

Deployment rates have been consistently high among recently separated Veterans, as seen in Figure 5-19. If the scope and intensity of U.S. military operations continue to decline, we expect fewer new Veterans in the future to have been deployed while on active duty. The projected separations under the assumption of no conflicts over the next 10 years show a steep decline in the fraction of new Veterans that deployed during service. As a result, we expect an associated decline in service-connected injuries and chronic health conditions among newly separated Veterans in the future. We also expect that those who deployed but did not separate from service soon after deployment and will be observed separating over the next 10 years are likely to have fewer health problems than those who did separate immediately, compounding this effect.

Figure 5-19. Fraction of Recently Separated Veterans Under Age 35 Who Deployed on Active Duty


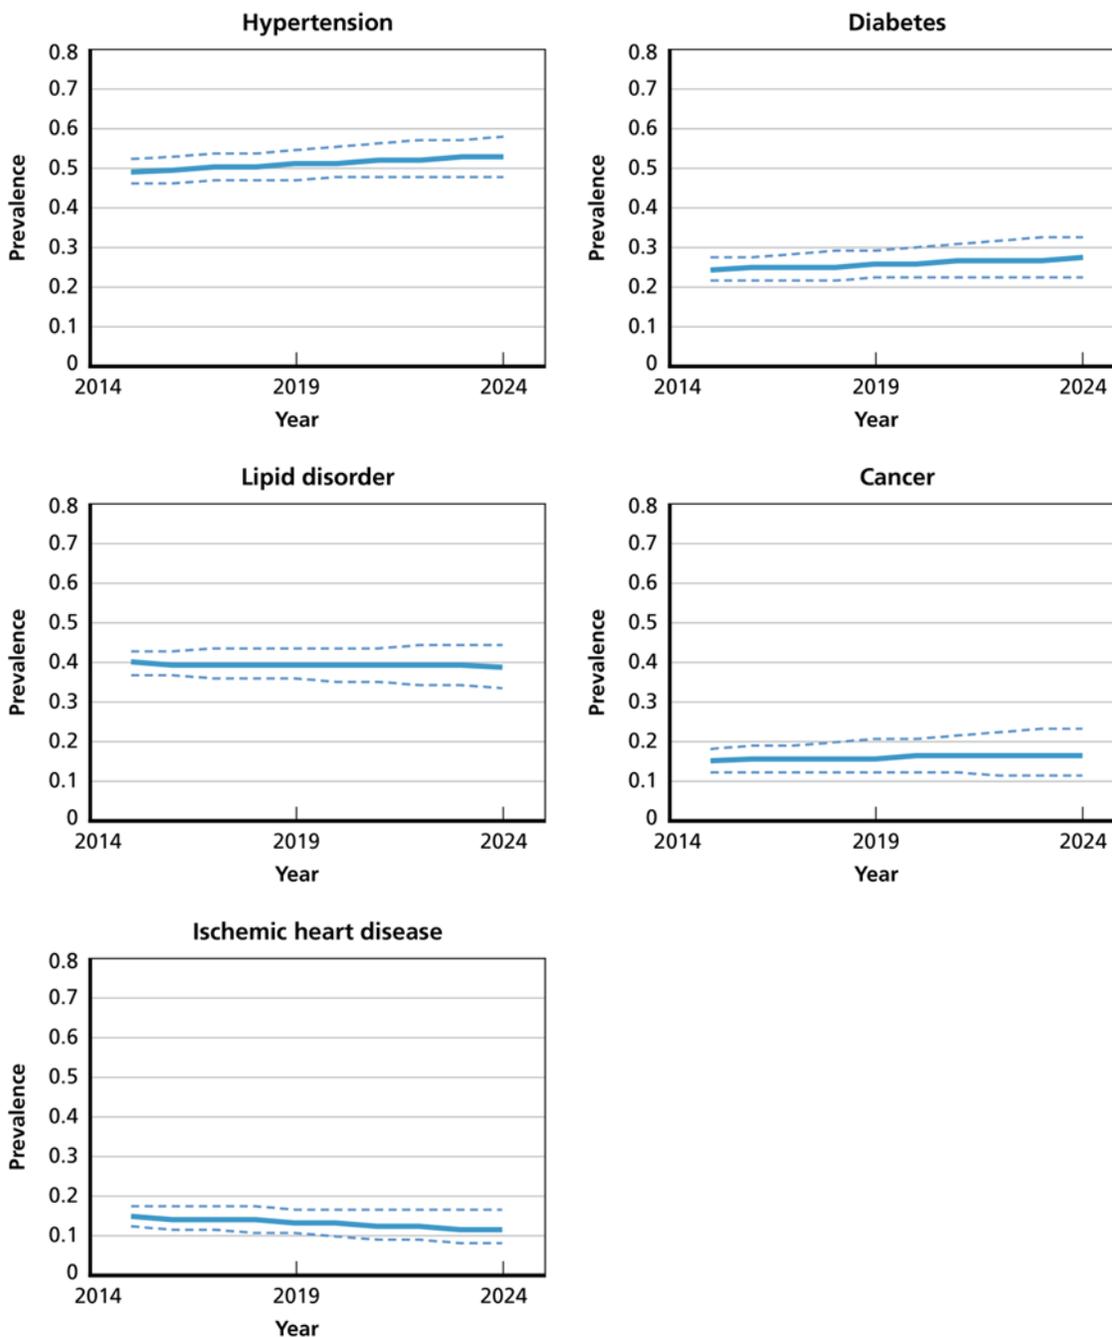
SOURCE: RAND analysis of DoD data.

5.5.2 Projected Health Care Needs of Veterans

The projections of health condition prevalence among Veterans incorporate a time trend of the prevalence of each health condition and account for changes in the demographic composition of the Veteran population. Because health conditions may be affected by service experience, the projections of conditions that are likely to have a substantial service connection—PTSD and mental health conditions, which include PTSD—are adjusted to account for this. This adjustment assumes that the prevalence of the condition remains constant within five-year birth cohorts rather than within five-year age bands and assumes a prevalence rate for future newly separated Veterans. For example, the prevalence of PTSD is higher among Veterans in their 60s than it is among Veterans just younger and older, probably because this cohort was more likely to have served in Vietnam. As a result, we do not expect that current 50-year-olds will suddenly have a higher prevalence of PTSD in 10 years when they turn 60. We used estimates of the health conditions of current military service members and among Veterans who have recently separated from service to inform the prevalence of health conditions among those who will separate from service and become Veterans during 2015–2024. The details of this empirical methodology are in Appendix C.1.5, and the sensitivity of the results to our assumptions is explored in Appendix C.4.3.

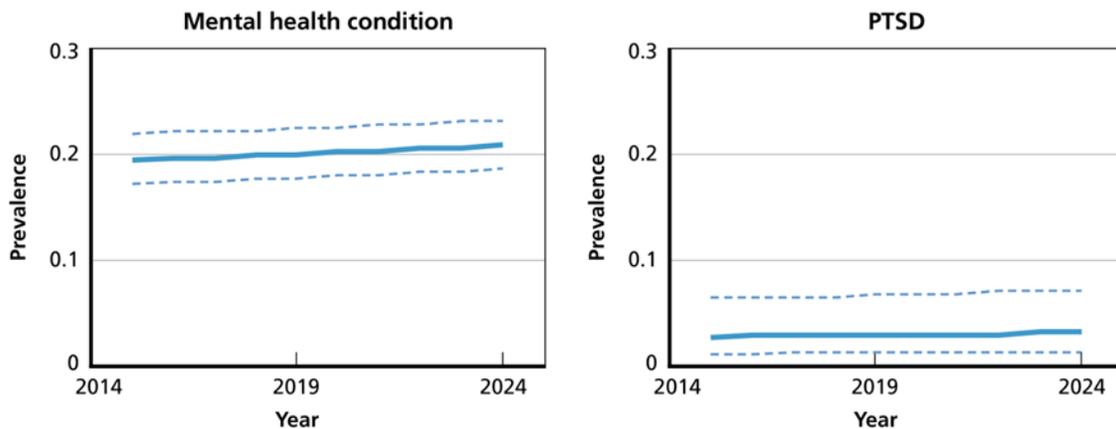
Figure 5-20 shows the projected trend in prevalence for selected health conditions among Veterans. The dashed lines around the projection line are conservative bounds (described in detail in Appendix C.1.5.6). Based on our projections, chronic health conditions that afflict both Veterans and non-Veterans are expected to increase moderately over the next 10 years. The projected increases in the prevalence of hypertension, diabetes, and cancer are centered around 10 percent, while the prevalence of lipid disorders remains relatively stable. Given that these conditions are more common among older adults, the projections are consistent with the

projected aging of the Veteran population over the next 10 years. However, while aging does tend to increase the prevalence of IHD, we estimated that prevalence rates for IHD will actually decline during 2015–2024. This finding is consistent with long-standing trends toward decreasing prevalence of acute coronary syndrome across all age groups in the U.S. population (Krumholz, Normand, & Wang, 2014; Talbott et al., 2013). However, this decline largely represents an extrapolation of recent declines in the prevalence of IHD noted in MEPS; this finding assumes that the previous trend toward reduced prevalence of IHD will continue. The relatively large confidence bands suggest that the trend is uncertain and actual prevalence may not decline as sharply (Appendix C.4.5).

Figure 5-20. Projected Prevalence of Selected Health Conditions Among Veterans (2015–2024)


SOURCE: RAND analysis of VA, DoD, Census, and MEPS data.
NOTES: MEPS sample size, Veterans = 12,313. Solid lines indicate the projected prevalence for each health condition, which accounts for the changes in the composition of the Veteran population by age, sex, race/ethnicity, Census region, and MSA. The dashed lines indicate conservative bounds for the projected prevalence rates. (See Appendix C.1.5 for methodological details.)

PTSD has been connected to military service experiences, particularly deployment-related combat exposure (Ramchand, Rudavsky, Grant, Tanielian, & Jaycox, 2015). Given that this condition is caused by specific trauma more generally, it is likely that this condition is predominantly determined by military experience rather than age among the Veteran population. We adjusted the projection of the prevalence of PTSD by linking estimated prevalence to birth cohorts rather than age, as discussed above. In order to make this adjustment, we assumed a prevalence rate of 5.4 percent for newly separated Veterans from 2015 to 2024. This prevalence rate, estimated using MHS data, is the average of the annual prevalence of PTSD among service members separating between 2009 and 2014. We also assume 35 percent of Veterans with PTSD remit in the first year post-service. The adjusted results are in Figure 5-21, and we project that the prevalence of PTSD will remain about the same from 2015 to 2024.[37]

Figure 5-21. Projected Prevalence of Service-Connected Conditions Among Veterans (2015–2024)


SOURCE: RAND analysis of VA, DoD, Census, and MEPS data.
NOTES: MEPS sample size, Veterans = 12,313. Solid lines indicate the projected prevalence for each health condition, which accounts for the changes in the composition of the Veteran population by age, sex, race/ethnicity, Census region, and MSA. The dashed lines indicate conservative bounds for the projected prevalence rates. (See Appendix C.1.5 for methodological details.)

PTSD is also included in the umbrella of any mental health condition, and for this population, PTSD is likely to have a strong effect on the prevalence of mental health conditions. Therefore, we also present adjusted results for the prevalence of any mental health condition in Figure 5-21. We used the same adjustment approach as for PTSD and assumed that the prevalence of any mental health condition among new Veterans will be 32.5 percent (also estimated with MHS). For mental health conditions, we assume a remission rate of 6.3 percent in the first year post-service, and zero thereafter. The remission rate is based on the fraction of Veterans with mental health conditions that have PTSD and the PTSD remission rate. With the adjustment, the prevalence of mental health conditions among Veterans is projected to

---

[37] Without the cohort adjustment, PTSD is projected to be 9.2 percent among Veterans in 2024, a 6-percentage-point increase.

increase to 20.7 percent by 2024. However, the umbrella of mental health conditions includes conditions that may not be related to service or that may have higher or lower remission rates than PTSD. If we treat mental health conditions like other predominantly age-related chronic conditions, such as hypertension, we project that the prevalence of mental health conditions among Veterans will be 26.1 percent by 2024. The details of these projection results are in Appendix C.4.3.

One particular limitation of our projections of health conditions relates to the timing of when a condition presents or when the individual seeks treatment from VA for the condition. For instance, if a Veteran experiences a hidden wound of war, such as PTSD or TBI, and either does not experience symptoms right away (e.g., delayed onset), does not enroll in VA and therefore does not receive treatment for some time after the injury, or does not file a claim for the condition soon after separating from the military, there may be a gap between injury or separation and when VA will treat the condition. Our projections are unable to account for this pattern. The data used to project health care needs (MEPS, MHS encounter, and VA encounter) lack information on when an injury occurred, when the Veteran separated from service, when the Veteran filed a disability claim, and when the Veteran enrolled in VA. Therefore, we are unable to determine if receipt of treatment for these hidden wounds of war occurred shortly after the injury or experience or if there was a delay. Using historical data on the time between separation and either when a disability claim was filed or when the condition was first treated by VA would allow for an adjustment to our projections that accounts for future cases of hidden wounds of war for which VA does not yet have visibility.

The projection results for the full set of conditions that could be estimated using MEPS are included in Appendix C.4. Many service-connected injuries and chronic conditions of interest have low prevalence in the general population and cannot be reliably estimated using MEPS, so they are excluded from the projections.

5.6 Future Health Care Needs of VA Patients

5.6.1 Factors Driving VA Patient Health Care Needs

VA patients are a subset of the Veteran population; thus, the same factors and trends that affect the health care needs of Veterans overall will also affect the needs of VA patients. To project VA patient health care needs, we used the same approach and the same set of assumptions that we used for the Veteran population.

In addition to the factors and trends that affect the health care needs of the Veteran population overall, the needs in the VA patient population are determined in part by who uses VA health care services. Changes in VA policies—such as new priority group cutoffs for enrollment eligibility, additions of new presumptive service-connected conditions, or changes to the enhanced eligibility benefits for new combat Veterans—will directly affect the number and composition of Veterans who are eligible to receive VA health care services. External factors that affect access to affordable health care, such as fluctuations in the economic climate or changes in the eligibility rules for other public health programs (e.g., Medicare) have the potential to affect VA use rates and the composition of the VA patient population. We assumed

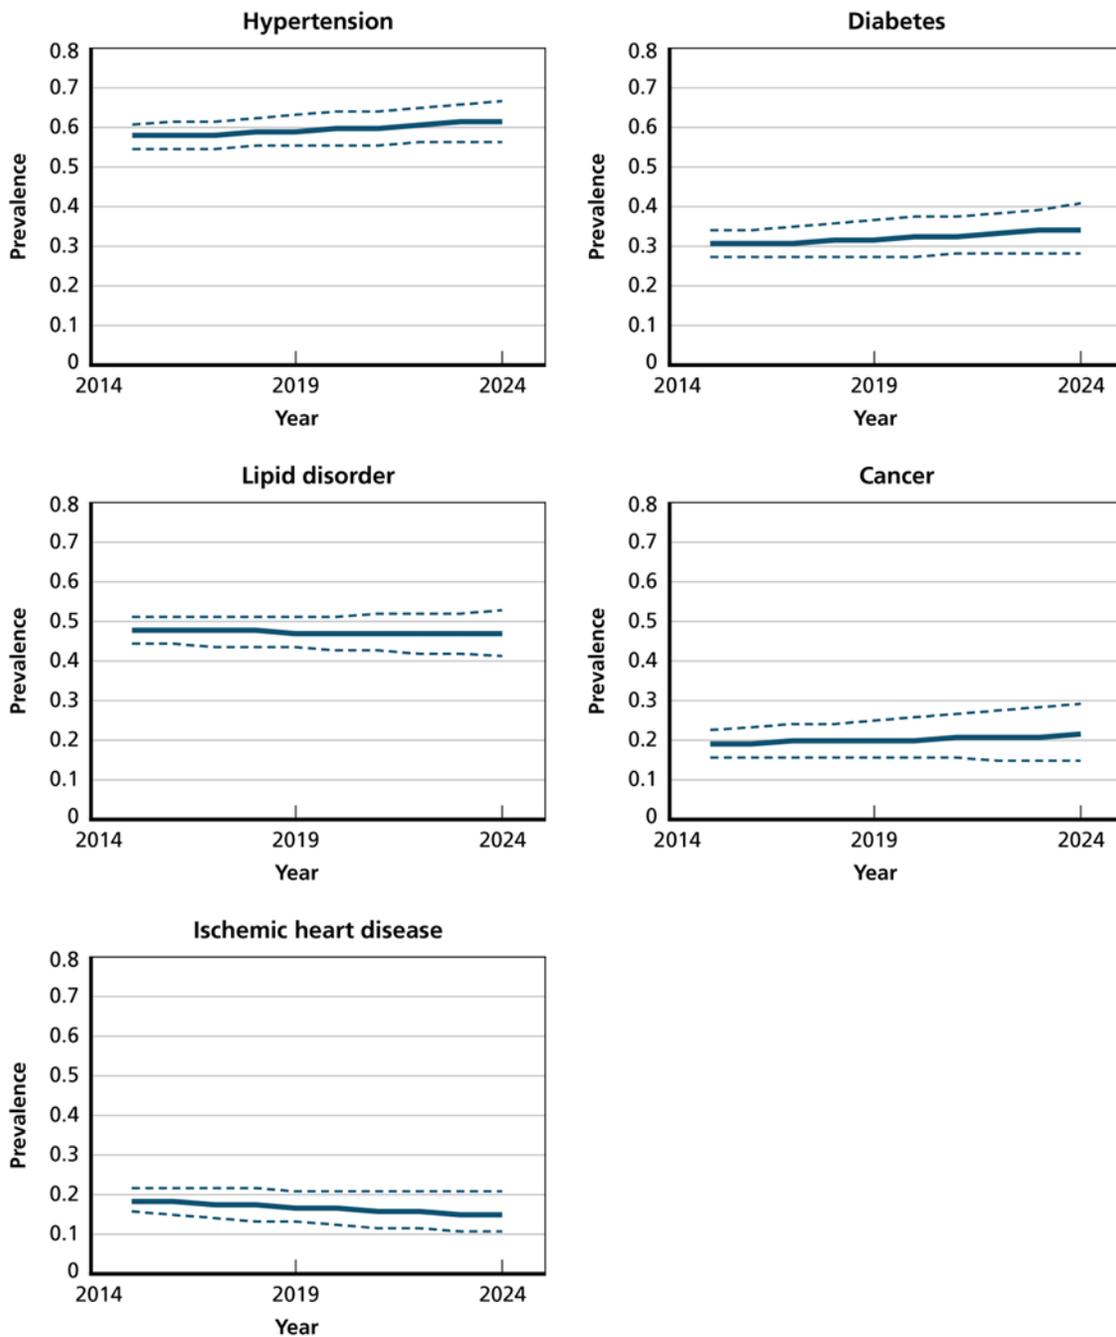
that these factors remain constant over the next 10 years in these baseline projections. The effects of policy changes on future Veteran, enrollee, and patient counts are considered in the scenario analyses in Section 6.

5.6.2 Projected Health Care Needs of VA Patients

We projected the health care needs of VA patients using MEPS and VA encounter data (data sources are detailed in Section 2.6). MEPS was used to estimate and project prevalence of more-common chronic conditions based on receipt of care from any provider. We used VA encounter data to estimate and project demand for VA health care services and to estimate and project the prevalence of predominantly service-connected conditions, which cannot be reliably estimated using MEPS because of their low prevalence.

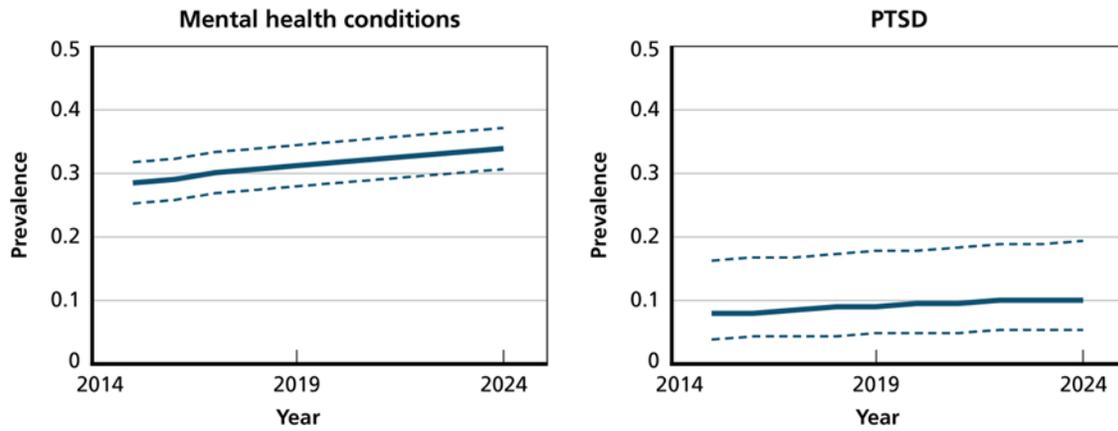
Figure 5-22 shows projected VA patient health care needs. The prevalence rates of hypertension and diabetes are projected to increase, and the prevalence rates of lipid disorders and cancer are projected to remain constant. As for Veterans overall, the prevalence of IHD is projected to decline among VA patient (see Appendix C.4.5 for further discussion).

As noted, the prevalence of PTSD, which is also a component of mental health conditions, is more likely linked to military experience than age. We adjusted the projections of mental health conditions and PTSD among VA patients using the same approach we used to adjust the projected prevalence of these conditions for all Veterans. However, we assumed a higher prevalence of mental health conditions and PTSD among newly separated Veterans *who become VA patients* than we did among newly separated Veterans overall. We assumed that the prevalence rates are 48.8 percent for any mental health condition and 17.3 percent for PTSD. These prevalence rates were derived from VA encounter data, MHS encounter data, and recently published work comparing prevalence rates between Veterans who use VA health care services and those who do not (Dursa, Reinhard, Barth, & Schneiderman, 2014). We also assume a PTSD remission rate of 30 percent in the first year post-VA enrollment and a mental health condition remission rate of 10 percent in the first year post-VA enrollment. The approach is detailed in Appendix C.1.5. Despite their magnitude, the prevalence rates for newly separated Veterans who become VA patients will not have a large effect on the overall prevalence rates for the VA patient population, because new patients are a small portion of the total VA patient population.

Figure 5-22. Projected Prevalence of Selected Health Conditions Among VA Patients (2015–2024)


SOURCE: RAND analysis of VA, DoD, Census, and MEPS data.
NOTES: MEPS sample size, VA patients = 4,871. Solid lines indicate the projected prevalence for each health condition, which accounts for the changes in the composition of the VA patient populations by age, sex, race/ethnicity, Census region, and MSA. The dashed lines indicate conservative bounds for the projected prevalence rates. (See Appendix C.1.5 for methodological details.)

The projected prevalence rates of mental health conditions and PTSD among VA patients are presented in Figure 5-23. The overall prevalence of any mental health condition among VA patients is projected to be 33 percent by 2024, and the prevalence of PTSD is projected to increase to be just over 10 percent in 2024. As with all Veterans, mental health conditions are not purely service-connected. If we treat mental health conditions like other predominantly age-related chronic conditions, such as hypertension, we project that the prevalence of mental health conditions among VA patients will be about 37 percent by 2024. The details of these projection results are in Appendix C.4.

Figure 5-23. Projected Prevalence of Service-Connected Conditions of VA Patients (2015–2024)


SOURCE: RAND analysis of VA, DoD, Census, and MEPS data.
NOTES: MEPS sample size, VA patients = 4,871. Solid lines indicate the projected prevalence for each health condition, which accounts for the changes in the composition of the VA patient populations by age, sex, race/ethnicity, Census region, and MSA. The dashed lines indicate conservative bounds for the projected prevalence rates. (See Appendix C.1.5 for methodological details.)

We used VA encounter data to estimate the prevalence of two conditions of particular interest to VA: TBI and musculoskeletal conditions. VA encounter data were used to estimate the prevalence of *VA-diagnosed/treated* health conditions among VA patients.[38] MEPS prevalence estimates include diagnoses made by VA and non-VA providers, and because many VA patients use non-VA providers for some health care services, MEPS provides a more comprehensive estimate of diagnosed prevalence rates among VA patients. However, the VA encounter estimates provide a better picture of the condition-based demand for VA health care services.

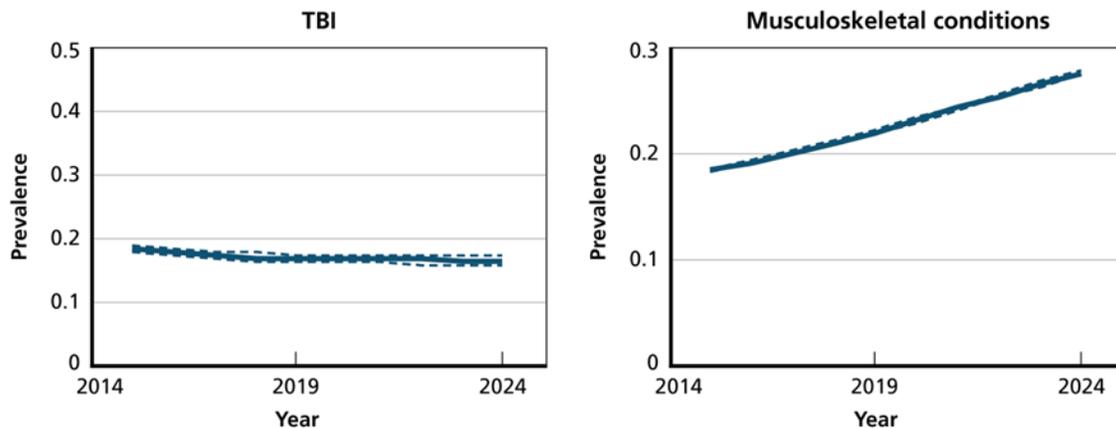
Our projections are presented in Figure 5-24. We project increases in the number of VA patients with both conditions. The prevalence of TBI, like PTSD and mental health conditions, is more likely linked to military experience than age. We used the same approach to adjust the projected prevalence of TBI. The projected trend in the prevalence of musculoskeletal conditions reflects historical trends in the prevalence of these conditions, as measured with VA

---

[38] Additionally, the prevalence of TBI is too low to be reliably estimated with MEPS.

encounter data and projected changes to the age and sex composition of the VA patient population. The fit of the model is discussed in Appendix C.5.

It is important to note that the trends may be partially driven by increases in VA use for these conditions, rather than trends in true diagnosed prevalence. In addition, the rates of diagnosis of these conditions may have increased due to heightened awareness and improved understanding of these conditions. We are not able to disentangle these effects.

Figure 5-24. VA Encounter-Based Projections of Health Conditions Among VA Patients (2015–2024)


SOURCE: RAND analysis of VA, DoD, Census, and MEPS data.
NOTES: VA encounter sample size, VA patients = 5,871,766. Solid lines indicate the projected prevalence for each health condition, which accounts for the changes in the composition of the VA patient populations by age, sex, race/ethnicity, Census region, and MSA. The dashed lines indicate conservative bounds for the projected prevalence rates. (See Appendix C.1.5 for methodological details.) Musculoskeletal conditions are those associated with chronic pain.

5.7 Summary of Key Findings

Veterans have a higher prevalence of many chronic physical health conditions than non-Veterans, in part because they are older. The prevalence of many chronic conditions, including cancer, diabetes, and GERD, is higher among Veterans than non-Veterans. This difference diminishes after adjusting for the differences in the demographic composition (particularly, age and sex) of the Veteran and non-Veteran populations. The remaining differences are small for most physical health conditions, including the prevalence rates of hypertension, heart disease, and lipid disorders, which are nearly identical across the two populations.

Veterans have a higher prevalence of mental health conditions than demographically matched non-Veterans. In contrast to the physical health conditions, the relative mental health status of Veterans worsens when they are compared with demographically matched non-Veterans. PTSD stands out as an important unique health need; the prevalence among Veterans is 13.5 times that of non-Veterans.

VA patients have a higher prevalence of chronic health conditions than Veterans who do not use VA health care services. Among Veterans, the prevalence rates (adjusted for demographic differences) of most chronic conditions we examined, including cancer, heart-related conditions, diabetes, and hypertension, are higher for VA patients than for Veterans who do not use VA health care services. This is at least partially the result of VA prioritizing enrollment by Veterans with higher prevalence of chronic health conditions (including those with service-connected conditions, disabilities, and lower incomes). The prevalence of any mental health condition among VA patients is nearly twice the prevalence among non-VA patients, and the prevalence of PTSD is 17.4 times larger. PTSD is associated with combat experience, which is an important predictor of Veterans' use of VA health care services.

The prevalence of diabetes, hypertension, and cancer among Veterans is projected to increase moderately over the next 10 years. For Veterans, we project moderate increases in the prevalence of diabetes (3 percentage points) and hypertension (4 percentage points), but a moderate decline in the prevalence of IHD (3 percentage points). These projections follow the recent trends in these conditions among the U.S. population.

The prevalence of mental health conditions among Veterans and VA patients is projected to increase. The prevalence of any mental health conditions and PTSD among Veterans is projected to increase by about 0.5 percentage points. Among VA patients, the prevalence of mental health conditions is projected to increase by 5.3 percentage points, while the prevalence of PTSD will increase by approximately by 2.4 percentage points. The expected declines in deployment and combat exposure among the newest Veterans and VA patients over the next 10 years will contribute to a slowing of the rate of increase of mental health conditions and somewhat smaller increases for PTSD in particular.

The gap in the prevalence of many health conditions between VA patients and Veterans who do not use VA health care services is projected to widen over the next 10 years. The projected increases in the prevalence of mental health conditions and PTSD among VA patients is larger than that among all Veterans, as cited above. The prevalence of diabetes, GERD, and cancer are also projected to increase more among VA patients than all Veterans, while the prevalence of other chronic conditions are projected to change by the same amount for the two populations.

6 Scenario Development and Evaluation

6.1 Introduction

Estimates of changes in populations and health care needs over time rely on a set of assumptions about how the policy environment and world will change over time. The demographic projections in this report are driven by historical information on military separation, Veteran mortality, and migration. For the health care needs analyses in Section 5, we inferred the future prevalence of health conditions from historical prevalence rates. These analyses assume that the future will resemble the recent past in many important dimensions, including the general size and function of the armed forces, migration patterns, the health care options and coverage available to Veterans, and the mission and function of VA in terms of health care delivery.

What if these dimensions change? The purpose of this section is to describe how changes to the status quo could affect Veteran, enrollee, and patient populations, and more broadly influence demand for VA care. To do this, we analyzed a range of policy scenarios. Policy scenarios are a tool that can help decision-makers understand the effects of "what ifs" as they plan for the future, especially when considered in conjunction with robust, validated baseline projections. We first identified a set of plausible scenarios, as described below, and then used modeling techniques to estimate the effect of each scenario on the size of the future VA patient population. As part of our evaluation of each scenario, we assessed how the scenario and impacts could be integrated into current VA modeling efforts, and, if it would not be possible to incorporate these changes into existing models, we propose a range of policy or modeling options to integrate and mitigate scenario impacts as appropriate.

Despite the usefulness of policy scenarios, there are two important caveats that apply to this section. First, each individual scenario is speculative and is based on assumptions that may diverge from actual conditions in the future. Second, due to time and data constraints, we were able to describe and evaluate only a limited set of policy scenarios. We chose these scenarios to be illustrative of important "what ifs" that VA could face in the future. However, specific details, such as the nature of a potential future conflict, cannot be reliably predicted.

6.2 Scenario Methodology Overview

Overview of Scenario Analysis Data and Methods

- To select scenarios for analysis, we generated candidate scenarios by reviewing scenarios that had been previously explored in VA analyses, conducting a targeted literature review, and consulting with other assessment teams and RAND subject-matter experts.
- We categorized scenarios by whether they would result in a change in (1) the population of eligible or enrolled Veterans or (2) the proportion of enrollees who use VA health care services.
- We selected analysis scenarios that were most likely to have substantive impacts on the size of Veteran or patient populations or Veterans' health care needs. These are:
  - Changes to VA eligibility by priority group
  - Changes in presumptive VA eligibility
  - Impact of future conflict on VA use
  - Improving access to VA Care
  - The ACA's coverage expansion.
- We used scenario-specific methods to develop and evaluate each scenario.
- These scenario-specific methods are described below and in more detail in Appendix D.

The research described in this section reflects two methodological steps. First, we developed five specific scenarios. Next, we developed scenario-specific evaluation methodologies to estimate the impact of each scenario on populations and demand for VA health care. The scenario-specific methodologies are described in detail in the following subsections and in Appendix D. The last subsection in this section discusses key results and conclusions from our scenario analyses. See Section 2 for a summary of VA's current use of scenarios in modeling and planning processes, focusing in particular on EHCPM.

This paragraph describes our methodology for choosing and defining specific scenarios for analysis. As a first step, we generated a list of candidate scenarios by reviewing scenarios that had been previously explored in VA analyses,[39] conducting a targeted literature review, and consulting with other assessment teams and RAND subject-matter experts. Candidate scenarios involved either a change in VA policy, a change in policy elsewhere in the government, or an external trend. We explored candidate scenarios that would have plausible impact on either the size of Veteran and patient populations or Veterans' health care needs. Through this process, we identified 12 candidate scenarios. Next, we developed a framework to help organize and guide our selection of five scenarios for analysis. The framework is described below. We selected for analysis those scenarios that were most likely to have substantive impacts on the size of Veteran or patient populations or Veterans' health care needs. Some of the candidate scenarios that were not selected for inclusion are discussed at the end of this section.

---

[39] The VA EHCPM analysts and the VA OACT have conducted scenario analysis; we reviewed documentation on these analyses and notes from our meetings with these offices.

6.3 Scenario Typology and Framework

We first categorized scenarios by whether they would result primarily in a change in (1) the population of eligible or enrolled Veterans or (2) the proportion of enrollees that are VA patients (i.e., that use VA health care services). These potential changes align with the analyses presented earlier in this report, including projections of the demographics of the Veteran population (Section 3) and projections of VA health care enrollees and patients (Section 4).

The primary outcome for all scenarios was the estimated *change in the number of VA patients by calendar year*. Following the framework laid out in Section 2, the number of VA patients is the product of the number of eligible Veterans, the enrollment rate, and the use rate, or, with the y subscript denoting year:

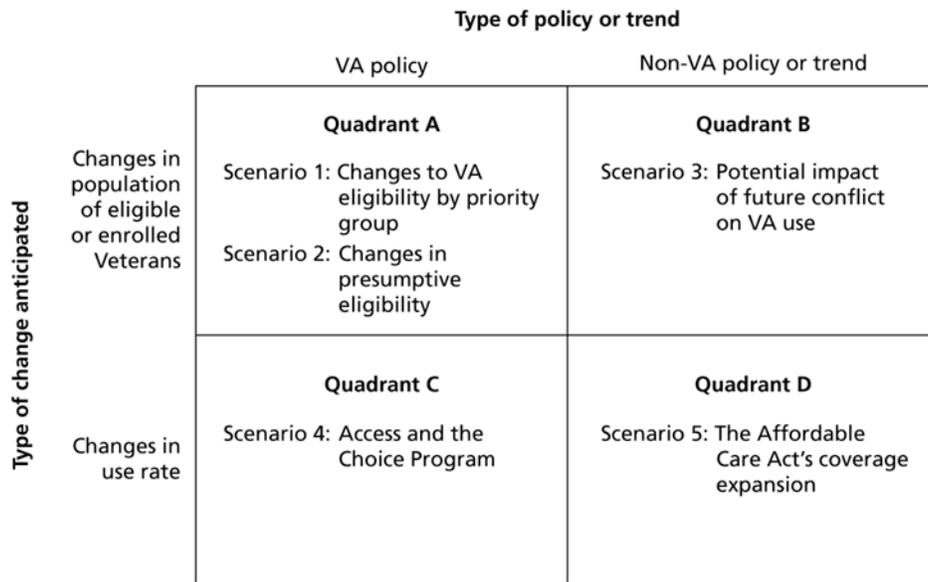
$$Patients_y = Eligible\ Veterans_y * Enrollment\ Rate_y * Use\ rate_y$$

Changes in the Veteran population—either in the number of Veterans or shifts in the composition of the Veteran population—can have important implications for the demand for VA health care. Even if the number of Veterans remains constant, shifts in the age, sex, priority group, or health status of Veterans can change demand for VA services to the extent that Veteran subpopulations utilize VA services differently.

Changes that directly affect how many VA enrollees choose to be VA patients would also influence the number of VA patients. As described in Section 4, demographic and other characteristics of Veterans, including whether Veterans have access to other sources of health coverage, are significant predictors of whether they use VA health care.

We also categorized scenarios into one of two types of policies or trends: (1) VA policies or legislation focusing on VA, or (2) broader policy changes outside of VA's control and external trends. We differentiated between these two policy or trend types to help describe whether VA has direct, indirect, or no control over the scenario.

The five specific scenarios are listed in Figure 6-1, a two-by-two framework incorporating the scenario types and change types introduced above. As shown in Quadrant A, we selected two scenarios that would change Veteran eligibility for health benefits. Other VA-focused policies or trends that directly influence the number of Veterans eligible for health benefits would likely share many characteristics and aspects of these two scenarios. As shown in Quadrant B, the hypothetical future conflict scenario describes how an influx of service members in response to a new conflict could translate into a flow of Veterans and ultimately VA patients. The future conflict analyses assess a range of plausible military manpower scenarios and their effect on projections of VA patients. In Quadrant C, the scenario analyzes policy options that could influence Veterans' decisions to use VA health care by changing actual or perceived access and quality of care in the VA system. Finally, the ACA coverage expansion scenario in Quadrant D describes the potential impacts of major shifts in the non-VA coverage available to Veterans on their decision to use or not use VA care. A range of other policies external to VA—such as changes in state Medicaid policy and the generosity and cost of employer-sponsored insurance—share characteristics with this fifth scenario.

Figure 6-1. Assessment A Scenario Framework


The following sections describe each scenario in more detail. We included contextual factors and details that could be important in determining the impact of these scenarios on demand for VA health care.

6.4 Changes to VA Eligibility, by Priority Group

6.4.1 Description

Under current VA policy, Veterans in priority groups 8e and 8g are not eligible to enroll for VA health care services. These Veterans satisfy the length-of-service requirement and the discharge criteria but do not have a service-connected disability rating, do not have a disability rendering them housebound, and do not qualify for Medicaid, and they have household income exceeding 110 percent of their GMT income limit. We modeled changes to VA eligibility by priority group by estimating the effects of a change in which these lower priority groups gained eligibility for health care services. In the first subscenario, we examined how many Veterans would become eligible for services if eligibility was extended to priority group 8e and the expected number of VA patients that would result. Second, we further examined how many Veterans would become eligible for services if eligibility was extended to the next-lowest priority group, 8g, and estimated the expected number of VA patients that would result.

6.4.2 Approach

Data and Methods for Scenario One, Changes to VA Eligibility by Priority Group

- We sorted all Veterans eligible for priority group assignments into priority groups in order to both estimate the size of the 8e and 8g Veteran populations and to test use rates for each eligible priority group.
- We used the 2013 ACS Public Use Microdata Sample (PUMS), which contains self-reported information on service-connected disability rating, VA health service use, family and household income, family and household size, individual income from a variety of sources, area of residence and Medicaid use.
- We employed an algorithm that assigns a priority group to each Veteran contained in the 2013 ACS, based on available data and adjustment factors drawn from administrative records.

In order to sort all Veterans into priority groups, this analysis had two essential components:

1. The identification of all U.S. Veterans in a nationally representative data set. To do this, we used the 2013 ACS PUMS, or 2013 ACS, which contains self-reported information on service-connected disability rating, VA health service use, family and household income, family and household size, individual income from a variety of sources, area of residence, and Medicaid use. The 2013 ACS, with demographic adjustments from VA administrative records, identifies approximately 21.9 million Veterans in the United States, with slightly more than 6 million Veterans using VA health services.

2. A priority group classification algorithm that assigns a priority group to each Veteran contained in the 2013 ACS, based on the available data described above and several adjustment factors drawn from administrative records (see Appendix D.1 for a thorough description of this algorithm).

Testing subscenarios in which eligibility for VA health services is expanded to new priority groups amounts to taking the algorithm's estimates of these ineligible priority groups and applying a use rate, estimated from the most similar eligible priority group, to arrive at an estimate of new VA patients.

Table 6-1 shows the baseline ACS estimates of Veterans *using* VA health services—that is, VA patients, by priority group, in comparison with VA administrative records of this population, along with a brief description of each priority group's eligibility requirements (for a thorough description of the eligibility requirements for each priority group, see U.S. Department of Veterans Affairs, 2015c). This comparison provides a validity test: The ACS estimates of VA patients should match administrative records. Indeed, these baseline ACS estimates are very close to the administrative records, with much of the deviation attributable to sampling error and comparisons across two distinct years.

However, the advantage of this approach is not in replicating administrative records, but in estimating the number of potentially eligible Veterans by priority group in the general Veteran population, a task for which administrative records are ill-suited. Although the administrative

---

data have records of Veterans in these priority groups who are eligible to use VA health services (e.g., 8e Veterans who are eligible for services for their 0-percent service-connected disability care), there are otherwise no estimates of the size or composition of this 8e and 8g population.

Table 6-1. VA Patients According to 2014 VA Administrative Data and 2013 ACS Estimates, by Priority Group

Priority Group	VA Patients, 2014	VA Patients in ACS, 2013
1 – Service Connected 50% +	1,599,076	1,641,000
2 – Service Connected 30% - 40%	489,192	502,000
3 – Service Connected 20%/POW/Special	741,713	761,000
4 – AA/Housebound or Catastrophic	191,342	117,000
5 – Non-Service Connected Below Income	1,315,317	1,350,000
6 – All Other Not Required to Make Co-Pay	276,275	304,000
7 – Non-Compensable Non-Service Connected Below GMT	174,810	192,000
8a, 8b, 8c, 8d – Non-Compensable Non-Service Connected Below GMT + 10%, or previously VA eligible	1,055,685	1,124,000
8e, 8g – Users	26,115	32,000
Priority Group Not Assigned	2,241	
Total	**5,871,766**	**6,022,000**

SOURCE: RAND calculations using 2013 ACS PUMS.

We tested two subscenarios for Scenario 1. The first estimated the number of new VA patients under the condition that Veterans in priority group 8e were eligible for these services; they currently are not eligible. The 8e subscenario uses the estimates of the number of Veterans classified as 8e and average priority group 8 use rates to estimate how extending eligibility to 8e would affect the number of eligible Veterans and the number of expected VA patients. Veterans in priority group 8g are also currently ineligible for VA health care services, so the 8e and 8g subscenario estimates the effects of expanding enrollment eligibility to both these priority groups.

6.4.3 Results

Table 6-2 shows estimates of all 21.9 million Veterans in the 2013 ACS by priority group[40], compared with the corresponding number of ACS-estimated VA patients by priority group. These two numbers allow us to calculate priority group–specific use rates, which are the ratios of VA patients to eligible Veterans in each priority group.

---

[40] In Section 3, we report that there are 21.6 million Veterans. This estimate was calculated using the 2014 ACS, whereas the 21.9 million reported here uses the 2013 ACS.

When the subscenarios below result in shifts in the number of eligible Veterans by priority group, these use rates will then translate the change in eligible Veterans into a change in expected VA patients in that priority group.

Table 6-2. 2013 ACS Estimates and Use Rates, by Priority Group and Eligibility Status

Priority Group and Eligibility Status	All Veterans in ACS, 2013	VA Patients in ACS, 2013	Average Use Rate in ACS (Patients/Eligible)
1	1,961,000	1,641,000	0.84
2	745,000	502,000	0.67
3	1,310,000	761,000	0.58
4	377,000	117,000	0.31
5	4,151,000	1,350,000	0.33
6	1,073,000	304,000	0.28
7	749,000	192,000	0.26
8a, 8b, 8c, 8d	2,572,000	1,124,000	0.44
8e, 8g users	32,000	32,000	1.00
8e nonusers	78,000		
8g nonusers	4,727,000		
Ineligible due to discharge status	1,246,000		
Ineligible due to length of service	2,903,000		
Total eligible for services	12,970,000		
Total eligible to apply for enrollment[a]	17,775,000		
Total Veterans	21,924,000	6,022,000	

SOURCE: RAND calculations using 2013 ACS PUMS.

[a] Not all Veterans who are eligible to apply for VA health care services are eligible to enroll and receive VA health care services under current policy.

Priority group 8e subscenario. Table 6-2 shows that there are 78,000 Veterans who, whether enrolled or not, would be categorized into priority group 8e if they applied for VA health care benefits. Thus, if eligibility to enroll in VA health care were extended to priority group 8e, there would be 78,000 newly eligible Veterans. Given that Veterans in priority group 8 overall have an average use rate of 0.44, there would be an expected 34,000 new VA patients as a result (78,000 × 0.44), increasing the overall number of VA patients by 0.6 percent. [41]

---

[41]It is possible that higher income Veterans who are not currently eligible to enroll would have lower use rates than Veterans currently enrolled in priority group 8. If this were the case, we may overestimate that number of Veterans that would be likely to use care if the VA expanded eligibility to all Veterans in priority group 8.

Priority group 8e and 8g subscenario. Table 6-2 shows that there are 4,727,000 Veterans who would be categorized into priority group 8g if they applied for VA health care benefits.[42] Thus, when combined with the 78,000 Veterans in 8e, there would be 4,805,000 newly eligible Veterans if eligibility to enroll in VA health care were extended to both 8e and 8g. As above, given the average priority group 8 use rate of 0.44, there would be an expected 2,114,000 new 8e and 8g VA patients as a result (4,805,000 × 0.44), an increase of 35.1 percent over the current VA patient population.

6.4.4 Discussion

We estimate that expanding enrollment eligibility for VA health care to include priority group 8e would bring in a modest number of new Veteran users, increasing the number of patients by 0.6 percent. However, we estimate that there are a substantial number of Veterans in priority group 8g. An expansion to include this group would markedly increase the current number of eligible Veterans and users. Expanding eligibility to enroll in VA health care to include both groups of Veterans (priority groups 8e and 8g) would bring in a large number of new Veteran users, increasing the number of patients by 35.1 percent. However, such an estimate is based on current priority group 8 use rates, and this estimate may be different if the population of Veterans in this priority group changes.

The subscenarios tested here correspond to expansions of eligibility or generosity of the VA program. We did not test any contractions in eligibility or generosity for two reasons. First, historically, such contractions have been accompanied by grandfathering in currently eligible Veterans, and because this analysis is static in its analysis of 2013 Veterans, these future dynamics are outside the scope of this analysis's capabilities. Second, such a contraction-based analysis does not require estimates of eligible Veterans, just current and projected enrollees and users, for which administrative records are well-suited. Nevertheless, our baseline counts of all eligible Veterans by priority group give estimates of the overall size of each of these priority groups, which may be useful for other scenario-based models.

---

[42] This estimate of the size of potential priority group 8g Veterans is determined by sorting Veterans into higher priority groups. The next step is to subtract those who do not satisfy length-of-service or discharge requirements from the remaining unsorted Veteran population. See Appendix D for a description of determining how many Veterans do not satisfy these criteria. However, it should be noted that the length-of-service and discharge requirements are treated independently and thus represent an overestimate of the ineligible Veteran population.

6.5 Changes in Presumptive Eligibility

6.5.1 Description

When a Veteran's military service has resulted in physical or mental impairment, that Veteran is granted such benefits as compensation and health care depending on the extent of impairment. However, not all impairments can be factually linked by evidence to military service. Since 1921, Congress has authorized VA to establish criteria for impairments that are likely (but unproven) to be service-connected. Since that time, more than 150 conditions have been categorized as service-connected. In the Agent Orange Act of 1991, Congress directed VA to periodically review the quality of the evidence for presuming service-connection for impairments experienced by Veterans (Samet & Bodurow, 2008). If VA finds that there has been a systematic impact on Veteran health, VA then revises its eligibility criteria. The revised eligibility standard typically specifies that when a Veteran served in a particular location during a particular time frame and has a particular condition—that condition is presumed to have been caused by military service and the Veteran is now eligible to enroll in VA health care.

VA contracts with IOM to review every two years the medical literature on Vietnam-era Veterans. Table 6-3 shows IOM's latest evidentiary findings for Vietnam Veterans for a variety of health conditions. In 2006, IOM moved hypertension from "Inadequate or Insufficient Evidence to Determine an Association" to "Limited or Suggestive Evidence of an Association." As of the writing of this report, VA had not added hypertension to the list of presumptive conditions for Veterans who served in Vietnam. This scenario examines the potential impact of adding hypertension to the list of conditions that would allow VA to presume that a Vietnam-era Veteran with hypertension is service-connected.

Table 6-3. IOM's Assessment of the Evidence Connecting Certain Health Conditions to Military Service in Vietnam

Sufficient Evidence of an Association
Soft-tissue sarcoma (including heart); non-Hodgkin lymphoma; chronic lymphocytic leukemia (including hairy cell leukemia and other chronic B-cell leukemias); Hodgkin lymphoma; chloracne
Limited or Suggestive Evidence of an Association
Laryngeal cancer; cancer of the lung, bronchus, or trachea; prostate cancer; multiple myeloma; AL amyloidosis (category change in 2006); early-onset peripheral neuropathy (category change in 2010); Parkinson disease (category change in 2006); porphyria cutanea tarda; hypertension (category change in 2006); ischemic heart disease (category change in 2008); stroke (category change in 2012); Type 2 diabetes (mellitus); spina bifida in offspring of exposed people
Inadequate or Insufficient Evidence to Determine an Association
Cancers of the oral cavity (including lips and tongue), pharynx (including tonsils), or nasal cavity (including ears and sinuses); cancers of the pleura, mediastinum, and other unspecified sites in the respiratory system and intrathoracic organs; esophageal cancer (category change in 2006); stomach cancer (category change in 2006); colorectal cancer (including small intestine and anus) (category change in 2006); hepatobiliary cancers (liver, gallbladder, and bile ducts); pancreatic cancer (category change in 2006); bone and joint cancer; melanoma; nonmelanoma skin cancer (basal-cell and squamous-cell); breast cancer; cancers of reproductive organs (cervix, uterus, ovary, testes, and penis; excluding prostate); urinary bladder cancer; renal cancer (kidney and renal pelvis); cancers of brain and nervous system (including eye); endocrine cancers (thyroid, thymus, and other endocrine organs); leukemia (other than chronic B-cell leukemias, including chronic lymphocytic leukemia and hairy cell leukemia); cancers at other and unspecified sites; infertility; spontaneous abortion (other than after paternal exposure to TCDD [tetrachlorodibenzodio], which appears not to be associated); neonatal or infant death and stillbirth in offspring of exposed people; low birth weight in offspring of exposed people; birth defects (other than spina bifida) in offspring of exposed people; childhood cancer (including acute myeloid leukemia) in offspring of exposed people; neurobehavioral disorders (cognitive and neuropsychiatric); neurodegenerative diseases, excluding Parkinson disease; chronic peripheral nervous system disorders; **hearing loss (added in 2010)**; respiratory disorders (wheeze or asthma, chronic obstructive pulmonary disease, and farmer's lung); gastrointestinal, metabolic, and digestive disorders (changes in hepatic enzymes, lipid abnormalities, and ulcers); immune system disorders (immune suppression, allergy, and autoimmunity); circulatory disorders (other than hypertension, ischemic heart disease, and stroke); endometriosis; disruption of thyroid homeostasis; **eye problems (added in 2010)**; **bone conditions (added in 2010)**
Limited or Suggestive Evidence of No Association
Spontaneous abortion after paternal exposure to TCDD [tetrachlorodibenzodio]

SOURCE: Institute of Medicine of the National Academies, 2013. Underlined modifications from earlier editions published in 2005, 2007, 2009, and 2011.
NOTES: Underlined: Category change in response to additional evidence. **Bold**: Additional conditions added to the conditions being monitored.

6.5.2 Approach

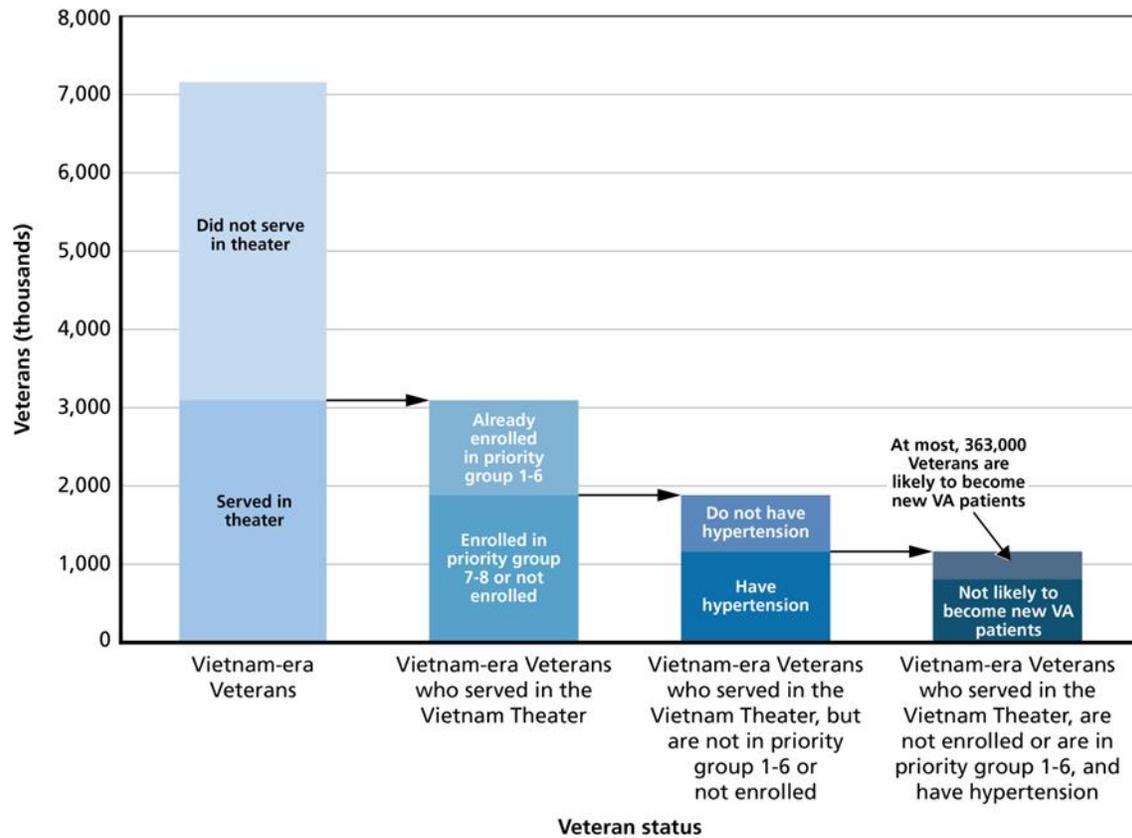
Data and Methods for Scenario Two, Changes in Presumptive Eligibility

- We used data from MEPS to estimate the maximum number of Veterans who would newly use VA health care if VA included hypertension presumptively as a service-connected condition for Veterans who served in Vietnam.
- We employed an algorithm that assigns a priority group to each Veteran contained in the 2013 ACS, based on available data and adjustment factors drawn from administrative records.

The purpose of this scenario was to estimate the maximum number of Veterans who would newly utilize VA health care if VA decided that hypertension could be presumptively included as a service-connected condition for Veterans who served in Vietnam. We relied on estimates from NSV for information about the number of Veterans who served in Vietnam. We used VA business intelligence data to determine the proportion of these Veterans who are currently VA patients (we use age as a proxy for service in the Vietnam era). For the prevalence of hypertension in Veterans and current VA patients, we relied on MEPS. (See Section 5 and Appendix C for more information.) We applied the ratios of service in theater and hypertension to the Veteran populations who were eligible to receive VA health care but were not enrolled in VA health care, or were enrolled in the higher priority groups (7 and 8). Our detailed methods are described in Appendix D.

6.5.3 Results

The progression from Vietnam-era Veteran to likely enrollee is illustrated in Figure 6-2. The total height of the first bar represents the 7 million living Veterans who served during the Vietnam era, and the blue portion represents the approximately 3 million who served in theater. Of the 3 million, 61 percent are not enrolled or are in priority group 7 or 8 (where care is not free) (second bar). Among those not enrolled (but eligible for enrollment with other-than-dishonorable discharges) or in priority group 7 or 8, we estimate that 65 percent have hypertension (third bar). This hypertension prevalence rate is an average of the prevalence rate for enrolled Veterans in priority groups 7 and 8 (70 percent) and the rate for the non-enrolled Vietnam-era Veterans (62 percent). The height of the fourth bar is equivalent to those who could enroll as a result of a presumptive service connection for hypertension. Of course, not all of those who are eligible will enroll, so we therefore estimate that of the non-enrollees who have hypertension, 31 percent are likely to enroll and become patients (approximately 363,000 new patients).

Figure 6-2. Progression from Vietnam-Era Veterans to Likely New VA Patients If Hypertension Is Adopted as a Presumptively Service-Connected Condition


SOURCE: RAND analysis of NSV, MEPS, ACS, and VA Business Intelligence (Enrollment) data.

6.5.4 Discussion

An increase of 363,000 new patients would represent an increase of 6.4 percent in VA's total patient population (5.7 million in 2014 as reported in EHCPM output). The key driver of our estimate is the use rate for Veterans with hypertension: While we calculated use rates for the relevant Veteran population in MEPS, actual enrollment and use rates by the newly eligible may be higher or lower than our assumptions.

6.6 Potential Impact of Future Military Conflict on VA Use

6.6.1 Description

The United States has spent roughly 25–35 percent of the past 115 years engaged in some form of armed conflict. If past experience is any guide, the chances of future conflict are high (Kavanagh, 2013). Conflict affects the size of the VA patient population in three significant ways. First, the authorized end-strength of the military may grow larger, which translates into larger cohorts of Veterans when those additional personnel eventually separate. Second, conflict may increase the number of service members who will qualify for VA health benefits, through a wide range of mechanisms, including activation of reserve/National Guard units, deployment into a theater of combat, increased risk of service-connected disability, and automatic placement into higher VA priority groups. Third, exposure to the conflict environment may carry unique health risks that are rare among the non-Veteran population. Consequently, Veterans with conflict-related health conditions are likely to rely on VA for a larger portion of their care. Taken together, this suggests that future conflict is both likely to occur and likely to affect the demand for VA health care.

In the future conflict scenario, we examined the potential consequences of future conflict on demand for VA health care over the next 10 years. These analyses are not models of war itself. Rather, they are models of how changes in both the size of the military and the average exposure to conflict among service members have consequences for the number of new patients using VA health care services. We examined 36 future conflict scenarios based on different assumptions about how end-strength would be affected, how widely service members would be exposed to conflict, and how rates of VA health care enrollment or reliance on VA for health care would vary. We then observed the commonalities across scenario assumptions— which patterns tended to hold, regardless of the specific assumptions made.

In projecting the implications of conflict for VA health care, we are not breaking new ground. VA, DoD, and Congressional Budget Office analysts are among those who have built models to examine this contingency. However, conflict consequences are difficult to model, and transparency on current modeling approaches is relatively scarce,[43] so there is significant room for contributions to this type of modeling. In addition, we examined how different combinations of assumptions interact to produce different consequences, which may aid future model consumers in understanding how models differ, and when those differences matter. We also built on previous RAND research on force planning and personnel patterns, which imbues our model with unique insights into service member separation choices and how these would be shaped by the near-term policy environment. This includes research into the poor performance of stop-loss (Brady, 2014), positive impact of deployment on retention rate (Hosek & Martorell, 2009), difficulties maintaining deployment readiness among reserve components (Brauner, Jackson, & Gayton, 2012; Pint et al., 2015), and the effectiveness of incentive-based retention strategies (Asch et al., 2010).

---

[43] Some of this is by necessity. Much of the defense modeling on this topic is understandably classified.

6.6.2 Approach

Data and Methods for Scenario Three, Impact of Future Conflict on Demand for VA Care

- We used data from DMDC and the U.S. Census Bureau, DoD planning documents, the NSV, and the SoE to examine 36 potential future conflicts and their impact on demand for VA health care between 2015 and 2024.
- We employed a conversion process that begins with a starting population (current Veterans in VA's model) and winnows this down to the segment that will eventually rely on VA for at least part of its health care. Our projections involved two conversions: how end-strengths of the U.S. military translate into separations from the military and how separations from the military translate into VA patients.

As in VA's own models, ours modeled a conversion process by which a starting population (service members in these projections; Veterans in VA's model) is winnowed down to just the segment that will eventually rely on VA health care for at least part of its care. Many of these conversions are difficult to predict (e.g., when the next war will break out, and how widespread exposure to the conflict environment will be), so we calculate conversion rates under different assumptions, and then examine the resulting range of outcomes. Our projections involved two conversions: (1) how the end-strength of the U.S. military translates into separations from the military, and (2) how separations from the military translate into VA patients. In our models, the first conversion and final projection figures were calibrated and validated against the VA population projections in Section 3. The second conversion was validated against the enrollment and reliance rates in Section 4.

Military end-strength scenarios. The total size of the U.S. military is difficult to forecast, because it can change rapidly to accommodate the current security needs of the United States. Therefore, we created six potential scenarios of end-strength for the 2015–2024 period. These projections included the active, reserve, and National Guard components of the Army, Navy, Air Force, and Marine Corps—about 2.2 million service members in 2014. Each scenario extrapolated from manpower statistics and planning documents.

Three scenarios ("build up") started from historical data (Defense Manpower Data Center, 2014; U.S. Census Bureau, 2012b) for the post-2000 period to estimate how high end-strength could rise. They projected the total end-strength that would result if each component of each service rose to its highest historical level for the post-2000 period, peaked, and then steadily declined afterward. This rise-peak-decline pattern is typical for a war-time surge. For the Army and Marine Corps, maximum end-strength occurred between 2009 and 2011, to better meet the challenges of the wars in Afghanistan and Iraq. For the Navy and Air Force, this occurred between 2002 and 2004, before a new wave of technological improvements allowed both services to reduce the quantity of personnel necessary to operate their respective fleets. While reduction from those levels was driven by technical change, it is conceivable that new roles and

---

technologies could lead to these staffing levels being re-attained in future conflicts. In fact, an air and sea war, perhaps fought over the Pacific, could exceed these force size projections.[44]

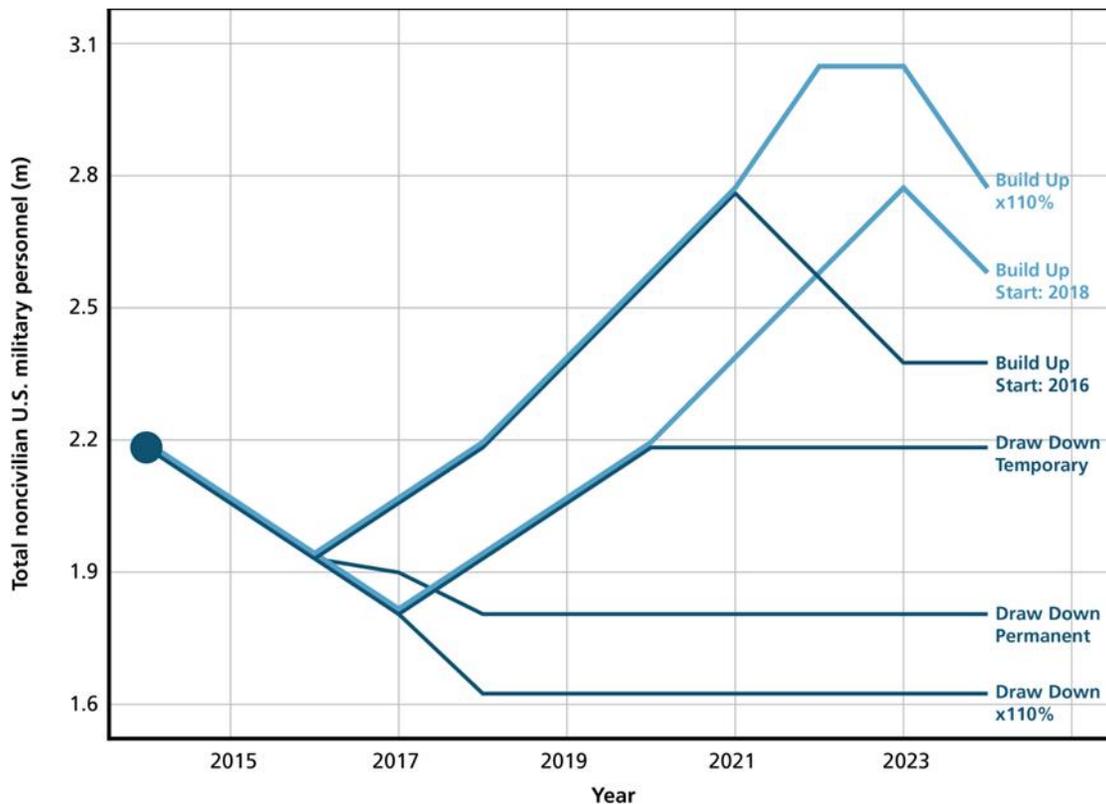
The other three end-strength scenarios ("draw down") estimated how low end-strength could fall. They follow a similar strategy as the "build-up" scenarios, but project the end strength that could result from the sequestration cuts scheduled to occur by 2019, as described in DoD planning documents (Office of the Under Secretary of Defense (Comptroller), 2015), the Quadrennial Defense Review (U.S. Department of Defense, 2014), and the Congressional Budgeting Office's analysis of them (Congressional Budget Office, 2014a). The planned cuts formed the backbone of these projections because, with few exceptions, they are lower than any historical force level in the 2000–2014 period. In the cases where they are not (active duty Marine Corps and Army Reserve/National Guard in 2000), we used historical lows instead of the sequestration cuts. Figure 6-3 reports the total end-strength for each scenario over time.[45] Appendix D reports all historical/planned maximums and minimums for each segment of the U.S. military.

For all scenarios, the drawdown to minimum or buildup to maximum was implemented over the course of three years. Given the minimum, maximum, and current end-strengths observed, this approximates the end-strength rate of change observed during the 2007–2010 surge.

---

[44] Because the United States has not fought an air and sea war since World War II (and that was fought concurrently with a large land war), there is not enough historical performance data to project an end-strength scenario.

[45] The equivalent 2024 figures for the active duty Army are as follows: 622,000 (increase × 110 percent), 566,000 (increase, starting 2016), 538,000 (ramp up, starting 2018), 510,000 (temporary decrease), 420,000 (permanent decrease), and 378,000 (decrease × 110 percent).

Figure 6-3. End-Strength Scenarios (total non-civilian U.S. military personnel)


SOURCE: RAND calculations based on DoD administrative data (2015), Census Bureau data (2012), Congressional Budget Office analysis (2014), and U.S. Army posture statements (2014).

Combat exposure scenarios. While end-strength could have consequences on the demand for VA care, the total size of the U.S. military is not necessarily related to how much combat exposure service members will receive. To capture those potential effects, we created three potential scenarios of possible combat exposure. Each scenario projected the total number of combat exposures that would result if each component of each service experienced the maximum, minimum, and average rate of hostile deployment that it witnessed between 2000 and 2014 for each year of the 2015–2024 period.[46] Appendix D reports all historical ranges for each segment of the U.S. military.

Separating service members. A great deal of research has examined service member separation patterns. This research suggests a complex relationship between personal expectations, life situation, deployment, and the chances of re-enlisting. While extended hostile deployments tend to decrease the chances of reenlistment, moderate deployments actually increase those chances (Hosek & Martorell, 2009). Moreover, the current system of targeted incentives has proven an effective tool for shaping these chances to meet current personnel

---

[46] In these scenarios, the combat exposure rates do not vary with surges in end-strength, because they do not correspond strongly in the historical data for the 2000–2014 period. While surges in end-strength may correspond with a more intense war effort, they also lower each service member's chance of being deployed.

---

needs (Asch et al., 2010). Consequently, rates of separation tend to reflect DoD personnel needs, much more than individual factors. Therefore, we modeled separation patterns from the perspective of DoD. Under average conditions, what rates of separation are typical among the various ranks, components, and services? When end-strength needs change, how are these cuts or increases typically realized among the various ranks, components, and services? We formulated a regression model to examine the relationship between total end-strength, changes in end-strength, and separation rates for each service, component, and officer/enlisted segment. This model contained 48 separate coefficients to characterize all of these features, and the interactions between them. However, the basic patterns they revealed can be summarized in just four points:

- Enlisted service members average less time on active service than officers before separating, and account for most of the extra separation changes when required end-strength declines. To be precise, DMDC separation records suggest that, in 2013, 75 percent of enlisted service members separated within eight years, while 75 percent of officers separated over the course of 16 years. Among active component service members, those figures were 11 years and 22 years, respectively.

- Active component and reserve/guard component personnel levels experience some countervailing movement over time. It is not unusual to see the active component swell when the reserve/guard component shrinks, and vice versa. This is especially common at the beginning and end of conflicts, as service members from one are converted into service members in the other. However, it is also common during cutbacks.

- Reserve/guard component personnel spend less time on active duty than active component personnel, and tend to experience proportionally larger swings in total size. DMDC separation records suggest that, in 2013, 75 percent of active component service members separated within 12 years of active service, while 75 percent of reserve component service members separated with less than a year of active duty service.

- Soldiers and Marines had fewer years of active service at the time of separation than did airmen and sailors, on average. DMDC separation records suggest that, in 2013, 75 percent of airmen/sailors separated within 12 years, but 75 percent of soldiers/Marines separated within seven years. Among active component service members, those figures were 15 years and 10 years, respectively.

Model predictions for the cumulative number of separating service members[47] were calibrated against the demographic models discussed in Section 3. Our minimal conflict, permanent drawn scenario assumptions produced the same predicted increase in the size of the post-9/11 Veteran cohort by 2024. Appendix D reports the typical years of service at time of separation for active and enlisted personnel over this time period.

---

[47] Minus those with less than two years of active duty services, and no hostile deployments. For the reserves and National Guard, we made some allowances for those who served a full term for which they were called up, qualifying for VA without serving a full 24 months.

Enrolled VA health care users. Combining these projections with various survey sources, we then calculated how many of these separating service members might go on to rely on VA for at least some of their health care needs. This analysis involved using VA's NSV to calculate the probability that Veterans with different characteristics would enroll in VA health care, and also VA's SoE to ascertain the probability that Veterans with different characteristics would rely on VA for at least some portion of their health care needs. Implicitly, these probabilities are modeling both the chances that a Veteran would be eligible for VA health benefits, and that he or she would choose to enroll and rely upon VA care.

However, implicit in this conversion rate is the assumption that future conflicts will affect the chances of enrollment and reliance in the same way that they did during the 2000–2014 period. For example, one of the reasons why conversion rates are higher for deployed Veterans is that deployed Veterans are more likely to suffer a service connected disability. However, differences in the weapons technology, battlefield medicine, and geographic location of futures conflicts can alter the chances of acquiring such a disability.

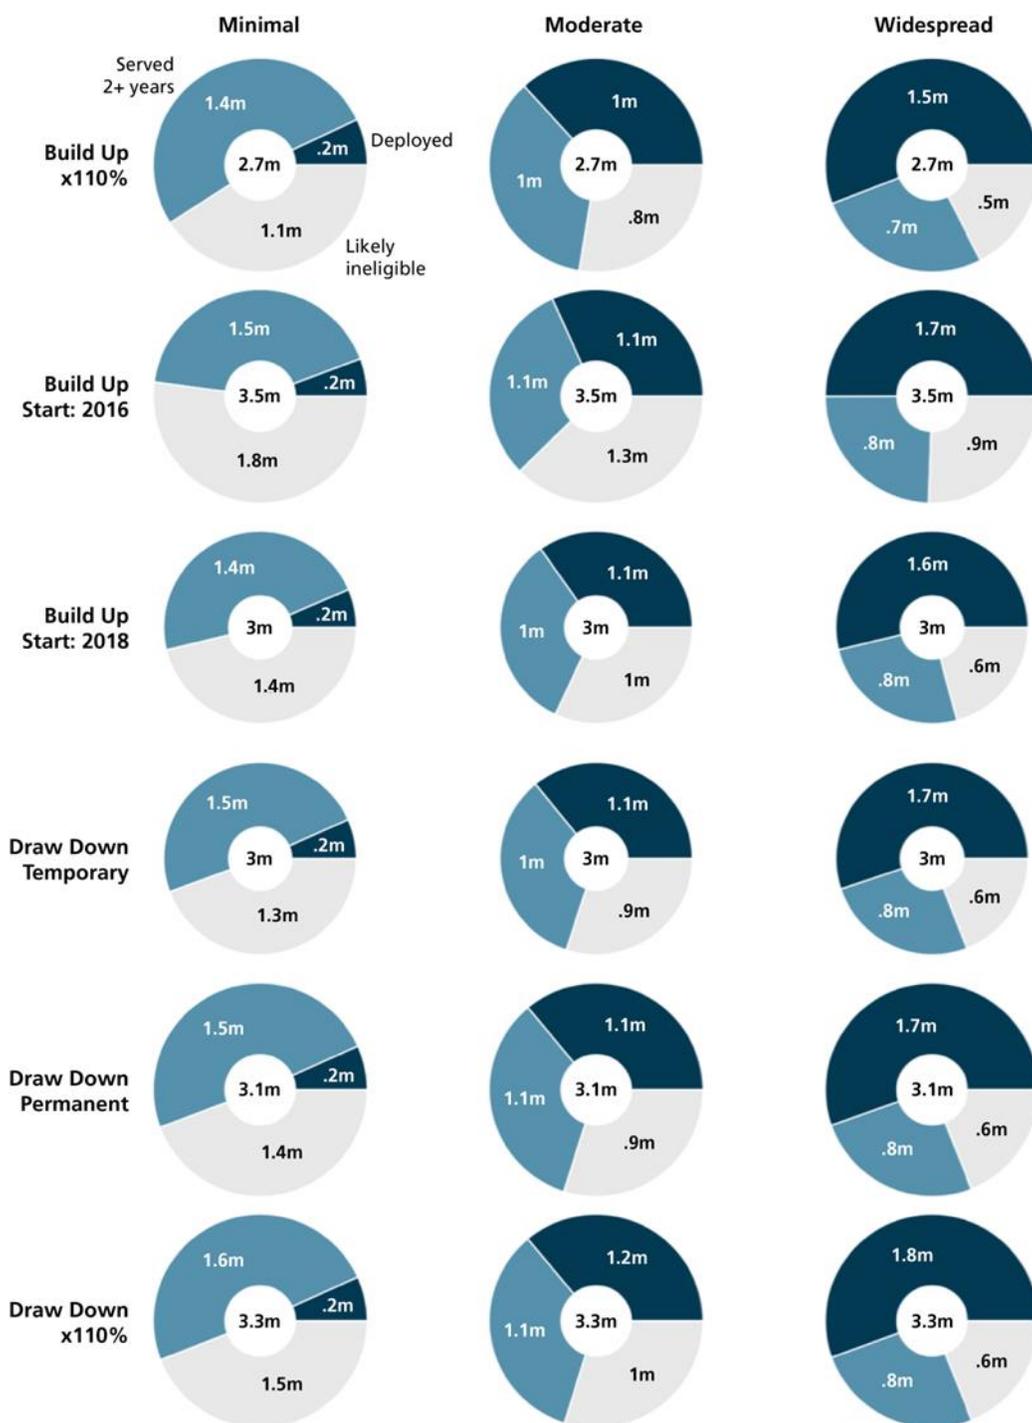
To examine the consequences of such variation, we crafted two scenarios of the chances that separating service members would become VA users. One scenario assumed a 10 percent increase in the conversion rate, while the other assumed a 10 percent decrease in those rates. Our baseline rates were validated against the rates calculated in Section 4. See Section 4 for a more detailed treatment of reliance and enrollment rates.

6.6.3 Results

Figure 6-4 reports the results of 18 projections (the doughnut plots) of separating service members for each of six end-strength scenarios (the rows), and three conflict exposure scenarios (the columns). The size of each doughnut is proportional to the total number of separations projected to take place between 2014 and 2024. The three colors divide the separations into three broad categories: (1) *ineligible*—those with less than 24 months of active duty service and no combat exposure (light gray); (2) *served two or more years*—those who separated with at least 24 months of active duty service, but no combat exposure (medium blue);[48] and (3) *deployed*—those who experienced at least one deployment into a conflict zone before separating (dark blue). These categories are based on the historical maximum, average, and minimum observed deployment rates for each segment of the military during the post-9/11 period. The precise historical figures are reported in Appendix D.

---

[48] Reservists and National Guard personnel who were called-up and served for their full term are counted as having served 2+ years.

Figure 6-4. Cumulative Separations (2015–2024)


SOURCE: RAND calculations based on DoD administrative data (2015), Census Bureau data (2012), Congressional Budget Office analysis (2014), and U.S. Army posture statements (2014).

Across scenarios, the number of projected service members who will separate between 2015 and 2024 varies from 2.7 to 3.5 million. However, a substantial portion, mostly reservists, will not have been on active duty long enough to qualify for VA benefits. That leaves between 1.6

and 2.6 million that will be on active duty for at least two years before separation and/or have experienced a deployment to a hostile area.[49]

Looking across scenarios, the largest increase in end-strength did not necessarily translate into the sharpest increase in separations, because many of those new recruits will remain in service for a number of years afterward. According to DMDC records, 50 percent will still be in service six years later, and 25 percent will still be in service 12 years later. Because the impact of a recruiting surge is diffused over a number of years, the number of separations rises gradually, rather than abruptly. In contrast, drawdowns have a much more immediate effect. When end-strength decreases, additional separations are encouraged through changes in incentives, and these excess separations fully enter the Veteran pool within the first couple of years. Consequently, a recruitment surge would need to be more than three times as large as a drawn down to have the same near-term consequences for VA.

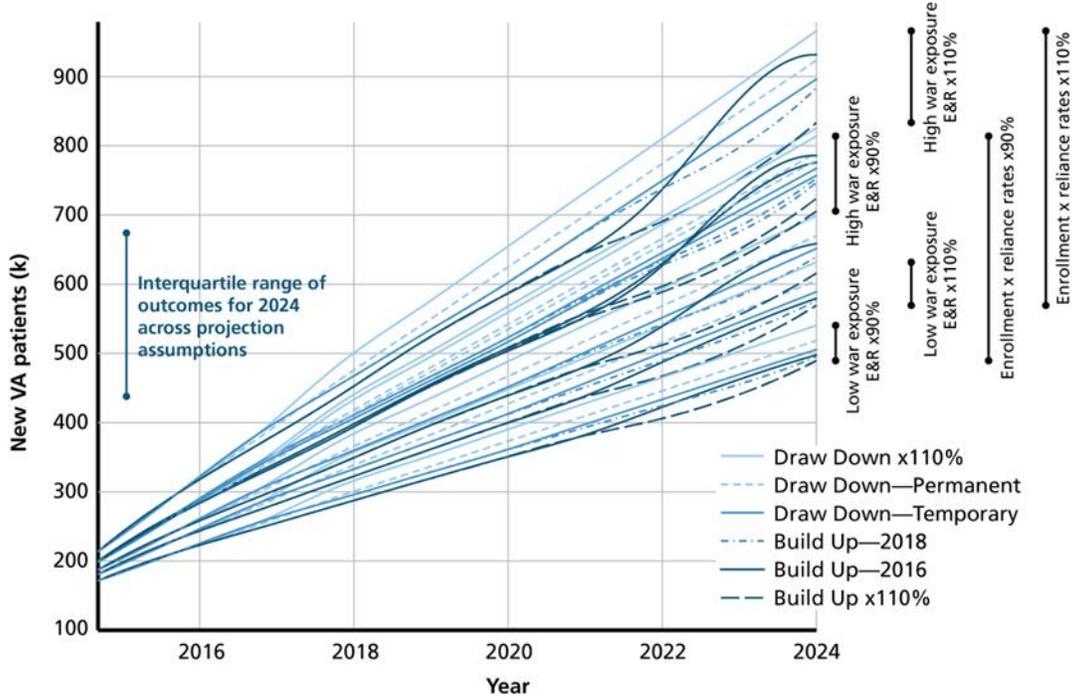
Conflict can have a major impact on how separation translates into potential users of VA services. One major mechanism is activation. Reservists who would not otherwise qualify for VA benefits would become eligible through deployment and active duty service. Conflict exposure itself also carries consequences for eligibility and the chances of relying on VA to provide care. The net result is that conflict can allow even a relatively small cohort of new separating service members to translate into a larger impact for VA, because proportionally more are likely to become users of VA health care. The "Build Up Start: 2016" row examines the volume of separations that might result if the United States began surging toward its historical maximum size in 2016, and then slowly started drawing back down after reaching that maximum. Between 2014–2024, 3.5 million service members were projected to separate. In a minimal conflict scenario, historical rates of deployment (the lowest observed in the post-9/11 period) and reenlistment suggest that approximately 200,000 of them might be deployed, and 1.5 million might spend enough time on active duty to meet VA requirements. In a widespread conflict scenario, historical rates of deployment (the highest observed in the post-9/11 period), 1.7 million might be deployed, and an additional 800,000 would be projected to serve sufficient time on active duty. This would amount to nearly a 50 percent increase in the number of potentially eligible Veterans, and an 850 percent increase in the number of likely deployed Veterans.

Figure 6–5 estimates how many of these separating service members would likely become VA patients under various scenario assumptions. The 36 lines are cumulative, charting how many new users would be likely to have used VA health care by that year under a given set of assumptions. The lines are colored to reflect the end-strength scenario. The black bars on the right identify which subset of lines reflects different sets of conflict exposure and enrollment and reliance assumptions (marked on the chart as E&R). For example, the bar labeled "High War Exposure, E&R x 90%" denotes the assumption that a larger percentage of separating service members will have experienced at least one hostile deployment, but that the conversion rate of separating services members to VA patients will be lower than it was during

---

[49] For reservists and National Guard officers, we account for some basic exceptions to the threshold of 24 months of active service.

the 2000–2014 period. It spans from 700,000 VA patients to a little more than 800,000 VA patients, because all of the scenarios that make this assumption project between 700,000 and 830,000 new VA patients by 2024.

Figure 6-5. Cumulative New VA Patients Under Various Scenario Assumptions


SOURCE: RAND calculations based on DoD administrative data (2015), Census Bureau data (2012), Congressional Budget Office analysis (2014), U.S. Army posture statements (2014), NSV survey responses, and SoE survey responses.

In terms of end-strength, the biggest impacts on the number of additional VA patients occurred in scenarios that involved either a massive drawdown in the size of the military or a surge happening within the next couple of years, followed by ample time to draw back down. However, the total impact of the end-strength scenarios is relatively small compared with the other assumptions—at most generating a difference of about 100,000 patients by 2024.

Our two enrollment and reliance scenarios considered a 20-percent difference in the assumed rate at which eligible separating service members would become VA patients. The projected effect varied greatly, depending on the other scenario assumptions, but may generate up to 150,000 additional patients by 2024.

However, all of these pale in comparison with the effects of conflict exposure as a driver of demand for VA health care. Military conflict affects these projections at multiple stages—raising the number of eligible reservists and National Guard officers, increasing the rate of conversion to VA patients, and so on. Cumulatively, these effects could raise the number of VA patients by 200,000–300,000 over the next decade.

6.6.4 Discussion

Our analysis reveals three major findings. First, while a military buildup would produce more Veterans in the long term, drawdowns create a much steeper annual rise in the size of the Veteran population, because the population impact of a buildup is spread over a larger number of years. Drawdowns are much more likely to require VA to quickly and significantly increase its capacity. A sharp drawdown after a large buildup affects VA more than any other end-strength scenario. Second, conflict exposure increases demand for VA health care more than any other projection assumption. Looking across projections, the smallest wartime cohort of separating Veterans generates more VA usage than the largest peacetime cohort. Third, only some service members will become VA patients. The conversion process—from service member to eligible Veteran to VA patient—plays a significant role in determining how much demand VA would need to meet.

If we reflect on the Afghanistan and Iraq experiences, the past 15 years have witnessed the sequence of events most likely to generate a rise in demand for VA services. The combination of war and sequestration increases future eligibility and demand for VA health care among service members, and then quickly moves those service members into the Veteran pool.

Looking forward to the near future, the majority of our scenarios predicted 500,000 to 925,000 new VA patients by 2024. However, most high-conflict projections estimated 750,000–925,000, while most low-conflict projections estimated just 500,000–600,000 new patients. This suggests that even moderate levels of hostile deployment can have big repercussions for the size of the incoming cohort of VA patients.

However, previous cohorts, especially the Vietnam cohort, were much larger than recent cohorts, so the difference would be small relative to the entire VA user population. To be precise, of the 21.6 million Veterans in 2014, only 2.6 million served during the post-9/11 period. Projecting forward, 1.7 million new post-9/11 Veterans are expected to join that cohort by 2024, while the overall size of the Veteran population declines to 17.5 million. These projections suggest that, depending on end-strength and conflict intensity, the number of new Veterans may vary between 1.6 million and 2.6 million. That amounts to approximately a 50 percent difference in the projected size of the post-9/11 cohort, but only a 5 percent difference in the size of the 2024 Veteran population.

6.7 Improving Access to VA Care

6.7.1 Description

VA has a range of policy tools at its disposal to address actual and perceived barriers to access. The Choice Program, which enables Veterans meeting certain criteria to receive VA-paid care from community providers, is one example. However, other, more-expansive policies are also possible. For example, the Choice Program, which is a temporary three-year program that applies to previously enrolled Veterans only, could be made permanent or expanded to all Veterans. In this scenario, we modeled the potential impact on VA (in terms of new patients) of eliminating all actual and perceived barriers to access, regardless of the policy tool or approach

used. This analysis is a useful bounding exercise for the potential impacts of the policies to improve access. As in other scenarios, we assumed that the underlying VA health care delivery system and access to health care through non-VA channels remain constant over time.

6.7.2 Approach

Data and Methods for Scenario Four, Improving Access to VA Care

- We analyzed Veterans' responses to the 2010 NSV to calculate (1) the proportion of Veterans who selected an access-based reason for never using VA health care and (2) the proportion of Veterans who were VA patients.
- We calculated the number of Veterans who would use VA health care if those who reported access-related reasons for not using VA health care started using VA health care at the same rate as their peers. We did this by multiplying the number not using VA for access-related reasons by the use rate among Veterans who were patients or did not report access-related reasons for not using VA health care.
- We conducted a similar analysis using data from the SoE to determine the number of enrolled non-users who might become VA patients if access barriers were lifted.

We analyzed Veterans' responses to the 2010 NSV to calculate the proportion of Veterans who are not enrolled to receive VA care and who selected an access-related reason for not using VA health care. We also used NSV data to calculate VA use rates for each Veteran subgroup, excluding from the denominator those who reported an access-related reason. In a separate analysis, we used ACS data to estimate the proportion of Veterans in each health insurance coverage subgroup who are eligible to receive VA services. Our approach for this last analysis is outlined in detail in Section 6.4 and Appendix D.

We combined these inputs to calculate the number of Veterans who might enroll in and use VA health care if access improved. More specifically, we calculated the number of potential new VA patients if Veterans who we estimate to be eligible for VA care and who reported access issues started using VA services at the same rates as Veterans who did not report access problems.

We repeated these steps for Veterans who are enrolled to receive VA care but are not current VA patients using the 2013 SoE. While NSV and SoE both describe Veterans' reported access-related reasons for not using VA health care, the two surveys sample different populations and offer complementary insight into how use of VA health care might change if access improved. Unlike SoE, NSV surveys Veterans who are not currently enrolled to receive VA health care services. This population of Veterans is important in our analyses because if access to VA care improved, we would expect additional Veterans to enroll to receive VA health care services. While SoE has a larger sample size and is more recent than NSV (2013 versus 2010), it is limited to enrolled Veterans only. Both surveys have information on enrolled Veterans who choose not use VA health care services. We present results from both surveys in an effort to present a range of plausible impacts if VA were to improve access to its health care.

In addition to the analyses described above, we fitted multivariate logit models using NSV data to describe how various characteristics of Veterans predicted the likelihood of self-reporting one or more access-related reasons for non-use.

Using this approach, we acknowledge that some Veterans would choose not to use VA health care even if there were no actual or perceived access, quality, or other differences between VA care and community-based care. The number of Veterans who choose to become new VA patients is affected by many factors, including access to other sources of health coverage and other features of the conceptual model described in Figure 2-1.

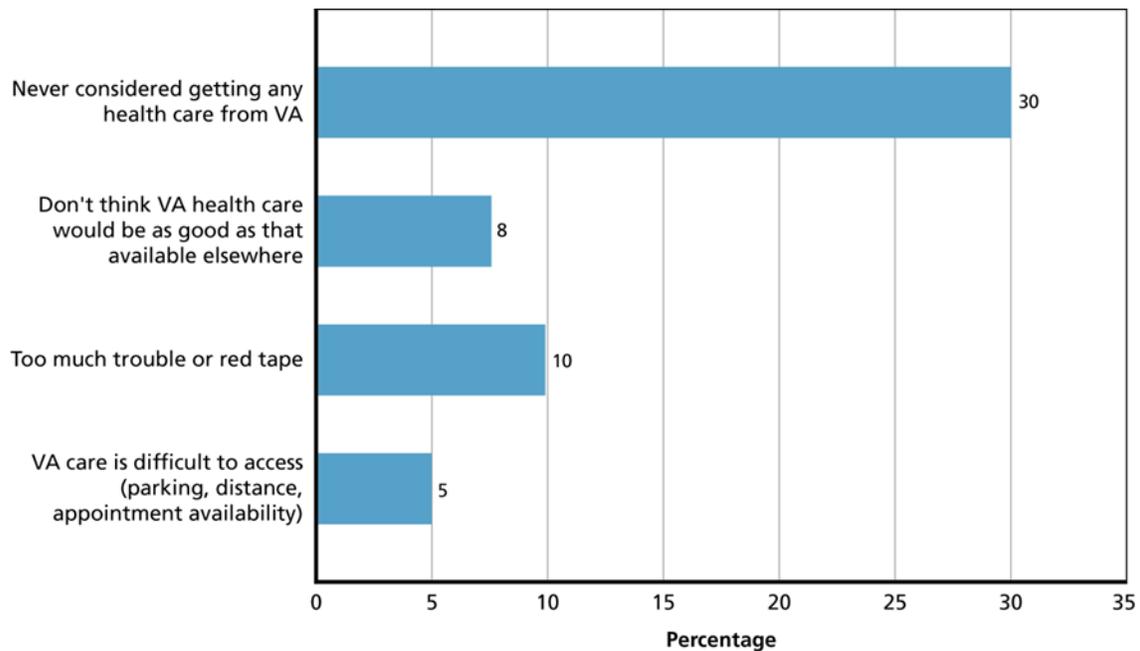
6.7.3 Results

6.7.3.1 NSV Analyses

We found that a significant share of Veterans reported an access-related reason for not using VA health. Of the 14.8 million Veterans who self-reported that they never used VA health care benefits, 1.8 million (or 12.4 percent of non-users) reported not using VA care because either "VA care is difficult to access (parking, distance, appointment availability)" or there was "too much trouble or red tape" (Figure 6-6).[50] Many of the choices available to respondents—for example, "never considered getting any health care from VA" or "don't think VA health care would be as good as that available elsewhere"—are broad responses that could reflect access, convenience, amenity, and quality of care reasons for not receiving care. The actual number of Veterans not using VA care who experienced access problems may be higher than the 12.4 percent noted above, to the extent that these Veterans selected more-general responses in lieu of specific responses related to access.

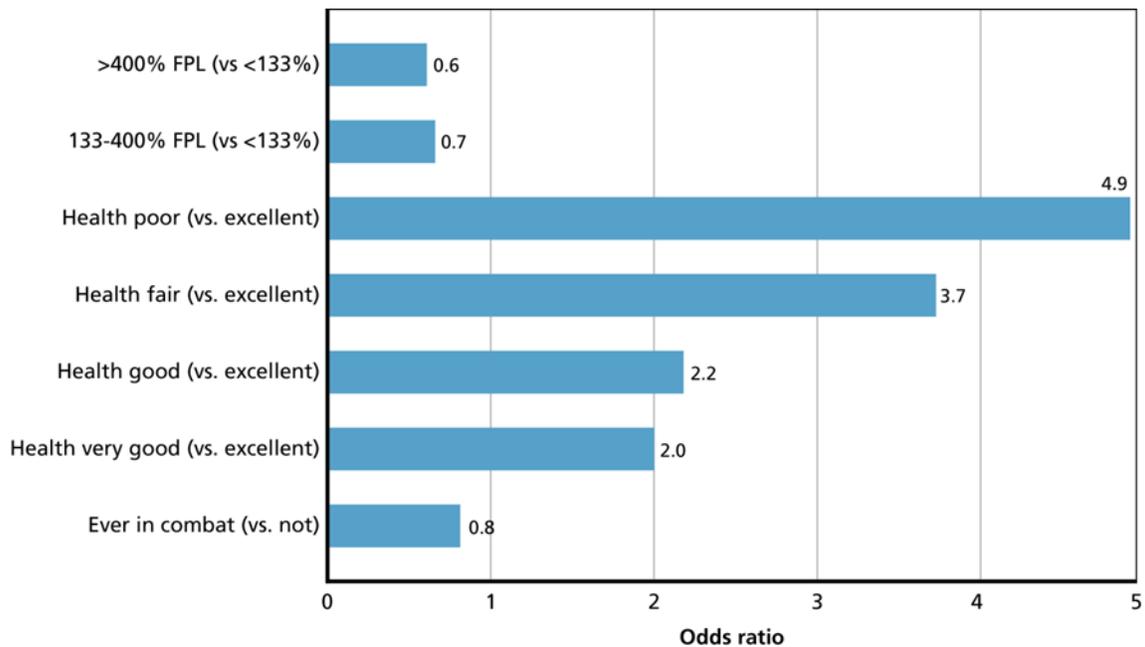
---

[50] Note that some respondents selected both reasons, and therefore the combined rate is not the sum of the two rates reported in Figure 6-6.

Figure 6-6. Selected Reasons for Not Utilizing VA Care (percentage of non-user Veterans)


SOURCE: RAND analysis of 2010 NSV data (Item E2).

Next, we considered whether certain Veteran characteristics were associated with self-report of an actual or perceived access issue. The results from multivariate models suggested that some Veteran characteristics increased the odds of a Veteran reporting either "VA care is difficult to access" or "Too much trouble or red tape" as the reason why he or she has not used VA health care in the past (Figure 6-7). Non-patient Veterans with incomes greater than 133 percent of the federal poverty level (FPL) were less likely to report one of these two reasons than non-patient Veterans with incomes under 133 percent of the FPL. Non-patient Veterans with poorer self-reported health status had increasingly higher odds of reporting one of these two reasons compared with non-patient Veterans self-reporting that they were in excellent health. Odds ratios for age, sex, service branch, and residence Census region were not statistically distinguishable from 1 and were not included in Figure 6-7.

Figure 6-7. Relationship Between Veteran Characteristics and Self-Reported Access Barriers


SOURCE: RAND analysis of 2010 NSV data.
NOTES: Odds ratios less than 1 imply that the Veteran subgroup has a lower likelihood of reporting an access-related reason for non-use than the reference group noted in parentheses. For example, Veterans at or about 400 percent of the FPL are 60 percent as likely to report an access-related reason than Veterans below 133 percent of the FPL. Likewise, odds ratios greater than 1 indicate that the group has a higher likelihood of reporting an access-related reason for non-use than the reference group.

Table 6-4 reports estimates of the number of Veterans who are not VA patients and who report an access-related reason for their non-use in NSV; the proportion of Veterans in each coverage category that we estimate are eligible to receive care; the utilization rate for Veterans in subgroups by other health insurance coverage who did not report an access issue; and an upper bound estimate of new patients that VA should expect if all non-patients reporting access-related reasons for their non-use became VA patients at the same rates as their peers. The bulk of new patients would have private health insurance, Medicare coverage, or no coverage other than VA. We estimated that an upper bound of 235,000 Veterans who were formerly not VA patients might start using VA care if there were no access barriers in the VA health care system.

Table 6-4. Upper Bound of New Patients Responding to Improved Access

Population	Non-Patients Reporting an Access Reason (thousands)	Proportion of Veterans Eligible to Receive Care (%)	Use Rate (%)	Upper Bound of New Patients (thousands)
No Coverage or VA only	122	60	52	**38**
Private only	811	28	19	**43**

6.7.3.2 SoE Analyses

In order to explore how the elimination of access-related barriers would influence patient counts among current enrollees, we identified five SoE items that are most closely aligned with Veteran access to care:

1. "Veterans like me can get in and out of an appointment at VA in a reasonable time."
2. "When Veterans like me go to VA for an appointment, they do not wait a long time to see the doctor."
3. "It is easy to get to my local VA facility."
4. "There is a VA provider in my area that offers all of the health care services that Veterans like me need."
5. "It is easy for Veterans like me to get around in the VA health care facility."

Overall, 13 percent of Veterans who are not patients reported that they "completely disagreed" or "disagreed" with at least one of the five items listed above.

We multiplied SoE estimates of the number of enrolled Veterans who were not 2013 VA patients by the proportion of non-patient Veterans in each age category reporting a potential access problem (columns A through C in Table 6-5). We then assumed that, at most, these Veterans would begin using VA health care at the same rates as Veterans in the same age band,

excluding all Veterans who reported potential access problems (column D).[51] The resulting estimate is 212,000 new VA patients if all access barriers were eliminated.

Table 6-5. Upper Bound of New Patients Among Enrolled Veterans Responding to Improved Access

Population	A. Total Enrollees who were Not Patients in 2013 (thousands)	B. Proportion of Veterans Responding "Disagree" or "Completely Disagree" to an Access Item (%)	C. Non-Patients Reporting Access Reason (thousands)	D. Use Rate (%)	E. Upper Bound of New Patients (thousands)
Age 18–44	399	11.8	47	70.6	33
Age 45–64	735	11.5	85	78.8	67
Age 65+	1,047	14.0	148	75.4	111
Total	**2,181**	**12.8**	**279**	**76.0**	**212**

SOURCE: RAND analysis of 2013 SoE data.

6.7.4 Discussion

Even with nearly 2 million Veterans reporting an access-related reason for not using VA care in NSV, low use rates overall imply relatively small changes in new VA patients if access barriers were lifted. If non-patient Veterans reporting access issues started using VA care at the same rates as their peers who do not report access problems, we estimate that 235,000 Veterans will become new VA patients. Our complementary analysis of SoE data suggests that improving access to VA care could lead to an additional 212,000 currently enrolled Veterans opting to use VA care. The estimates from SOE are slightly lower than the estimates from NSV, in part because NSV includes all Veterans, while SOE focuses on enrolled Veterans only.

Our analysis made two important assumptions. First, we assumed that NSV and SoE accurately identified the proportion of non-VA-patient Veterans with an actual or perceived barrier to access. Neither survey is explicitly designed for this purpose, and neither directly asks Veterans to report or describe access barriers. VA would benefit from future surveys focusing specifically on the relationship between Veterans' perceptions of VA care and their decision of whether to receive care from VA. Second, we assumed that Veterans reporting access issues would use VA services at the same rates as their peers if actual or perceived access issues were to disappear. The actual use rate for these Veterans might be higher or lower than what we observed in survey data.

Despite these limitations, our analysis suggests that policies to improve access will have a modest impact on number of new VA patients. The relatively small effect reflects that many Veterans choose to receive some or all of their care from non-VA sources for reasons that do not appear to be entirely related to access. Additional data collection and analysis are needed

---

[51] We calculated this hypothetical use rate by dividing the number of VA patients in each age band by the sum of the number of patients and the number of non-patients who did not report an access issue in each age band.

---

to better understand the drivers of Veterans' decisions to use VA care rather than their other coverage. These inputs could be used to better predict how Veterans would respond—in terms of enrollment and utilization—to specific improvements in access to VA-provided care or wider availability of VA-purchased care.

6.8 The Affordable Care Act's Coverage Expansion

6.8.1 Description

The ACA introduced dramatic changes to the U.S. health insurance and health care delivery landscape. The ACA aimed to increase health insurance rates through several channels. First, the ACA as originally implemented would have expanded Medicaid eligibility to 133 percent of the FPL across the United States.[52] A 2012 Supreme Court decision (*National Federation of Independent Business v. Sebelius*, 2012) left the decision to expand or not expand Medicaid to the states. As of April 2015, 33 states have expanded or are considering to expand Medicaid. Second, the ACA created insurance Marketplaces operated by the states or federal government, paired with subsidies for low-income individuals and penalties for individuals who remain uninsured (Kaiser Family Foundation, 2015). The ACA also instituted an individual mandate requiring most people to obtain insurance, an employer mandate requiring that businesses with 50 or more workers offer coverage, and numerous other reforms.

The specific scenario that we evaluate focuses on the ACA's coverage expansion provisions. These include:

- *Medicaid expansion* enabling all individuals in participating states with family incomes at or below 133 percent of the FPL to enroll in the Medicaid program.
- *Subsidies for Marketplace insurance*, which are available to individuals with incomes between 100 and 400 percent of FPL who are not eligible for Medicaid and who do not have an affordable offer of coverage from an employer. The ACA's Marketplaces are online portals for buying and selling individual market (that is, non-employer) coverage. Individuals with incomes between 100 and 133 percent of the FPL are eligible for Medicaid in expansion states and Marketplace subsidies in non-expansion states.
- *The individual mandate,* which requires most Americans to obtain health insurance or pay a tax penalty.
- *The employer mandate,* which requires businesses with 50 or more workers to offer health insurance coverage or face penalties. In practice, the employer mandate has little effect on our analysis, because most employers with 50 or more workers offered insurance before the ACA was enacted and will continue to do so in the future.

The ACA includes a wide range of other provisions, including payment and delivery demonstrations, prohibitions on co-payments for preventive care, and taxes on expansive

---

[52] Due to a 5-percent income "disregard" that is part of the modified adjusted gross income threshold used to determine Medicaid eligibility, the effective income threshold is 138 percent of the FPL. We use 133 percent of the FPL throughout this report for consistency.

employer-provided health insurance plans. While these dimensions of the ACA are not explicitly considered in our coverage expansion scenario, we touch on many of these issues in this subsection.

By February 2015, 11.7 million people were enrolled in Marketplace plans (Office of the Assistant Secretary for Planning and Evaluation, 2015b) and an additional 11.7 million people were newly enrolled in Medicaid and the Children's Health Insurance Program (Centers for Medicare & Medicaid Services, 2015a). Recent survey-based research confirms significant gains in coverage (Carman & Eibner, 2014; Long et al., 2013; Sommers et al., 2014), although the net decrease in uninsured rates reflects the fact that some people gaining Medicaid or Marketplace coverage previously had other sources of coverage. One group that is of particular interest to policy-makers and researchers is the set of people in the so-called "coverage gap"—that is, low-income individuals who lack affordable coverage options because they may not qualify for Marketplace subsidies and are in a state that opted not to expand Medicaid (Garfield, Damico, Stephens, & Rouhani, 2014).

While the ACA did not directly affect Veterans' eligibility to enroll in or receive VA care, there are important spillover effects of the ACA coverage expansion on Veterans and, ultimately, VA. Some uninsured Veterans may choose to enroll in VA health care to obtain qualifying coverage and avoid individual mandate penalties (U.S. Department of Veterans Affairs, 2015d). Other uninsured low-income Veterans, including some who were previously enrolled to receive VA health care or expect to use VA health care in the future,[53] may qualify for subsidies to purchase coverage in insurance Marketplaces, or they may live in states that opted to expand Medicaid. These individuals may transition out of the VA health care system and into the community setting to receive some or all of their care.

The net impact of the coverage expansion on VA depends on the number of Veterans who face new incentives to enroll in VA health care compared with the number of current VA patients who obtain new private or Medicaid coverage and opt to shift to non-VA, community-based providers. Analysis of Veterans' incomes in the 2013 ACS suggests that more than half of Veterans report family income of less than 400 percent of the FPL, which is the threshold for eligibility for Marketplace subsidies (Table 6-6). Approximately 13 percent of Veterans fall below 133 percent of the FPL threshold for Medicaid eligibility in expanding states. These proportions are similar in states that are and are not expanding Medicaid. Based on self-reported income alone, it appears that the health care decisions for a significant share of Veterans could be influenced by Marketplace subsidies or Medicaid expansion. Because our analysis considered states' decisions to expand Medicaid, it also took into account the geographic distribution of Veterans. Veterans who live in non-expansion states are therefore

---

[53] Individuals who have an offer for "qualifying coverage" are not eligible to receive ACA subsidies. Enrollment to receive VA health care is considered qualifying coverage (U.S. Department of Veterans Affairs, 2015d). However, it is not clear whether there are processes in place to prevent a Veteran currently enrolled in VA health care from receiving subsidies to purchase care through an insurance Marketplace. Veterans may need to dis-enroll from VA health care in order to qualify for ACA subsidies.

less likely to gain a new source of insurance under the ACA than Veterans who live in expansion states.

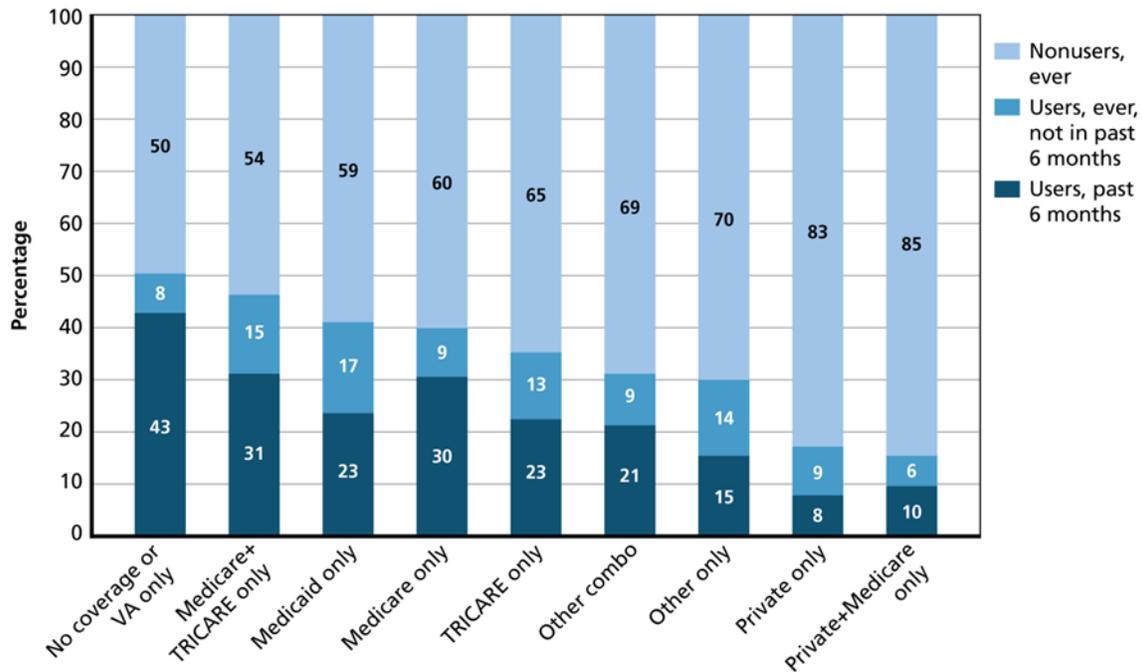
Table 6-6. Distribution of Veterans by Income and State Medicaid Expansion Decisions

Income Relative to the Federal Poverty Limit	States Expanding Medicaid,[a] Percentage of Veterans	States Not Expanding Medicaid,[a] Percentage of Veterans
< 100% FPL	4.8%	4.1%
100–133% FPL	2.5%	2.2%
134–400% FPL	23.3%	19.4%
> 400% FPL	24.8%	18.8%
Subtotal	**55.4%**	**44.6%**
Total	**100%**	

SOURCE: RAND calculations using 2013 ACS PUMS.

[a] States announcing expansion by April 2015 are included in the expanding category (Kaiser Family Foundation, 2015). Four states (Alaska, Florida, Missouri, and Utah) that are considering expansion are included in the not expanding category.

The net impact also hinges on the proportion of Veterans in different populations who use VA services at all each year, or the *use rate*. Many Veterans have at least one other source of health insurance coverage other than VA health care, and Veterans with other coverage have markedly different use rates than Veterans without other sources of coverage. Slightly more than half of Veterans reporting no non-VA sources of coverage have used VA health care services in the past, and 43 percent report using VA health care services in the past six months (Figure 6-8). Only 8 percent of Veterans reporting private coverage alone report using VA health care in the past six months.

Figure 6-8. VA Health Care Use Rates, by Veteran Health Insurance Coverage


SOURCE: RAND analysis of 2010 NSV, items E2, E3, and F1, weighted by sampling weights.

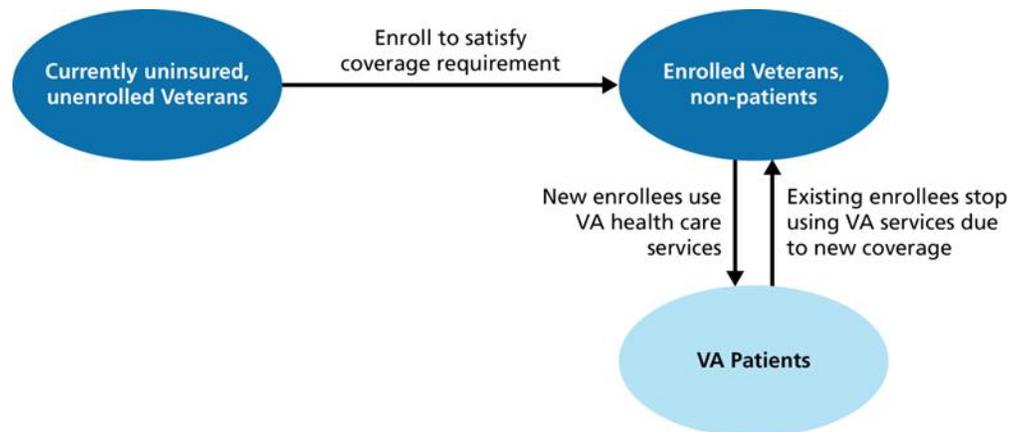
The key assumptions underlying the ACA coverage expansion scenario center on whether and how Veterans who change their coverage status will change the way that they use VA health care. For example, VA health care enrollees who gain Marketplace or Medicaid coverage could continue to use VA health care as before the ACA, or they could shift to community providers and reduce or stop using VA health care. Many of the ideal inputs for evaluating the impact of the coverage expansion on VA are not yet available for analysis. We propose a set of "base case" coverage changes, enrollment rate, and use rate assumptions to illustrate key analytic steps and impacts. We also describe the implications of different assumptions in Appendix D.

6.8.2 Approach

Data and Methods for Scenario Five, Impact of the Affordable Care Act (ACA)

- We estimated the impact of two effects of the ACA's coverage expansion: (1) enrollment of previously uninsured Veterans in response to the individual mandate and (2) uptake of new private and Medicaid coverage by Veterans currently enrolled in and using VA health care. We used NSV data to estimate both the number of uninsured, under-65 Veterans (those not enrolled in VA and with no other source of coverage) and the number of under-65 Veterans enrolled in VA care but with no other source of coverage.
- We then analyzed these estimates to determine how many Veterans would obtain coverage through the ACA and assessed whether and how Veterans who change their coverage status because of the ACA will change the way they use VA health care services.

We separately estimated the impact of two countervailing effects of the coverage expansion: (1) enrollment of previously uninsured Veterans to gain qualifying health coverage and avoid individual mandate penalties, some of whom will actually use VA services and some of whom will enroll only to avoid penalties, and (2) uptake of new private and Medicaid coverage by Veterans currently enrolled in and using VA health care. Figure 6-9 illustrates these effects. If the outcome of interest is the number of VA patients, then the two key flows are those to and from VA patients. The net impact of the coverage expansion is the flow of new, previously uninsured patients minus the flow of current patients who transition entirely to other sources of care.

Figure 6-9. Coverage Expansion Patient Flows


The net change in terms of patient counts nationally may be small when considering both impacts. However, individual shifts within demographic and priority group categories may be significant and important for VA to incorporate into its modeling activities. For example, low-income Veterans in states that chose to expand Medicaid eligibility may be less likely to use VA health services than their peers in states that opted not to expand Medicaid. Based on our

---

review of the 2014 EHCPM model documentation, we do not believe that the most-recent VA projections of demand reflect any ACA-related changes in the enrolled population or use rates.

We used NSV data to estimate the number of uninsured Veterans—that is, Veterans who are not enrolled in VA health care and have no other source of coverage. We also used NSV data to estimate the number of Veterans who are enrolled in VA health care but have no other source of coverage. We then estimated how many of these Veterans would enroll in health insurance coverage in 2016 as a result of the ACA, ignoring their eligibility for VA health care. This analysis allowed us to separate the uninsured, non-enrolled Veteran population into two groups: (1) those who without VA eligibility would gain health coverage through the ACA and (2) those who would remain uninsured. We limited our analysis to Veterans under age 65, because most Veterans over age 65 are enrolled in Medicare, and because those age 65 and over are ineligible for the ACA's Medicaid expansion and Marketplace subsidies.

The estimate was based on results from the RAND COMPARE (COMPrehensive Assessment of Reform Efforts) microsimulation model, which is a model built to estimate the effects of the ACA (Cordova, Girosi, Nowak, Eibner, & Finegold, 2013). The model takes into account the four coverage expansion provisions described above, as well as changes to insurance regulations that will affect health insurance premiums and, consequently, enrollment decisions. The model also accounts for the ACA's effects on employers, although, in net, we estimate little impact on employer health insurance provision. We focused on individuals in the general population with the same age distribution as uninsured, non-enrolled Veterans. We calculated the number of Veterans who would be expected to enroll in Medicaid, Marketplace plans, or other private coverage by combining the estimates of Veteran populations with the coverage change estimates from COMPARE.

While we could estimate with some accuracy the number of Veterans who would be eligible for Medicaid and for subsidized health coverage through the Marketplaces, predicting their choice to take up this coverage, enroll for VA coverage, or remain uninsured is much more difficult. This is true for both those Veterans currently enrolled at VA and those not enrolled. While we begin with a set of baseline enrollment and use rates with some grounding in observed rates in the Veteran population, it is important to recognize that actual enrollment and use rates are not known and may deviate from the enrollment and use patterns observed in current Veteran and patient data.

We expect that Veterans with different health coverage options will enroll in VA health care at different rates; we assume that Veterans who are eligible for Marketplace subsidies will be less likely to enroll in VA than Veterans who are not eligible for subsidies, and Veterans who gain access to Medicaid will be less likely to enroll in VA than Veterans who gain Marketplace subsidies. We began by setting a base rate for the percentage of uninsured, non-enrolled Veterans who we predict will not gain coverage under the ACA. We applied this same base rate to Veterans over 400 percent of the FPL who we predict will gain coverage. These Veterans will not have access to subsidized coverage under the ACA. We set the enrollment rate for Veterans who we predict will gain coverage and can receive Marketplace subsidies at half of the base rate, to reflect that subsidies may make Marketplace coverage an attractive option, particularly for Veterans who had not enrolled previously in VA care. We assumed that Veterans who will

gain coverage through Medicaid will enroll in VA health care at one-quarter of the base rate, reflecting Medicaid's minimal cost-sharing requirements.

We assumed that Veterans induced by ACA to enroll in VA health care use VA services at the rate observed for the entire under-65 Veteran population with private insurance only. While this is lower than the use rate for enrolled Veterans overall, it reflects the fact that some Veterans will enroll solely for the purpose of obtaining qualifying coverage. As we note below, the use rate for these Veterans may increase over time. We report results for a range of enrollment and use rates in Appendix D.

Finally, we did not explicitly account for changes in use rates due to ACA-driven changes in VA priority group assignment. For example, in theory, Veterans could move from priority group 7 to priority group 5 if they live in a state with Medicaid expansion and now qualify under the higher-income threshold. The move to priority group 5 would face no cost-sharing for VA health care. However, the income threshold for priority group 5 is considerably higher than the higher Medicaid threshold, so we do not believe Medicaid expansion will affect the number of Veterans in priority group 5. More generally, the larger change for these Veterans is that they are gaining a new source of coverage from Medicaid, and we expect this change rather than a reduction in VA cost-sharing to be the more important driver of whether the Veteran chooses to become a VA patient.

6.8.3 Results

The following two subsections report separate results for the two flows of patients in Figure 6-9—first, a flow of new enrollees and patients from previously uninsured Veterans, and second, a flow of patients away from VA health care as they gain other coverage. A third subsection reports net results after combining these two components.

6.8.3.1 New Enrollees and Patients from the Previously Uninsured

If the post-ACA coverage transitions of Veterans were to resemble those for the general population, we estimate that half of the 1.1 million uninsured, non-enrolled Veterans in 2013 would enroll in another source of coverage—for example, Medicaid coverage or coverage through a Marketplace plan—by 2016. This rate would be lower for uninsured Veterans under 133 percent of the FPL, because not all states have expanded Medicaid. The remaining half of uninsured Veterans would be expected to remain uninsured through 2016. Table 6-7 reports the number of non-enrolled, uninsured Veterans by income category, the proportion of Veterans in each category to gain coverage, and the resulting number of Veterans predicted to gain other coverage. As a reminder, these results predict what uninsured Veterans would do if they did not have the option to enroll at VA. They are useful for identifying how many uninsured Veterans would choose to gain coverage and face a decision between ACA options and VA coverage, and how many would only consider whether to enroll at VA to avoid paying the penalty for being uninsured.

Table 6-7. Coverage Changes Under ACA for Previously Uninsured Veterans, by Income Category

Income Category	Non-Enrolled, Previously Uninsured Veterans (thousands)	Proportion Predicted to Gain Other Coverage (%)	Non-Enrolled, Previously Uninsured Veterans Predicted to Gain Other Coverage (thousands)
≤ 133% FPL	588	34.4	202
134–400% FPL	390	68.8	268
> 400% FPL	132	62.7	83
Total	**1,109**	**49.9**	**553**

SOURCE: Authors' analysis based on 2010 NSV data and the RAND COMPARE microsimulation model.

Not all uninsured Veterans are eligible to receive VA health care. We used eligibility rates calculated from ACS data and for specific income bands (as described in more detail in the changes to VA eligibility scenario) to estimate the proportion of Veterans eligible to enroll in VA care (Table 6-8).

Table 6-8. Eligibility for Previously Uninsured Veterans, by Income Category

Income Category	Non-Enrolled, Previously Uninsured Veterans (thousands)	Proportion Eligible to Receive VA Health Care (%)	Eligible, Non-Enrolled, Previously Uninsured Veterans (thousands)

The next steps estimate what proportion of Veterans will (1) enroll in VA health care and (2) become VA patients. Table 6-9 (column A) tracks these steps, starting with estimates of VA eligible, non-enrolled, previously uninsured Veterans from Table 6-8. Approximately one in four Veterans is currently enrolled to receive health care services, although the enrollment rate is significantly higher (47 percent) for Veterans without other sources of coverage. We apply a 50-percent enrollment rate for Veterans not predicted to enroll in another source of coverage as a result of the ACA. For Veterans who we predict will enroll in other coverage, we apply the same 50-percent enrollment rate for Veterans in the highest income category and lower enrollment rates for Veterans in lower income categories (because these individuals are ineligible for the ACA's subsidies), as discussed above: 25 percent for those who are eligible for Marketplace subsidies and 12.5 percent for those who enroll in Medicaid. With these enrollment

assumptions, we estimate an increase of 300,000 Veterans enrolled in VA health care (column C in Table 6-9).

Table 6-9. Predicted VA Enrollees and Patients

Income Category	A. Non-Enrolled, Previously Uninsured Veterans Gaining Coverage Under ACA (thousands)	B. Enrollment Rate (%)	C. Predicted Enrollees (Thousands)	D. Use Rate (%)	E. Predicted Patients (Thousands)

SOURCE: Authors' analysis based on 2010 NSV data, 2013 ACS PUMS data, and the RAND COMPARE microsimulation model.

Our next step was to convert these estimates of new enrollees to estimates of new patients. We used a real-world use rate—calculated across enrolled and non-enrolled Veterans with private insurance—for this analysis (column D in Table 6-9).[54] In the short term, Veterans enrolling only to satisfy the ACA's individual mandate may have relatively low use rates compared with patients with private coverage. At a 50-percent base enrollment rate and the use rates described above, we estimated that ACA coverage expansion will result in 70,000 new VA patients who were previously uninsured and not enrolled (column E in Table 6-9).

A limitation of this analysis is that we had to make relatively strong assumptions about which Veterans would enroll and use care due to the ACA's individual mandate requirements. In Appendix D, we conduct sensitivity analyses to estimate how the results might change under a variety of alternative assumptions about enrollment and use rates.

6.8.3.2 Transitions Away from VA Health Care Due to New Coverage Options

Using NSV data, we estimated that there were 1.4 million Veterans enrolled in VA health care without another source of health coverage (column A in Table 6-10). Of these Veterans, approximately half would gain another source of coverage as a result of the ACA (column A in Table 6-10). How many would take up this other coverage is unknown.

The current use rates for this subpopulation of Veterans—that is, Veterans who are enrolled in VA health care and have no other source of coverage—are high (column D in Table 6-10). We

---

[54] We used the private use rate rather than a combination of private and Medicaid use rates because there are very few Veterans with Medicaid coverage only in the NSV data.

assumed that use rates would fall by 25 percent for Veterans who gain other coverage (column E in Table 6-10). If all VA-enrolled Veterans who could enroll in ACA coverage do so and immediately shift to this lower use rate, we would expect 164,000 fewer VA patients each year (column F in Table 6-10). The magnitude of this impact hinges on the ACA take-up rate and the use rate assumption. We discuss the impacts of different use rate assumptions in Appendix D.

Table 6-10. Predicted Coverage Changes for Veterans Enrolled in VA Health Care Only, by Income Category

Income Category	A. Veterans Enrolled in VA Health Care Only (thousands)	B. Proportion Gaining Coverage (%) (RAND COMPARE)	C. 6.8.3.3 Net Impacts and Medicaid Expansion in All States

The net overall change in VA patients hinges on assumptions for enrollment and use rates. Using the base rates described above, we estimated a net decrease of 94,000 VA patients (70,000 new users, minus 164,000 current users who stop using VA care). However, other rates can lead to increases in the number of VA patients.

We looked separately at the impact of Medicaid expansion in every state. Some states that have yet to expand Medicaid are considering doing so, and it is possible that others will follow suit. If we apply the change in Medicaid enrollment that we have observed to date in expanding states to non-expanding states, Medicaid expansion in all states results in 28,000 fewer VA patients.[55] The net impact on VA from broader Medicaid expansion—including the decrease from the base case analysis—is a decrease of 122,000 VA patients.

6.8.4 Discussion

Our analysis suggests that the net impact of the ACA coverage expansion in terms of VA patients is modest, with a net decrease of about 94,000 VA patients per year. However, this net result combines separate flows of Veterans in and out of VA health care, and different assumptions can result in a range of net impacts, including increases in the number of VA patients. We expect that Veterans enrolling in Medicaid to gain qualifying coverage will use VA

---

[55] Our estimate of 30,000 fewer patients includes 8,000 fewer new patients, as more Veterans opt for Medicaid to gain qualifying coverage, as well as 22,000 fewer patients among the already enrolled, as more Veterans access care through Medicaid.

---

care at rates different from current enrollees without other sources of coverage. Specifically, we predict that they will use VA care at rates that more closely resemble current enrollees with access to private care or lower. A large proportion of these Veterans may not need or want to receive VA care, but rather are enrolling to satisfy the ACA individual mandate. Over time, these Veterans may start using VA care at higher rates. Finally, whether current VA patients take up offers for coverage through Medicaid or Marketplace plans hinges in part on their satisfaction with VA health care as their primary source for care, on Marketplace subsidies, and on family composition. For example, Veterans seeking coverage for themselves and dependents may be better served by enrolling in a Marketplace or other commercial family plan rather than enrolling in VA.

6.9 Summary of Scenario Impacts

Table 6-11 and Figure 6-10 summarize impacts of all scenarios on projected patient counts. The table shows only mid-range estimates for each scenario. However, there is considerable uncertainty about the factors behind these estimates. More-sophisticated analysis of Veteran health coverage decisions given the characteristics of the choices available to Veterans was not possible in the limited time for this study, but such analysis could help VA anticipate future changes in its patient population under these and other possible scenarios.

Table 6-11. Scenario Impacts on Projected VA Patient Counts

Scenario	VA Patients, 2014-2024										
	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024

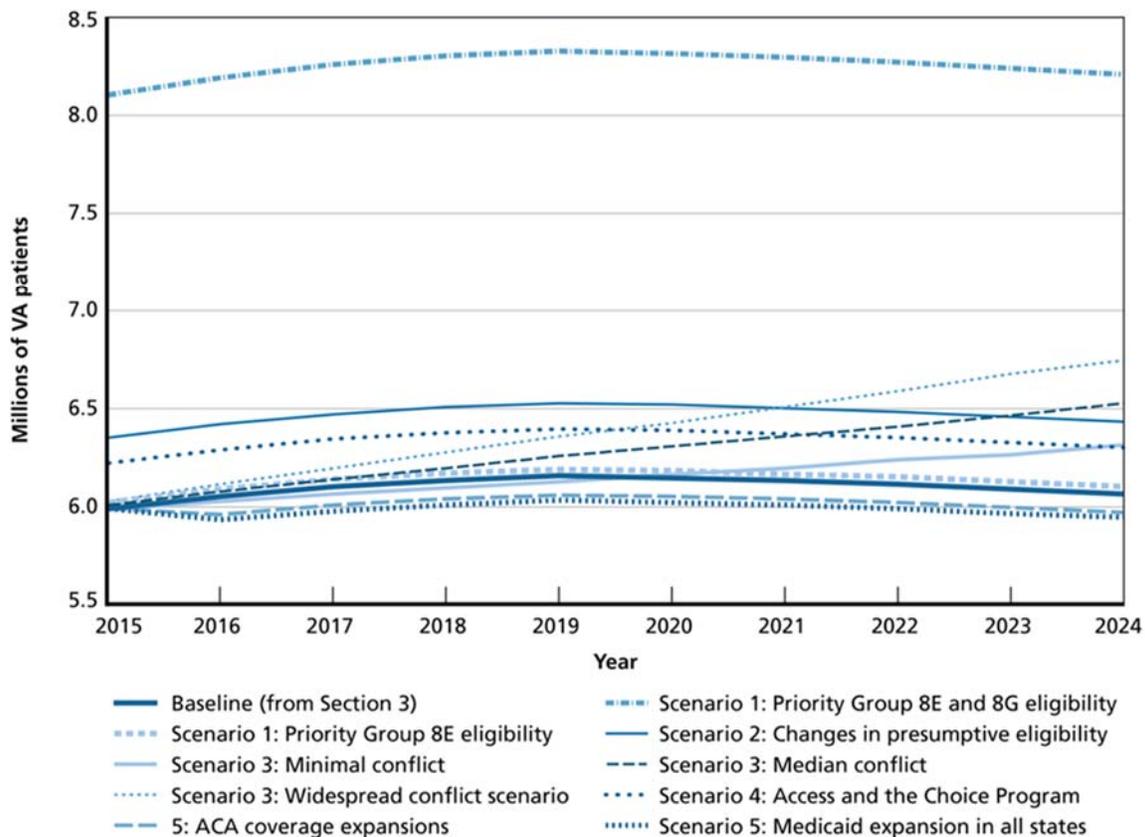
ACA Medicaid Expansion	5.87	5.99	5.94	5.98	6.01	6.03	6.03	6.01	5.99	5.97	5.95

Figure 6-10. Scenario Impacts on Projected VA Patient Counts


6.10 Discussion

The five specific scenarios help quantify the impacts of "what if" policy and trend questions on baseline projections. The impacts of some scenarios, like the priority groups 8e and 8g scenario and, to a lesser extent, the access and presumptive eligibility scenarios, suggest significant increases in the VA patient population. We estimate that increasing eligibility to receive VA health care services to include priority groups 8e and 8g would increase the number of VA patients by nearly 40 percent. Not coincidentally, the scenarios with the largest potential impact on VA in terms of patient counts are those that address eligibility, access, and patient choices. These scenarios could come about as the result of VA policy or congressional action rather than external policies or trends. Other scenarios, such as the ACA coverage expansion scenario, suggest more-modest effects, with changes in projections of VA patients over time on the order of tens or hundreds of thousands of patients per year, in the context of a base of approximately 6 million patients. Still, the impacts that we describe are potentially important for VA's resource allocation and planning, and for improving access and quality of care.

We considered a range of other potential drivers of change in VA patient projections that were not evaluated as formal scenarios.

Changes to the cost of employer-sponsored insurance: For example, the so-called "Cadillac tax" on high-cost employer-sponsored health plans introduced in ACA will go into effect in 2018

and could affect the non-VA coverage options available to some Veterans. More generally, ACA's employer mandate could drive some small and large firms to change the way that they provide coverage to their employees, or whether they provide coverage at all. Veterans could increasingly rely on VA for care if employers drop coverage or reduce the generosity of coverage over time, or if premiums for employer-sponsored insurance increase significantly over time.

Changes in the generosity of specialty drug coverage: Other trends in commercial insurance could drive Veterans to access more of their care through VA than through other sources. Commercial insurers increasingly place expensive biologic and other specialty prescription drugs on formulary specialty tiers, which are then often tied to significant cost-sharing, including co-insurance rates. Eligible Veterans can avoid paying hundreds or thousands of dollars in cost-sharing for specialty drugs by accessing these drugs through VA. This kind of "wrap around" use of VA increases enrollment and patient counts (because we define a VA patient as a Veteran using any VA health care services, even if it is only prescription drugs), and results in a considerable cost to VA in terms of the purchase and administration cost of the drug, but in the short-term, it introduces few new demands on the VA health care system. However, for Veterans enrolling in VA to receive a single "gateway" service like expensive specialty drugs, their proportion of care may expand over time. Current VA projections on the impact of specific specialty drugs (for example, expensive new hepatitis C treatments) focus on direct drug costs only and not on the impact of changes in specialty drug coverage outside of VA on projections of demand for VA care overall.

Changes in access to mental health services: The evolving mental health landscape is an example of a change that could lower VA patient projections over time. Recent legislative changes have increased non-Veterans' access to and coverage for mental health care. The implementation of the Mental Health Parity and Addiction Equity Act in 2010, combined with the inclusion of mental health coverage as an essential benefit in 2014, has greatly increased the mental health coverage available through private insurance plans. The Office of the Assistant Secretary for Planning and Evaluation in the U.S. Department of Health and Human Services has estimated that this 2010 law, combined with the ACA, will lead to greater mental health and substance abuse treatment coverage for more than 62 million Americans. Additionally, mental health coverage has now been fully phased in to parity in Medicare (wherein cost-sharing for mental health care must be on par with medical and surgical care) in 2014, increasing coverage of these services for 48 million Medicare beneficiaries. Given traditionally high levels of reliance on VA mental health services amid the limited availability of civilian coverage, these large changes may manifest in markedly different trends. In our analyses of MEPS data through 2012, Veterans who have access to employer-provided insurance or Medicare had modest increases in VA mental health spending over time compared with considerable increases for Veterans without other sources of coverage, suggesting that Veterans may be increasingly accessing mental health services outside VA. Given this expansion in the civilian sector and this early evidence of differential responsiveness depending on Veterans' alternative health service coverage statuses, careful attention should be paid to the projected utilization of VA mental health services going forward.

Changes in assistance programs and Veteran income: The Social Security Disability Insurance (SSDI) program provides Medicare coverage and monthly cash benefits to more than 13 million Americans and, according to counts from the 2013 ACS, more than one-third of 1 million Veterans or their households. However, this program is facing impending insolvency, and in the exhaustion of the SSDI Trust Fund, projected by the Congressional Budget Office to occur in the last quarter of 2016, all benefits currently being paid out would be immediately cut by 20 percent in the current-law framework. Because this income is included in household income when determining VA priority groups, such a decline could cause Veterans otherwise ineligible for enrollment to now fall under priority group 8b or 8d income thresholds, as well as reassign currently eligible Veterans to higher priority groups with lower or no co-pays, both of which would directly affect program costs. In our analysis of 2013 ACS data in combination with the priority group classification algorithm described in this section, we found that of the 335,000 Veterans in the 2013 ACS either receiving SSDI benefits themselves or residing in a household with an SSDI beneficiary, 260,000 were eligible for VA health services (among whom slightly more than half [132,000] were VA patients), while 75,000 Veterans had household incomes too high to qualify for enrollment. Although a preliminary analysis suggests that there would be a limited number of newly eligible Veterans given a 20 percent SSDI benefit cut, there is the potential for substantial reshuffling from priority groups 7 and 8a–8d to priority group 5. Additionally, SSDI benefits will continue to fall in every year after 2016 if there is no policy action going forward, increasing the extent to which Veterans are affected. Due to the size of this population and the wide range of shifts that can occur in both the presence and the absence of policy changes, careful attention should be paid to how these shifts will affect Veterans receiving SSDI benefits in the years to come.

7 Conclusions and Recommendations

In this assessment, we estimated the current and future demographic characteristics of Veterans, estimated the current health care needs of Veterans and VA patients, projected future health care needs of the Veteran population, estimated the extent to which Veterans rely on VA for their health care, and considered how future policy changes or trends may affect the population of eligible or enrolled Veterans or the rate at which Veterans rely on VA for health care. In this section, we summarize the findings of these analyses and offer recommendations for consideration as VA plans to meet future needs for health care services.

7.1 Summary of Assessment A Findings

7.1.1 Current and Future Demographic Characteristics

We estimate the total number of Veterans in 2014 to be approximately 21.6 million. Over the 10-year projection horizon, we estimate that this number will decrease by 19 percent, to 17.5 million, by 2024. The most significant population decline will occur in the Ohio River Valley region (the Great Lakes region spanning from western New York through the Midwest), with some marginal increases in population size in parts of the Southeast. The share of female Veterans is expected to grow, and the average age of Veterans will also increase over this period. The largest change in the relative share of service era cohorts is a decrease in pre-Vietnam- and Vietnam-era Veterans and a large increase in the number of Gulf War and, especially, post-9/11 Veterans.

Between 2015 and 2024, the Veteran population is expected to become more geographically concentrated in urban areas, a result that is consistent with expectations about migration of the U.S. population more generally. The proportion of Veterans in both the youngest and oldest age groups is expected to increase over the same period, which will result in more variation in geographic age patterns. Trends in geographic distribution by age are expected to reflect cohort changes where Veterans reside rather than patterns of migration. Overall, the average age of the population is expected to rise slightly. In areas where the proportion of older Veterans is projected to decline over the 2015–2024 period, the cause is likely that insufficient numbers of younger Veterans are moving to these regions over time. On the other hand, areas that will see a larger proportion of older Veterans over time are those where middle-age Veterans currently live and are expected to stay as they age. While Veterans are mobile, our estimates suggest that migration is relatively small and not likely to be a major factor in Veteran demographics.

As mentioned in Section 3, Veterans are half as likely as non-Veterans to live below the poverty line, and they also enjoy higher median incomes. In addition, Veterans are less likely than non-Veterans to be unemployed. Disability status is a strong predictor of unemployment, and the rate of unemployment within the Veteran population varies widely by service era and age. Veterans are also more likely than non-Veterans to have health insurance, in addition to VA benefits, through both the public and private health insurance sectors. In fact, the majority of Veterans enrolled in VA health care have other health insurance options.

Although approximately one in 10 U.S. adults is a Veteran, Veterans account for 16 percent of homeless adults and 13 percent of sheltered homeless adults. Female Veterans are three to four times more likely than non-Veteran women to become homeless. Health conditions are more prevalent in homeless Veterans than they are in homeless non-Veterans, and these rates increase as time spent in homelessness increases. However, despite these concerns, the overall rate of homelessness among Veterans is low and has been declining over time. The U.S. Department of Housing and Urban Development reports that there were approximately 49,933 homeless Veterans in 2014 (less than 0.25 percent of the Veteran population), representing a 33-percent decline in homelessness among Veterans since 2010.

7.1.2 Enrollment in and Reliance on VA Health Care Services

7.1.2.1 Enrollee and Patient Projections

In order to project the number of VA enrollees and patients over the 2015–2024 period, we used a sensitivity analysis approach. We considered three different sets of assumptions, each of which accounts for factors that likely affect Veterans' enrollment decisions and VA use rates. In 2014, there were 9.09 million VA enrollees and 5.87 million VA patients, and by 2024, we project between 9.33 and 10.00 million VA enrollees and between 5.81 and 6.18 million VA patients. The differences in our projections are primarily driven by enrollment and use rates among Veterans who served in Iraq and Afghanistan. In 2009, 6 percent of VA patients deployed in Iraq or Afghanistan, but by 2014, this percentage increased to 12 percent. Assuming this pattern continues, we project that, by 2024, approximately 20 percent of VA patients will be Veterans of deployment in Iraq or Afghanistan.

Our estimates suggest that the Veteran population will shrink by 19 percent between 2015 and 2024. Over the same period, we project that the VA patient population will peak in 2019 and begin to taper off or decline through 2024. The less-pronounced decline in the size of the patient population relative to the Veteran population is related to recent increased enrollment and use of VA health care, particularly among younger Veterans. The rate of use among Veterans under age 35 has increased threefold since 2005. The growth in the younger VA patient population may be related to outreach efforts on the part of VA, streamlined enrollment processes, and enhanced eligibility rules for Veterans of Afghanistan and Iraq. These trends contributed to a significant growth in the total VA patient population between 2000 and 2014, despite a decline in the overall Veteran population. While we estimate that these growth rates will taper off in the near future, the projected declines in the size of the patient population are small relative to the projected declines in the total number of Veterans.

7.1.2.2 Reliance on VA

The goals of our health care needs analysis were to describe and project numbers of people (Veterans overall and VA patients in particular) and prevalence rates of health conditions—but not to estimate demand for or utilization of services. However, because MEPS captures all health care that is received by its respondents—from VA and from other sources—the data provide an opportunity to estimate Veteran reliance on VA. Reliance represents the share of health care services that patients receive from VA compared with other sources, and is

important to VA planners because it can have an effect on demand for VA services. For example, if reliance increases due to rising health care costs in the civilian sector, VA may need to provide more care even if the number of VA patients is unchanged. Because VA's EHCPM also estimates reliance, we were able to generate estimates of reliance on a subset of health care services, which can then be compared with the results of VA's model.

We computed two reliance rates: (1) the share of health care services that VA patients receive from VA and (2) the share of health care services that all Veterans receive from VA, where, by definition, the second rate will be smaller than the first because some Veterans receive none of their health care from VA. Reliance rates for both populations were calculated for prescribed medications, all office visits, inpatient surgery, and specific office visit categories.

Among both VA patients and all Veterans, the highest rate of reliance on VA services is for office-based laboratory services, at 34 percent and 22 percent, respectively. Office-based radiology services rank second, at 32 percent for patients and 20 percent for all Veterans, in terms of reliance. Younger Veterans (and patients) rely on VA for more of their prescription drug, office visit, and inpatient surgical care than do older Veterans (and patients), a result that can likely be explained by differences in other health insurance status. Veterans and patients with lower incomes also rely on VA for both of these services. Living outside of a metropolitan area, being uninsured, and being in relatively poorer health are characteristics that are associated with greater reliance on VA for prescription drug services and office visits.

For many service categories, EHCPM yields different reliance estimates from those calculated in MEPS. For example, EHCPM predicts that 66 percent of prescription drugs are delivered to enrollees through VA, whereas MEPS results suggest lower rates: 30 percent for patients and 16 percent for all Veterans. It is unclear what drives these differences between EHCPM and MEPS, although they may be partially related to differences in methodologies, including (1) the population for whom reliance is estimated (e.g., enrollees or patients), (2) the data used to produce these estimates (e.g., survey, administrative, or commercial), and (3) the extent to which all health care encounters are captured in the data (e.g., based on self-reports or payer information). While we know MEPS has limitations, we have only partial visibility into the strengths and weaknesses of the EHCPM approach. For these reasons, we cannot fully determine why the approaches differ, or speculate about which approach is preferable.

7.1.3 Current and Projected Health Care Needs

Our health care needs analysis compared diagnosed conditions of Veterans and non-Veterans, as well as those of VA patients and Veterans who do not use VA health care.

Without adjusting for demographic differences between Veterans and non-Veterans (for example, Veterans are older and predominately male), we found that the prevalence rates of many diagnosed health conditions are higher in the Veteran population. Veterans are more likely than non-Veterans to be diagnosed with cancer, diabetes, hearing loss, and PTSD. A limitation of our analysis is that we observed only diagnosed conditions rather than true underlying health status. Because Veterans are more likely to be insured than non-Veterans, they may be more likely to receive a diagnosis than their non-Veteran counterparts.

Veterans are also on average older than non-Veterans, and many conditions that we explored in our analysis are more likely to be diagnosed as individuals age. In addition, Veterans are predominantly male (greater than 90 percent), whereas only 40 percent of U.S. non-Veterans are male.[56] Therefore, conditions that are more likely to affect men will naturally have higher unadjusted prevalence rates in the Veteran population. Other characteristics that differ between the two populations may have similar effects on unadjusted rates. To compare health care needs for Veterans with their non-Veteran counterparts, we adjusted our estimates to account for age, sex, race/ethnicity, region of residence, and whether the individual resides in a metropolitan area.

After adjusting for these characteristics, we found that Veterans continue to have higher prevalence rates of most conditions, including mental health conditions. This result is particularly salient for PTSD. Veterans are 13.5 times more likely than non-Veterans to be diagnosed with the condition. Even though fewer than 5 percent of Veterans are diagnosed with PTSD, this condition is even rarer in the non-Veteran population. PTSD and mental health conditions more generally are negatively correlated with income and employment status; higher income and being employed are correlated with lower rates of PTSD and mental health problems. Yet, these Veteran to non-Veteran patterns hold even if we adjust for income and employment status, with Veterans still more likely than non-Veterans to be diagnosed with PTSD and mental health conditions. Unemployed Veterans have particularly high rates of PTSD, both overall and in comparison with unemployed non-Veterans.

Our adjusted estimates showed that Veterans are also more likely than non-Veterans to be diagnosed with chronic conditions, such as diabetes and hypertension. In general, differences between Veterans and non-Veterans become more pronounced with age, although, for mental health conditions, we found the greatest differences at younger ages.

Despite these higher rates of diagnosis among the Veteran population, an analysis of disease burden on daily living suggests that Veterans are less likely than non-Veterans to need help with ADLs, such as bathing and dressing, as well as IADLs, including such chores as housework, buying groceries, and using the phone. Veterans are no more likely than non-Veterans to have multiple co-morbid or co-occurring conditions. We offer a couple of explanations for why Veterans may be more likely to have chronic and other conditions, but less likely to experience difficulties with daily functions. One possibility is that the *types* of health conditions faced by Veterans are not the ones that create daily living challenges, such as memory, personal care, mobility, or work-disabling conditions. Alternatively, because we are unable to control for combat experience using survey data, our ADLs results may reflect better functioning among non-combat Veterans. We also examined adjusted differences in comorbid mental health and estimated that Veterans were approximately three percentage points more likely than non-

---

[56] The entire U.S. population is nearly half male (49 percent), but that includes Veterans, most of whom are male. When the population is divided into Veterans and non-Veterans, data indicate that only 40 percent of non-Veterans are male. In addition, survey data used to generate these percentages exclude individuals in correctional, juvenile, and other institutions, who are most likely male and therefore drive the percentage of non-Veteran males down.

Veterans to have a diagnosed mental health conditions and any of the 29 other conditions we investigated in our health care needs analysis. Veterans were statistically neither more nor less likely than non-Veterans to experience comorbid mental health with any of the 16 Charlson conditions, any ADL limitation, or any IADL limitation.

Next, we examined how the diagnosed health care needs of VA patients differ from Veterans who do not use VA. Unadjusted prevalence rates of most conditions are higher among VA patients than they are among Veterans who do not use VA, with the largest differences exhibited in hypertension, diabetes, GERD, cancer, COPD, and PTSD. Even after controlling for a basic set of demographic variables, VA patients have higher rates of these conditions, although the differences between the two groups' prevalence rates are smaller. PTSD once again stands out as a condition that is much more common in VA patients than non-patients

We investigated whether disease burden was more prominent in VA patients than in Veterans who do not use VA. VA patients were more likely to have a Charlson comorbidity index greater than one and were more likely to have at least one IADL limitation, relative to Veterans who do not use VA. Similarly, VA patients with a mental health diagnosis are more likely than Veterans who do not use VA to also be diagnosed with one of the other health conditions examined in Section 5.

We used VA encounter data to examine rare, service-connected conditions that may uniquely affect Veterans. Among the conditions we considered, the prevalence rate—measured as the percentage of Veterans who receive treatment *from VA* for a particular condition—is highest for substance use disorder at 6.3 percent. Slightly less than 2 percent of Veterans who receive treatment at VA were diagnosed with TBI. Amputation and spinal cord injury were each diagnosed in 0.5 percent of VA patients, and the prevalence rate for burns was 0.1 percent.

We also projected the prevalence of health conditions over the 10-year time horizon, 2015–2024, using MEPS data covering health care received in all sectors, not just from VA. We predict an increase in the prevalence of chronic conditions that affect both Veterans and non-Veterans, such as hypertension, diabetes, and cancer, all of which become more common as an individual ages. Mental health conditions are expected to become slightly more common among Veterans, rising from 19.4 percent in 2015 to 20.7 percent in 2024. The prevalence of PTSD, however, is expected to remain relatively constant at around 3 percent. Like Veterans more generally, the prevalence of diagnosed hypertension, diabetes, and cancer is expected to rise among VA patients. The patterns of mental health and PTSD are also similar for Veterans and VA patients, though the levels and projected increases are higher among patients. The prevalence of diagnosed mental health conditions is expected to increase from 28 percent to 34 percent, and the rate of diagnosed PTSD is projected to grow from 8 percent to 10 percent.

7.1.4 Sensitivity of Projections to Policy Changes

Our estimates of the demographic characteristics of the current and future Veteran population, as well as our analysis of the health care needs of Veterans and VA patients, assumed, implicitly, that the policy arena and other characteristics of the current environment would continue into the future, with the exception of specific data inputs and trends. For example, our analysis accounted for DoD's planned reduction in the size of the active duty military. Our

baseline projections, however, did not account for future policy scenarios that might affect demand for VA health services. In order to test alternative assumptions about the future, we examined five scenarios that represent ways that policy changes may affect the number of eligible or enrolled Veterans or the rate at which Veterans rely on VA for health care.

Three scenarios involve VA policy changes—making priority groups 8e and 8g eligible to enroll in VA, changing presumptive eligibility that would make Veterans who served in Vietnam and who now have hypertension eligible for benefits, and making VA health care services more accessible by removing barriers. In all of these cases, the number of VA enrollees and VA patients would increase. Allowing groups 8e and 8g to enroll could have an enormous effect on the number of VA patients. Opening eligibility to these two groups could result in 4.8 million new enrollees, and more than 2.1 million new VA patients (a 35.1-percent increase in the patient population). Adding hypertension to the list of presumptive eligibility conditions would results in 363,000 new patients, or an increase of 6.4 percent.

Much attention has been paid in the last couple of years to access problems Veterans face in getting care from VA. Among respondents of NSV who report not using VA services, 12.4 percent (1.8 million) report that the barriers to access are a reason for non-use. If these obstacles are addressed, we estimate that up to 235,000 new patients might use VA for some of their health care needs.

The remaining two scenarios consider changes external to VA's control—a hypothetical future conflict and coverage expansion through the ACA.

We considered how the number of total Veterans and VA patients will increase if the U.S. military becomes engaged in a conflict in the next 10 years. Across different levels of combat exposure and policy environments, our results suggest that the number of new eligible Veterans may range from 1.6 to 2.6 million between 2015 and 2024—200,000 to 1.8 million of whom will have combat exposure. In terms of new patients, depending on the assumptions of the conflict scenario, most of our analyses predicts between 500,000 and 925,000 new patients between 2015 and 2024.

The ACA may have opposite effects on enrollment and patient status for VA. On the one hand, some eligible, unenrolled Veterans may enroll with VA to satisfy the ACA's individual mandate, and some of these new enrollees may then choose to use VA for their health care needs. On the other hand, some VA patients may secure other insurance through either ACA's Medicaid expansion or the law's new subsidies for private coverage. These Veterans might then rely on that new insurance option, thereby reducing or eliminating their reliance on VA. We estimate that approximately 307,000 Veterans could enroll with VA as a result of the ACA mandate, and, of those, approximately 74,000 could become patients. Simultaneously, we estimate that 172,000 fewer current patients will rely on VA for health care needs. We estimate a net decrease of 98,000 VA patients in 2016 under the ACA coverage expansion scenario. We also estimate that this decrease will be larger if more states opt to expand Medicaid to cover all low-income adults.

7.2 Limitations

Our analysis has several important limitations. One critical constraint is that the data sets available to conduct the analysis are themselves limited. There has not been a full accounting of the Veteran population since the 2000 Census, and we had to cobble together data from several sources to estimate the total number of U.S. Veterans and their demographic characteristics. Compounding this issue is that available data sources often define Veterans slightly differently. For example, ACS asks about whether the individual ever served on active duty in the U.S. armed forces, reserves, or National Guard. MEPS, in contrast, asks whether the respondent was honorably discharged from active duty in the U.S. Army, Navy, Air Force, Marine Corps, or Coast Guard. The lack of alignment in definitions makes it difficult to directly compare the data, and could in some cases cause us to overestimate the number of eligible Veterans (for example, because Veterans who were other than honorably discharged are not eligible for VA care.)

In addition to the data challenges associated with defining the Veteran population, there are data challenges in understanding Veterans' health care needs. First, VA administrative data do not capture health care utilization across all sectors, including VA-provided and civilian-provided care. While MEPS captures all types of care, the sample of Veterans is small and may not be fully representative of the population. Second, the data sets we analyzed did not address respondents' underlying health status, and could not shed light on undiagnosed conditions or health care needs. Collecting information on undiagnosed health conditions is difficult but not impossible—for example, the National Health and Nutrition Examination Survey combines interviews and physical examination. While access to such data for Veterans could be useful, it would also require a costly and complex data collection process in which respondents participated in health examinations. Additional analyses would be necessary to determine if collecting this type of data for Veterans would be worth the cost.

While a strength of our analysis is that we were able to combine both DoD and VA data to understand the diagnosed health conditions of new Veterans, we were unable to do a person-specific transition analysis between service member and Veteran. That is, the data available to use were not granular enough to allow us to observe individuals' transitions; all comparisons are at an aggregate level. More-granular information would allow for additional refinements, such as better understanding demographic differences in how active duty personnel transition into VA care.

Our analysis focused on projections of Veterans, their health and demographic characteristics, and the number of VA patients that can be expected over time. However, we did not address Veterans' demand for specific types of health care services. Understanding how demand for specific services will evolve in the future would be useful for VA planning purposes. Projecting demand, however, requires even more-detailed data and introduces additional uncertainty because changes in technologies, treatments, and scientific knowledge may influence the type of health care services that Veterans will require.

An additional limitation is that, in some cases, it is very difficult for us to distinguish between age and cohort effects. For example, recent Veterans are more likely to use VA health care than

other Veterans. In part, this reflects a general pattern that young Veterans are more reliant on VA than older Veterans, who are more likely to have access to outside health insurance through an employer or Medicare. However, higher utilization among newer Veterans may also reflect generational changes in utilization patterns that may persist over time. Even with sophisticated statistical methods, it is not always possible to differentiate these two possibilities. To some degree, only time will tell exactly how utilization of VA services will evolve among Afghanistan and Iraq Veterans as they age.

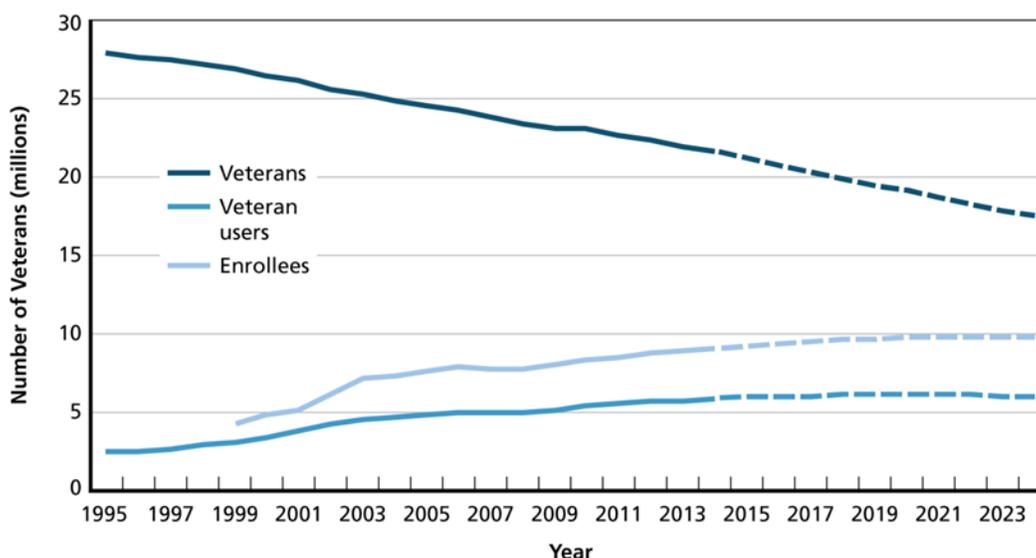
While not a limitation per se, the scenarios that we evaluated in this subsection are speculative and based on assumptions that may diverge from actual conditions in the future.

Finally, we are limited in our ability to compare our analyses with analyses conducted by VA due to limited documentation of existing VA models.

7.3 Recommendations for Consideration

Plan for a Changing Veteran Landscape

For decades, the number of VA enrollees and patients has been increasing, despite a declining Veteran population. Beginning in 2019, we project that the number of VA patients will begin to taper off (Figure 7-1). This is a change that VA has not experienced in several decades, and it suggests that planning for the future may require a new approach. If VA responds to increasing enrollee and patient counts, and to the health care demands that this population requires, by expanding facilities, infrastructure, staffing, and other resources, the result may be a larger-than-needed footprint after 2019, when the population begins to taper off. Rather, VA should begin to plan for a shrinking population now by considering alternative approaches to meeting the needs of its population, such as purchasing care from the civilian sector even while the patient population continues to grow.

Figure 7-1. Trends in the Veteran Population, Enrollment, and Use of VA Care


Improve Tracking of Some Veteran Populations

The U.S. Census is the most comprehensive source of information on Veteran status, but the most recent time these data were collected was 2000. Since then, detailed information on Veterans has been gathered only in ACS, which is known to underrepresent the Veteran population. Therefore, analyses that require full-scale accounting of the U.S. Veteran population rely on data that are 15 years old. While DoD data provide insight into the number of service members who become Veterans when they leave the armed forces, and a number of household surveys capture respondents' Veteran status and include socioeconomic, demographic, and health questions, current efforts to study the Veteran population require analysts to cobble together multiple data sources to augment the 2000 Census. Considering the duration of the post-9/11 conflicts and the number of service members and Veterans who have been exposed to combat during this period, as well as the policies that have been established to address the needs of the Veteran population, the nation is overdue for an update to the Veteran accounting that was possible in the 2000 U.S. Census. Recapturing Veteran information in the U.S. Census will also allow sampling strategies used in smaller surveys to be refined to reflect the current population of Veterans. We recommend re-implementing data collection on the Veteran population in the 2020 Census.

Relatedly, efforts should be taken to closely monitor the nation's newest Veterans, those who served in the post-9/11 era, many of whom have experienced combat. It has been several decades since a generation of Veterans has been exposed to combat in such large proportions and over such a long period of time, and VA and the nation as a whole must prepare to respond to their evolving needs. Policies—such as the five-year enhanced eligibility for VA benefits—are already in place to provide extra coverage to combat Veterans immediately after they separate from the military. While Veterans tend to rely on VA less as they age and gain access to other sources of health care, post-9/11 Veterans may continue to use VA at higher rates because of increased rates of service-connected conditions often related to combat and because enhanced eligibility policies encouraged early use of VA. Closely monitoring this new generation of Veterans will ensure that VA is able to respond rapidly and appropriately to a young population whose needs may be different and evolving in a way that VA has not seen in several decades.

Because current VA encounter data only provide visibility of care that is delivered within VA, little is known about the health care needs of several other groups of Veterans. For instance, many Veterans enroll with VA at some point after separating from the military but then never use VA for care. They represent a population of potential consumers of VA health care under certain future circumstances, which we explore in our scenario analysis. Additional tracking of this non-using enrolled population could be achieved through surveys—including "MEPS for Vets" as described below that address each Veteran's health care needs and where he or she is receiving treatment for these conditions.

VA policy currently prohibits Veterans in priority groups 8e and 8g, comprising higher-income Veterans without disabilities, from newly enrolling. There are no publicly available estimates of the number of Veterans in each of these priority groups. However, using the 2013 ACS, we estimated that there are 78,000 Veterans who meet the criteria for priority group 8e, and 4.7 million Veterans who meet the criteria for priority group 8g; none of these Veterans is currently eligible to enroll for VA health care services. We estimate that if VA were to allow priority group 8e Veterans to enroll, 34,000 new Veterans would become VA patients if they use VA at the

same rate as other priority group 8 Veterans. Because 8g is a much larger population (approximately 4.7 million Veterans), an extension of eligibility rules to include them would have a major impact on VA patient counts, by as many as 2.1 million new patients. Tracking these Veterans, especially for the purposes of being resourced to care for them if a policy change reopens enrollment privileges, is important.

Finally, requirements for eligibility for VA benefits are at least 24 months of military service, concluding with an honorable discharge, and for reservists, a period of activation. If future policies relax these requirements for Veterans who are not currently eligible for benefits, VA might experience an increase in the number of new enrollees and patients. For instance, service members who serve for fewer than 24 months are ineligible to receive VA benefits, but it is possible that someone may deploy to a combat zone before separating under these circumstances. If policy were changed such that the 24-month rule were relaxed if a Veteran had experienced combat, this may also result in an inflow of new VA patients. We did not have data on either of these groups for the analyses in this assessment, so we did not attempt to quantify how many Veterans may be affected by these hypothetical future policy changes.

Anticipate Potential Shifts in the Geographic Distribution of Veterans

Between 2015 and 2024, the geographic distribution of Veterans will experience only moderate shifts, but there are opportunities to improve VA coverage in response to some of the movement, particularly among certain age groups. The Ohio River Valley and upper Midwest are expected to experience declines in the Veteran population, which suggests existing facilities may be consolidated. Regions such as Washington, D.C.; Charlotte, North Carolina; and San Antonio and Austin, Texas, are projected to see growth in the total number of Veterans, but VA has already positioned health services in those areas. Other growth areas in the West, including Montana, Wyoming, and Colorado, do not have VA coverage and may therefore benefit from the installation of telehealth and CBOC services.

Because the overall Veteran population will continue to age over the projection horizon, health services related to aging will be needed everywhere. However, younger Veterans under age 35 are expected to become more concentrated in a number of areas—such as Los Angeles; Dallas; Washington, D.C.; northern New Jersey; northern California; central Washington state; the Midwest; Wyoming; and Utah—thereby creating a need for health care services geared toward young adults in these regions.

Finally, the Veteran population in the Southwest has the most uneven alignment between Veterans and VA health care services. Population growth is expected, including among young Veterans, and the region is already characterized by widely spaced facilities with limited access to alternative VAMCs in close proximity to the patient population. As the demand for services expands, the southwest region presents an opportunity for VA to grow to meet the health care needs of its growing population.

Improve Data Collection Regarding Health Care Utilization

The analyses in this report relied on a variety of data sources, including public use surveys that report whether a respondent is a Veteran, VA medical encounter data, other VA data sources, and DoD MHS claims data. While all of these data sources provided some of the information

that was required for this independent assessment, and together they enabled an analysis of our key questions, none provided a comprehensive overview of Veteran reliance on VA, defined as the share of health care services that VA patients (or Veterans more generally) receive from VA versus other sources.

In Section 4, we used MEPS to estimate Veteran and VA patient reliance on VA. However, our analysis has limitations. First, the number of Veterans and VA patients surveyed in MEPS is small. Second, we were able to define several health care services in these data, but not the full range of services that are delivered or that EHCPM estimates. One way to allow for a more thorough, independent analysis of reliance is to oversample Veterans in MEPS and, if necessary, collect additional information on more-detailed services received through VA and other health care sources. This "MEPS for Vets" could build upon the existing MEPS at a much lower cost than it would require to develop a new survey.

Incorporate Separation Patterns and Health Care Needs of Current Service Members into Projections

In this assessment, we incorporated data on current service members, who will become Veterans in the future, in several of our analyses. Our demographic projection model incorporates counts of service member separations to augment Census 2000 data on Veterans. To estimate Veterans' future health care needs, we acquired data on diagnosed health conditions among service members separating from active duty and who received care through the MHS. Finally, in our scenario analyses, we estimated the number of service members who might separate from active duty and become Veterans in the case of a hypothetical future conflict.

Similar to our demographic projections approach, VetPop2014 uses separation data to account for new Veterans as they leave the military. VetPop2014 uses information on age, sex, and active/reserve status. Our approach uses that same information but also includes service branch and race/ethnicity, both of which may be important factors in accurately estimating Veteran counts and health care needs of the Veteran population.

Incorporating service branch allows the model to capture variation in sex across the services— which ranges from 7 percent female in the Marine Corps to 19 percent female in the Air Force—and, consequently, estimates of the sex composition of the Veteran population. Additionally, if the model accounts for an individual's branch of service, projections of future Veteran counts can better handle changes in end-strength and differences in separation patterns (years of service, retirement rates, etc.), which vary considerably by service.

Both the RAND approach to modeling Veteran demographic characteristics and VetPop2014 predict greater race/ethnicity heterogeneity in future Veteran populations, with VetPop2014 predicting greater minority growth than RAND predicts. This difference may be a reflection of different approaches to controlling for minority mortality; the RAND model allows for race/ethnicity-specific mortality, and VetPop2014 does not. In addition, to the extent that there are differences in some health conditions by race/ethnicity, including this characteristic in models of health care projections will lead to more accuracy in predictions.

We estimate that future conflicts could lead to large increases in the number of Veterans who might seek care through VA, as well as large increases in the number of Veterans with combat exposure. For example, in some scenarios, we found that a conflict similar to those in Afghanistan and Iraq could lead to more than 2 million new Veterans and more than 500,000 new patients. Accounting for future conflicts is inherently uncertain. However, developing tools to estimate how conflicts could affect demand for VA services could make it easier for VA planners to respond in the event that a conflict scenario emerges. With an existing model in place, parameters and assumptions could be changed as policy details and information become available.

At present, VA does not have access to DoD MHS encounter data. For this study, we utilized MHS data from 2008–2014 to explore whether current service members (future Veterans) have different health care needs from current Veterans. We estimate that current service members are much more likely than current Veterans to have a diagnosed musculoskeletal condition at the time of separation from service. On the other hand, the rates of PTSD and mental health are higher in the existing Veteran population than they are among separating service members. This result may reflect a disincentive to present with mental health conditions while serving in the military. To the extent that individuals who separate from the military and become Veterans over our 2015–2024 projection window have different health care needs from the patients currently being served by VA, the addition of MHS data may be a crucial input to projecting the needs that VA must meet in the future.

Despite the important addition of MHS data to the analyses in this assessment, time constraints prevented us from conducting a longitudinal analysis of the transition from service member to Veteran. Ideally, the analysis would link medical records at the individual level to determine which health conditions that were diagnosed during an individual's time in service carry over to VA for follow-up and continued treatment. This analysis is feasible with the data used in this assessment, and we therefore recommend that it be undertaken to improve estimates of the types of health conditions and numbers of patients that VA should be prepared to treat as service members separate from the military.

Develop Analytic Framework to Perform Scenario Testing

Our analysis of five future scenarios highlights the importance of developing methods and models that can respond quickly and agilely to policy changes. While some of the policy changes we considered resulted in modest changes in the number of new Veterans and new VA patients, others estimated as many as hundreds of thousands of new Veterans and patients. VA OACT has a Veteran Healthcare Scenario Model that is able to estimate, for instance, how changes in demographic characteristics or economic conditions (such as employment or income) may affect demand for VA services and related costs. Expanding this model to include such events as future conflicts, changes in the civilian health sector, unanticipated changes in perceptions about health care quality, and groundbreaking new technologies, to name a few, will enable VA to address the types of uncertainties that current models may not address. Having methods in place to estimate the effects of these types of changes on Veteran demand for health care services will improve VA's efforts to meet the health care needs of its patient population.

7.4 Overall Assessment A Conclusions

Although the number of Veterans is expected to decline over the next decade, the number of Veterans seeking health care services through VA is expected to increase until its peak in 2019 and taper off or even decrease thereafter. These continued increases in VA utilization reflect changes in VA policies, such as outreach to enroll new patients and expansions to presumptive eligibility criteria, and may also reflect external trends, such as increasing costs in the private health insurance sector. We also estimate that VA patients will become somewhat older and sicker over time, a pattern that could increase demand for VA services despite the relative stability in the size of the patient population.

Reflecting VA patients' older age, the diagnosed prevalence of common chronic conditions (e.g., diabetes, cancer) is two to three times higher among Veterans than among non-Veterans. Thirty-three percent of all patients seen at VA have a mental health condition, and 8 percent have PTSD. When combined with the otherwise rare conditions related to combat— amputation, TBI, blindness, and severe burns—and the vulnerable circumstances of some patients, VA handles a patient mix that is uniquely different from what community providers are used to.

However, demand for VA health care services is sensitive to the size and demographics of the VA population, Veterans' underlying health conditions, changes in eligibility and access, and shifts in Veterans' reliance on VA. Limitations with current VA data systems make it difficult to fully account for all of these issues when estimating the future needs of the patient population. There has not been a full accounting of all U.S. Veterans since the 2000 Census. As a result, it is difficult to be fully confident in estimates of even the size of the Veteran population, let alone their mix of demographic characteristics. Current VA surveys provide limited information on Veterans' total health care utilization and health care needs, particularly for Veterans who do not currently access health care at VA. Yet, understanding the needs of patients who do not use VA care is critical for projecting how the patient mix might shift due to policy changes, such as eligibility expansions.

Even among VA patients who regularly use health care, current VA data sources inadequately capture patients' total health care utilization. Both our analysis using MEPS and VA's own analysis using EHCPM suggest that many VA patients rely only partially on VA for their health care services. Yet reliance is sensitive to factors that are both inside and outside of VA's control, including perceptions about the quality of care available at VA facilities, wait times, and the cost of private-sector care. Better data to understand the full profile of Veterans' health care needs could help VA plan for changes in demand that could arise due to these internal and external factors.

Appendix A   Current and Projected Demographic Trends in the Veteran Population

A.1   Data and Analytic Approach

A.1.1   Definition

A.1.1.1   Veterans

For the population projection exercise the team defines Veterans consistently with ACS, which defines Veterans as having "ever served on active duty in the U.S. Armed Forces, military Reserves or National Guard. Active duty does not include training for the Reserves or National Guard, but does include activation, for example, for the Persian Gulf War." Once an individual has ceased to serve on active duty in any of these capacities, they are considered Veterans for the purposes of the projections. Note that the team does not have information on length of service (only eras of active duty), or on status of discharge. Thus, not all Veterans in the projection exercise may qualify for VA services. For example, Veterans who served less than two years, or Veterans with "bad paper" discharges (dishonorable discharges, other-than-honorable and bad conduct discharges) are all ineligible for VA services, but are included in the projection exercise. No federal agency publishes the numbers of "bad paper" discharges, but a range of sources suggests that dishonorable discharges represent 1 percent and other bad paper discharges are an additional 3 percent of all separations (Carter, 2013; Philipps, 2013; Wicker, 1991). Section 4 derives VA users from the overall population projection estimates.

	PUMA

Race/ethnicity is coded as: non-Hispanic white, non-Hispanic black, Hispanic, non-Hispanic Asian, non-Hispanic other. In cases where individuals report multiple race categories they are coded as "non-Hispanic other" as limited by the data.

The analysis defines seven service eras: pre-1950, Korean War (July 1950–January 1955), pre-Vietnam peace era (February 1955–July 1964), Vietnam era (August 1964–April 1975), post-Vietnam peace era (May 1975–July 1990), Gulf War era (August 1990–August 2001), post-9/11 (September 2001 or later). Individuals are grouped into the most recent active duty wartime era they served in (if they report multiple periods of service), or if they only served during peace time, they are grouped into their most recent peacetime era.

For units of geography the team uses PUMA: Public Use Microdata Area. Since 2005, the ACS has collected information based on PUMAs. PUMAs are geographic units used by the U.S. Census Bureau. The state governments drew PUMA boundaries for the 2000 Census to allow reporting of detailed data for all areas. There were a total of 2,071 PUMAs in the 2000 Census and 2,351 in the 2013 ACS. Because PUMA boundaries changed over time, the team generated geographical areas compatible across the surveys, taking the 2013 ACS boundaries as the baseline. These comparable areas are used throughout the population projection exercise. Note

that rural and urban areas may be simultaneously contained within a single PUMA (they are not necessarily 100 percent rural or 100 percent urban). Our use of PUMAs is partly driven by necessity (they are the smallest geographic unit available in the ACS data we rely on), but PUMAs also provide some benefits to our modeling approach. PUMAs are designed to contain populations of 100,000, which ensures that each PUMA contains population sizes amenable to even relatively small cell sizes (older Asian female Veterans, for example). Large cities, such as Los Angeles, contain several PUMAs. In areas with sparser populations, a single PUMA may contain multiple counties. In contrast, geographic units, such as county, are not based on population size; as of 2013 there were 3,144 counties and county equivalents in the U.S., and it is likely that many counties would have Veteran populations too sparse to model reliably. However, the use of PUMA does present some special challenges for mapping purposes. Since PUMAs are groups of 100,000 people (in practice, they can sometimes reach upwards of 150,000), they can be geographically small in dense urban areas. In fact, 25 percent of all PUMAs fall within a 40-mile radius of just 10 cities. For example, Figure A-1 depicts the PUMA that contain the population of Los Angeles, CA. There are 54 PUMAs within 20 miles of downtown LA—most of which would be near invisible on a page-size map of the United States. As such, rather than shading these maps by the population *inside* each PUMA, we shade them according to the total population *near* each PUMA. Specifically, we shade each PUMA based on the total population of the PUMA within 40 miles of each PUMA center.

Figure A-1. PUMA in Los Angeles CA

A.1.2 Data Sources

2000 Census: The 2000 Census collected information about the 115.9 million housing units and 281.4 million people in the United States on April 1, 2000. A 5-percent sample of people and housing units received a more detailed long form survey that contained questions including Veteran status and periods of service. As a starting point, the team used the 5-percent sample 2000 Census data to assess the baseline Veteran population in 2000. The 2010 Census did not include a long form, and did not collect information on Veteran status. The 2010 Census short form included only basic demographic questions (e.g., name, relationship with head of

household, sex, age, Hispanic origin, race) and household information (e.g., number of people in the household, whether the home is owned or rented). The 2000 Census long form asked detailed demographic and household questions, including Veteran status and time that person served on active duty in the U.S. Armed Forces. As of the 2010 Census, detailed sociodemographic and other information is collected in the ACS, rather than the Census.

Active Duty Master and Loss Files 2000–2014: The Active Duty Master File provides an inventory of all individuals on active duty (excluding reservists on active duty for training) for the Army, Navy, Marine Corps, Air Force, Coast Guard, Public Health Service, and National Oceanic and Atmospheric Administration Commissioned Corps at a point in time. Relevant personal data elements include date of birth, sex, race, and ethnic group. Relevant military data elements include months of service and basic active service date, as well as anticipated service contract end date. The Active Duty Military Personnel Transaction File contains a transaction record for every individual entrance, separation, or reenlistment in the Army, Navy, Air Force, Marine Corps, and Coast Guard within a specific time frame. The active duty loss files are subsets of the Master/Transaction file. The team used these data to supplement the 2000 Census counts for April 2000–December 2014. Each separation or "loss" indicates an incoming Veteran to the civilian population.

Work Experience (WEX) and Contingency Tracking System (CTS) Files 2000–2014: The WEX contains a longitudinal record for each individual who has served in the active or reserve forces since September 1990. For those individuals, the WEX includes information on service back to 1975. The file is organized by "transactions"; in other words, a new record is generated whenever there is a change in the key variables—service/component/reserve category, pay grade, occupation (primary, secondary, or duty), and unit identification code. The WEX is built from information in DMDC's Active Duty Master Personnel Edit File, equivalent reserve files, and the underlying service files. Information on actual deployment can be found in a sequence of "contingency files." The most recent of them is the Contingency Tracking System file. It contains one record for every activation or deployment in support of the conflicts in Iraq and Afghanistan. Using the WEX and CTS Files enables the team to identify Veterans who have served in the Reserves or National Guard and who were activated at some point and add them to the incoming Veteran population each year. Note that the CTS file will not identify Reserves or National Guard who were activated for other conflicts, such as Bosnia, for example, and the team acknowledges that the analysis will slightly underestimate the Reserve/National Guard Veteran population.

2005–2009 and 2009–2013 ACS 5-year estimates: ACS is an ongoing mandatory survey conducted by the U.S. Census Bureau that collects data each year to bridge intercensal periods and provide detailed information about the population, including Veteran status. The ACS also includes information on current location, and location in the previous year. The analysis uses the ACS to determine Veteran geographic distribution and migration patterns. It was not possible to use the ACS to accurately measure the number of Veterans in the population; the ACS is generally acknowledged to undercount Veterans, though it is assumed to accurately capture the distribution of Veteran characteristics (age, sex, race/ethnicity, service cohort, location). For example, the 2013 ACS estimates of total Veteran population are roughly equivalent to our own estimates of the number of Veterans observed in the 2000 Census who

are estimated to still be living in 2013—that is, the ACS estimates effectively undercount by the number of new Veterans who entered the population from 2000–2013. For this reason, the team produced a set of population projections using a combination of Census 2000 data, Department of Defense data, and ACS data. More specifically, the team used the 2005–2009 and 2009–2013 ACS 5-year estimates available through the American FactFinder website (U.S. Census Bureau, undated a). ACS prior to 2005 do not have information about residence in previous year, which is necessary for migration estimates.

Since 2005, the ACS has collected information on PUMAs of residence one year before the survey. PUMAs are geographic units used by the U.S. Census Bureau. The state governments drew PUMA boundaries for the 2000 Census to allow reporting of detailed data for all areas. There were a total of 2,071 PUMAs in the 2000 Census and 2,351 in the 2013 ACS. Because PUMA boundaries changed over time, the team generated geographical areas compatible across the surveys, taking the 2013 ACS boundaries as the baseline. These comparable areas are used throughout the population projection exercise. Note that rural and urban areas may be simultaneously contained within a single PUMA (they are not necessarily 100-percent rural or 100-percent urban).

A.1.3   Population Projection

The projection is estimated using a cohort component approach, a standard demographic method of projecting populations based on births and deaths over time (Preston, Heuveline, & Guillot, 2001). "Births" in this application of the model are new Veterans. Once the overall national projection has been estimated, the analysis then considers Veteran location and migration through the period. Broadly, the team begins with a comprehensive count of Veterans from the 2000 Demographic Census. The next step is to add observed new Veterans each year through 2014 using Department of Defense data, and apply annual age/sex/race-ethnicity specific mortality rates to everyone from 2000–2024. Once the total 2014 population is calculated, the analysis distributes the Veteran population geographically according to observed Veteran data (along a variety of characteristics). The team estimated annual Veteran migration, based on observed Veteran migratory movements, and applied those migration rates to the estimated 2014 population to derive the final 2014 population and distribution. The team then applied the derived 2014 geographic distribution to the 2015 population estimates, and applied migration adjustments to derive the 2015 population distribution. This process continues through 2024. Projections are calculated using the U.S. Census Bureau's Rural and Urban Projection software (See U.S. Census Bureau, undated b).

A.1.3.1   National Projection

The national population projection consists of two main components: baseline Veteran population (at 2000) and projected new Veterans (through 2024).

1. The analysis begins with a well-measured historical baseline Veteran population and adds the number of new Veterans entering the civilian population each year afterward.

2. From the initial year that the Veteran population is assessed, the baseline and incoming Veteran population is progressed through a cohort component projection model in

---

which age-sex-race/ethnicity groups are subjected to age-sex-race/ethnicity specific mortality throughout the projection period (until 2024).[57]

3. Once the total Veteran population is projected through 2024, the team estimates location and migration of Veterans each year throughout the period based on observed and projected trends.

Projections are produced separately for each service era, and combined for national totals.

A.1.3.2   New Veterans

"Births" in the population projection are assessed using data containing a census of observed transitions to Veteran status, and are extrapolated for future periods. The majority of new Veterans 2000–2014 are measured using the Active Duty Master and Loss Files. We supplement this with the WEX and CTS Files to identify Reserves and National Guard who have been activated at some point (2000–2014). For the 2015–2024 period, we estimate the number of new Veterans each year using transition probabilities based on age, sex, race/ethnicity, and branch of service based on total force size derived from WEX. We also assume downsizing of the Armed Forces following announcements by the Army (Tan, 2015) and other information,[58] with a total active duty force of 1.25 million by 2018 (89 percent of 2010). Specifically, by 2018 we assume an Army of 445,000 (79 percent if 2010), Air Force 311,000 (96 percent of 2010), Navy 311,000 (97 percent of 2010), and Marines 186,000 (93 percent of 2010). We further assume that there will be no significant future conflicts during the projection period, which also impacts the number of Reserves and National Guard who will be activated during the period.

A.1.3.3   Mortality Rates

Mortality rates are based on a combination of mortality rates published by the Centers for Disease Control, and mortality rates obtained from the VA OACT. OACT estimates 2014 Veteran population mortality using a variety of administrative data, IRS data, and Social Security Administration data. The Veteran-specific rates are available by sex, but not race/ethnicity. Our analysis used the most recent (2011) CDC rates to derive race/ethnicity specific mortality rates that reflect OACT rates overall, proportionately distributing mortality rates across sex-race/ethnicity groups proportionate to differences observed in the national population. This approach is summarized below:

1. Calculate the proportion of Veterans in each age group for each race/ethnicity, e.g., for ages 20-24.

2. Multiply the proportion of Veterans in each age-race/ethnicity cell by the national mortality rate (deaths per 100,000) for that cell. This would be the death rates of Veterans if they had the same rates as civilians in each age-race/ethnicity cell.

---

[57] Note that projections begin at 17; individuals may join the Armed Forces with parental consent at age 17.

[58] Personal communication from Air Force Enterprise Readiness Analysis Division (HQ USAF / A1PF) via email, September 9, 2014.

3. Calculate the ratio of overall Veteran mortality rate to the rate if Veterans had the same rates as civilians to get the proportional difference in rates.

4. Multiply the civilian race/ethnicity rates by this difference in rates at each age. This gives us the same mortality rates as the VetPop2014 model, but spread proportionately through the race/ethnicity groups based on civilian rates. It does assume that the inflation/deflation factor at each age is the same for each race/ethnicity.

A.1.4   Baseline Geographic Distribution, 2005–2024

While the ACS undercounts Veterans, the analysis assumes that it accurately captures Veterans' geographic distribution. The analysis applies Veteran geographic distribution (by five-year age group, sex, race/ethnicity, service cohort, and PUMA) from the 2005–2009 and 2009–2013 ACS five-year estimates to the national Veteran populations for 2005–2024 in order to assess initial geographic distribution. 2005–2009 ACS 5-year estimates were used to distribute 2005–2008 national population estimates. There are no multi-year ACS estimates for 2004–2008 or 2005–2008 periods. 2009–2013 ACS five-year estimates were used to distribute 2009–2013 national population estimates and 2014–2024 national population projections.

A.1.5   Migration, 2014–2024

Next the team applies migration to the initial 2014–2024 distributions, as outlined below:

- **Number of migrants (numerator of rates):** Calculate number of migrants by five-year age group, sex, race/ethnicity, service cohort, PUMA, and PUMA in previous year using 2009–2013 ACS.

- **Population of PUMA of origin at the beginning of the time interval (denominator of out-migration rates):** Calculate number of Veterans by five-year age group, sex, race/ethnicity, service cohort, and PUMA in previous year using 2009–2013 ACS. These data are merged to the number of migrants file.

- **Population of PUMA of destination at the end of the time interval (denominator of in-migration rates):** Calculate number of Veterans by five-year age group, sex, race/ethnicity, service cohort, and PUMA using 2009–2013 ACS. These data are merged to the number of migrants file.

- **Convert groups of PUMA in previous year to the PUMA level:** Some PUMAs in previous year are combined in groups of PUMAs in ACS for confidentiality reasons. The team converts groups of PUMAs back to the PUMA level by disaggregating the number of migrants and population at the beginning of the period. This distribution is performed based on the population at the end of the period as a weight for each combination of five-year age group, sex, race/ethnicity, service cohort, PUMA, and group of PUMA in previous year. The files with relationship between PUMAs of migration and PUMAs are available in the Integrated Public Use Microdata Series (IPUMS-USA) website (Integrated Public Use Microdata Series, undated).

- **Convert 2000 PUMAs into 2010 PUMAs:** The 2009–2011 PUMA codes are based on the 2000 Demographic Census classification. We convert these codes into the 2010

Demographic Census classification, based on a geographic correspondence engine developed by the Missouri Census Data Center (2012). This conversion is applied to both the PUMA of current residence and the PUMA in previous year (after the conversion procedure from the topic above). The 2012–2013 PUMA codes are already available in the 2010 Demographic Census classification.

- **Append 2009–2011 and 2012–2013 data and add distance:** The team appends back 2009–2011 and 2012–2013 data, after the 2000–2010 PUMA conversion. Information on distance between PUMAs is estimated based on shapefiles available in the Census Bureau website (U.S. Census Bureau, undated c, undated d). Distance is merged to the 2009–2013 data with migration information.

- **In-Migration rates:** Calculate in-migration rates of Veterans by five-year age group, sex, race/ethnicity, service cohort, PUMA, and PUMA in previous year using 2009–2013 ACS. The denominator of these rates is the population of PUMA of destination at the end of the time interval. The team divided the estimated rates by five to originate annual migration rates, because data relates to 2009–2013.

- **Out-Migration rates:** Calculate out-migration rates of Veterans by five-year age group, sex, race/ethnicity, service cohort, PUMA, and PUMA in previous year using 2009–2013 ACS. The denominator of these rates is the population of PUMA of origin at the beginning of the time interval. The team divided the estimated rates by five to originate annual migration rates, because data relates to 2009–2013.

- **Future in- and out-migration rates (gravity models):** The team estimates migration rates with Zero-inflated Poisson regression models, based on 2009–2013 ACS, and apply these rates to the 2014–2024 period. These models are appropriate when the count dependent variable has a high incidence of zeros. For instance, out of 2,909,616 cells in the in-migration model, 2,133,534 have zero migrants (73 percent) and 776,082 have non-zero observations (27 percent). This approach predicts in- and out-migrants as a function of age, sex, race/ethnicity, service cohort, and squared distance, using population at risk as exposure. For in-migration, population at risk is located in the PUMA of destination at the end of the time interval, while population in the PUMA of origin at the beginning of the time interval is used as a control variable. For out-migration, population at risk is located in the PUMA of origin at the beginning of the time interval, while population in the PUMA of destination at the end of the time interval is used as a control variable. Regression coefficients from this model are used to predict in- and out-migration rates for 2014–2024 by applying coefficients to projected Veteran populations. In effect, the analysis assumes that age, sex, race/ethnicity, and service cohort migration patterns remain constant over the next ten years. Regression models do not include year. Models that included year as a predictor (to capture time trends in migration) indicated that there were not significant time trends: the year effect was orders of magnitude smaller than other predictors and did not contribute meaningfully to predicted migration trends. More details about these gravity models are presented below.

- **Number of in- and out-migrants:** The analysis applies the predicted rates from the Zero-inflated Poisson regression models to the initial 2014 population projection to obtain the

number of in- and out-migrants in 2014 for each five-year age group, sex, race/ethnicity, service cohort, PUMA, and PUMA in previous year. Then the team collapses information on PUMA in previous year, in order to get the number of in- and out-migrants for each five-year age group, sex, race/ethnicity, service cohort, and PUMA.

- **Adjustment of the number of in-migrants:** The team adjusts the number of in-migrants in each cell based on the overall count of in-migrants and out-migrants in a specific year. More specifically, the adjusted number of in-migrants equals the original number of in-migrants, multiplied by the overall sum of out-migrants in 2014, divided by the overall sum of in-migrants in 2014. This procedure assures that overall net migration in 2014 equals to zero. The assumption behind this adjustment is that out-migration counts are more accurate than in-migration counts. Out-migration cells were estimated based on residence in a previous year, which is a group of PUMAs. The team allocates both the counts of migrants and the population of origin at the beginning of the time interval into the PUMAs within the group of PUMAs. This approach gives a higher chance of all cells having migrants, because the distribution is based on the population of Veterans in the area of destination at the end of the time interval, as described above. In-migration rates were estimated with information already at the PUMA level, which might generate more cells with small counts and affect the overall number of in-migrants.

- **Net migration:** The team subtracted adjusted in-migrants by out-migrants for each five-year age group, sex, race/ethnicity, service cohort, and PUMA cell and applied this net migration to the initial 2014 population, in order to get the final 2014 population.

- **Weight calibration of counts of Veterans:** The team performs a final adjustment of the counts of Veterans in all cells with a weight calibration procedure known as iterative proportional fitting (raking) of complex survey weights, through the ipfraking package in Stata. This procedure ensures that marginal counts of Veterans by five-year age group, sex, race/ethnicity, and service cohort at the PUMA level equal the national population projection in each year.

The analysis iterates through this process for subsequent years; i.e., use the final 2014 distribution (population after migration) as the baseline for the 2015 national population projection. The table below summarizes the overall counts of Veterans by projected year, number of in-migrants, adjusted in-migrants, out-migrants, and net migration. The final three columns give an idea of the migration rates. As discussed above, the team utilized out-migration rates as the standard, which decrease from 2.97 percent in 2014 to 1.61 percent in 2024 and is consistent with lower mobility through time within the national territory.

Table A-2. Counts of Veterans and Migration Variables, 2014–2024

Year	Veterans	In-migrants	Adjusted In-migrants	Out-migrants	Net Migration	In-Migration Rate (%)	Adjusted In-Migration Rate (%)	Out-Migration Rate (%)
2014	21,579,290	553,963	641,122	641,122	0.0	2.57	2.97	2.97
2015	21,179,305	553,188	612,482	612,482	0.0	2.61	2.89	2.89
2016	20,763,195	545,726	576,489	576,489	0.0	2.63	2.78	2.78
2017	20,346,285	533,323	537,150	537,150	0.0	2.62	2.64	2.64
2018	19,928,403	518,292	495,146	495,146	0.0	2.60	2.48	2.48

A.1.5.1   Gravity Models

As described above, gravity models were estimated with Zero-inflated Poisson regression models. Gravity models estimate migration rates based on population in the area of origin (at the beginning of the period), population in the area of destination (at the end of the period), distance between areas, and other control variables (age, sex, race/ethnicity, and service cohort). The implementation of gravity models is consistent with the study of internal migration determinants, which dates back to classical economic development theory, where migration is considered to be a mechanism that establishes regional spatial-economic equilibrium (Ravenstein, 1885, 1889). Migrants move from low income to high-income areas and from densely to sparsely populated areas. Population streams are expected to occur between the poorest and wealthiest places and countries. Migration decisions are determined by "push" and "pull" factors in areas of origin and destination. Intervening obstacles (such as distance, physical barriers, immigration laws), as well as personal factors also influence migration flows (de Haas, 2007, 2009; Greenwood, Hunt, Rickman, & Treyz, 1991; Lee, 1966; McDowell & de Haan, 1997; Passaris, 1989). Economic, environmental, and demographic factors are assumed to drive migrants away from their places of origin and attract them to new places of destination.

Based on the regional equilibrium framework, distance is expected to play an intervening role on the levels of population flows. Previous studies took distances between areas into account by utilizing gravity models to estimate migration (Head, 2000; Lowry, 1966; Pöyhönen, 1963; Tinbergen, 1962). Gravity models address the distance between areas, as well as the changing population in the areas over time. The idea behind these models is to use distance between areas and population trends as instrumental variables to estimate the level of migration, before

analyzing the migration rates. Gravity models consider the population in the area of origin (at the beginning of the period), the population in the area of destination (at the end of the period), distance between areas, and the proportion of migrants already living in a specific area (dependent variable). Distance is constant over time, but the population at the beginning and end of the period in each area has varying out- and in-migration trends over time.

Zero-inflated Poisson statistical regressions can generate gravity models for inter-regional migration flows, with a dependent variable measured in discrete units (integer counts of migrants) and a discrete probability distribution (Stillwell, 2009). These models are appropriate for this analysis, because they do not maintain error variances as constant for the different sizes of estimated flows, as is the case of "log-normal" models. In the case of migration flows between PUMAs, the model is also recommended because there are a significant number of smaller flows among the areas, as well as a small number of larger migration flows. The Poisson regression equation is:

$M_{ij} = b_0 + b_1 * P_i + b_2 * P_j + b_3 * d_{ij} + \varepsilon_{ij}$

where M_{ij} represents migrants at the end of the period between areas of origin (i) and destination (j); b_0 is the constant; b_1 is the regression coefficient associated with the population in the area of origin at the beginning of the period (P_i); b_2 is the coefficient associated with the population in the area of destination at the end of the period (P_j); b_3 is related to the distance between PUMAs (d_{ij}); and ε_{ij} is the random error term associated with all pairs of PUMAs.

In order to generate these flows, it is necessary to use migration information that indicates the location of residence at a specific previous moment. Information about the PUMA of previous residence (where the person was living one year before the survey) is included in the ACS since 2005. This migration information allows the estimation of: (1) the population at the beginning of the period by age group, sex, race/ethnicity, service cohort, and PUMA (P_i); (2) the population at the end of the period by age group, sex, race/ethnicity, service cohort, and PUMA (P_j); and (3) migrants at the end of the period by age group, sex, race/ethnicity, service cohort, and PUMA of both origin and destination (M_{ij}). This study utilized a matrix of distances between all PUMA centroids, in order to estimate the d_{ij} component of the Poisson regression equation. The cells with no migration flows or no population are replaced by zero in the regression. As a way to control for the high prevalence of cells with zero counts of migrants (dependent variable), a dummy variable indicates whether the cell has zero migrants within the "inflate" option in the Zero-inflated Poisson model.

The results from Zero-inflated Poisson regression models are illustrated in the following table. The first model deals with in-migration, in which population in PUMA of destination at the end of the period is taken as the exposure variable. The model about out-migration utilizes population in PUMA of origin at the beginning of the period as the exposure variable. The general trends of variables are similar between these models and can be better visualized in the figures below. Men have lower chances to migrate, compared to women. On one hand, Veterans in older service cohorts are less likely to migrate, compared to those in 9/11 Era. On the other hand, older Veterans are more likely to migrate, compared to younger Veterans (25-29 age group), specially starting at the 70-74 age group. These two results (service cohort and age) counterbalance each other, since Veterans in older service cohorts (less likely to migrate)

are older in age (more likely to migrate). All race/ethnicity groups are more likely to migrate than Whites. As expected, longer distances between PUMAs have negative impacts on the likelihood of migrating. This information was included as squared distance in order to make the variable more spread throughout the national territory, as well as to be consistent with gravity models. For the in-migration model, population in origin at the beginning of the period has a positive effect on migration, as we would expect of more populated areas sending more migrants. For the out-migration model, population in destination at the end of the period has a negative effect on migration, which is contrary to the original hypothesis, but this coefficient is not statistically significant.

A.1.6   Spatial Regression Models

The team used spatial regression models to examine how growth and movement in the Veteran population is related to the location of VA facilities. These models follow the standard linear modeling format except for two cases.

First, observations are weighted so that all observations of approximately the same location have weights that sum to one. For example, there are 19 PUMAs within a 10-mile radius of downtown Chicago. Each PUMA could be given a weight of 1/19th to indicate that all cases are observed Veterans located near the same set of VA facilities. The weighting procedure used here follows this same principle, but without using a hard cut-off. Instead, each observation receives a weight of:

$$\frac{\sum_i 2^{-D_{ij}/k}}{\sum_j \sum_i 2^{-D_{ij}/k}},$$

where D is a matrix of distances between observations i and j. K is a scaling constant that indicates roughly what distance i and j are far enough away that the location of j only counts as 50 percent the same as the location of i. This weighting allows observations to be scored along a continuum from "same location" to "different location" instead of using a hard cut-off.

Second, the population/net migration of each PUMA is predicted using the distance between its center and the nearest VA facility or other geographic feature. When the resulting coefficients are negative, it indicates that distance from a facility corresponds to smaller populations, i.e., more people tend to locate close to facilities. For estimation purposes, these distances are logged, because the effects of distance on behavior are known to be nonlinear. For example, the difference between 10mi and 20mi makes a significant impact on population behavior, but the difference between 210mi and 220mi has relatively little impact—both are about equally far away.

A.1.6.1   Spatial Regression Models of Migration in Relation to VA Facilities

Table A-4. Migration in 2014 as a Function of VA Facilities

	Adjusted Prevalence (Std. Errors)				
	Model 1	**Model 2**	**Model 3**	**Model 4**	**Model 5**
Covariate					
VAMC			59.28	53.71	52.59
			(5.75)	(5.94)	(6.74)
CBOC		64.22		39.33	37.85
		(10.56)		(10.74)	(11.17)
City 2million +					2.29
					(6.11)
South West					3.72
					(4.99)

	Adjusted Prevalence (Std. Errors)				
	Model 1	Model 2	Model 3	Model 4	Model 5
Intercept	79.78	-132.59	-156.40	-264.25	-289.74
	(4.55)	(64.22)	(23.35)	(37.54)	(48.47)
SOURCE: RAND analysis of VA, DoD, and Census data.					
NOTES: Results in Table A-4 indicate that overall, Veterans tend to move farther away from VAMC and CBOC VA facilities – not closer. Distances to VAMC and CBOC have significant positive associations with net migration, indicating that Veterans are moving to PUMAs that are farther from facilities.					

A.1.7   Comparison to the VetPop2014 Model

Two primary public sources of information regarding the complete current and projected Veteran population are the ACS, conducted by the U.S. Census, and the VetPop2014 model, produced by VA. According to the 2013 ACS there were 19.6 million Veterans[59]—which is somewhat below RAND's estimate of 21.9 million for the same time point. In contrast, the 2014 estimates from the VetPop2014 and RAND models are quite similar: 21.9 million and 21.6 million, respectively. The VetPop2014 model was developed by OACT for Veteran population projections from 2014 to 2043. The model provides Veteran counts by age, sex, service era, and race/ethnicity at the county level.

VetPop2014 is the culmination of years of work and refinement by OACT. VetPop2014 represents the seventh iteration of the OACT Veteran Population Projection Model (the previous iteration was developed in 2011). Here we highlight ways in which our approach differs methodologically from VetPop2014 and how our projection results differ. Documentation for the VetPop2014 model is scarce, and we rely on information contained in an online two-page abstract (Office of the Actuary, 2014) and discussions with the VetPop2014 team at OACT. As a result, we do not assess the quality of the VetPop2014 model here.

Broadly speaking, VetPop2014 shares a similar projection approach to our model: mortality rates are applied to a baseline population, new Veterans are added to the baseline population over time, and Veterans migrate throughout the projection period. The original baseline population for the VetPop model was Census 2000, as with our projections. (Recall that Census 2010 did not include Veteran status.) Key differences between the models are in data inputs and in migration modeling.

VetPop2014 applies age- and sex-specific mortality rates derived from mortality data that include: (a) Veteran specific information from VA administrative data and (b) U.S. population data from the Social Security Administration and the IRS. VetPop2014 assumes a slight mortality improvement for older Veterans due to longevity improvement, although by 2024 this is negligible. The VetPop2014 model does not incorporate race/ethnic-specific mortality rates. Our model differs here in that we apply race/ethnic-specific (in addition to age- and sex-

---

[59] Based on the 2013 ACS.

specific) rates. As described in A.1.3.3, the mortality rates we use are a modification of the VetPop2014 rates we originally obtained from OACT that also incorporates the national race/ethnic differences in mortality reported by the Centers for Disease Control (CDC). We do not assume any improvement in mortality through the projection period.

VetPop2014 projects annual separations (new Veterans) by age and sex, and by active and reserve component, using Department of Defense data. The abstract states that "[b]ased on DoD's annual military separation data from FY1980 to FY2013 . . . VetPop2014 . . . developed a set of Time Series Models to project annual separations for various age and gender groups. . . . VetPop2014 Model then used historical county separation data based on VA administrative records along with migration information from the IRS to project the county level separation from FY2014 to FY2044 using predictive modeling techniques." VetPop2014 assumes that conflicts in the Gulf end by 2018, and that there are no other major conflicts in the next 30 years. Our model uses individual-level DoD administrative data to derive separation rates by age, sex, race/ethnicity, branch of service, and active and reserve status. Our projected separations reflect branch-specific trends in sex composition and separation rates, which is not reflected in VetPop2014 to our knowledge.[60] Our projected separations also assume no future major conflicts, but we also assume downsizing of the various branches by 2018 following announcements by the Army and our internal estimates for the other branches. It is not clear whether VetPop2014 similarly assumes downsizing. Our model also excludes separations from Reserves and National Guard if they have not served any active duty time (either in the other branches, or while in the Reserves/National Guard). This exclusion is based on the need for consistency with the way ACS measures Veterans as well as the requirement for active duty in order to qualify for VA access. We do not know whether VetPop2014 similarly excludes unactivated Reserves and National Guard. Unlike the VetPop2014 model, the RAND model does not derive geography-based separation rates, but rather geographically distributes new Veterans according to the Veteran age, sex, race/ethnicity, and service era distribution observed in the country at the time.

Finally, VetPop2014 models migration at the county level using historical data from VA, IRS, and the ACS. Predictive migration models are developed for various age (five groups) and sex cohorts. While we do not know more about the VetPop2014 migration models, this is where our models likely differ most. Our migration models are based only on data from the ACS, but the gravity models we use to predict migration from 2014–2024 reflect a wider range of Veteran characteristics: sex, service era, age (15 groups), and race/ethnicity—as well as distance and origin/destination population sizes. All of these characteristics were significant predictors of migration in our models. However, as we noted previously, migration plays a relatively minor role in overall population distribution in our models. We do not know how significant the role of migration is in the VetPop2014 model.

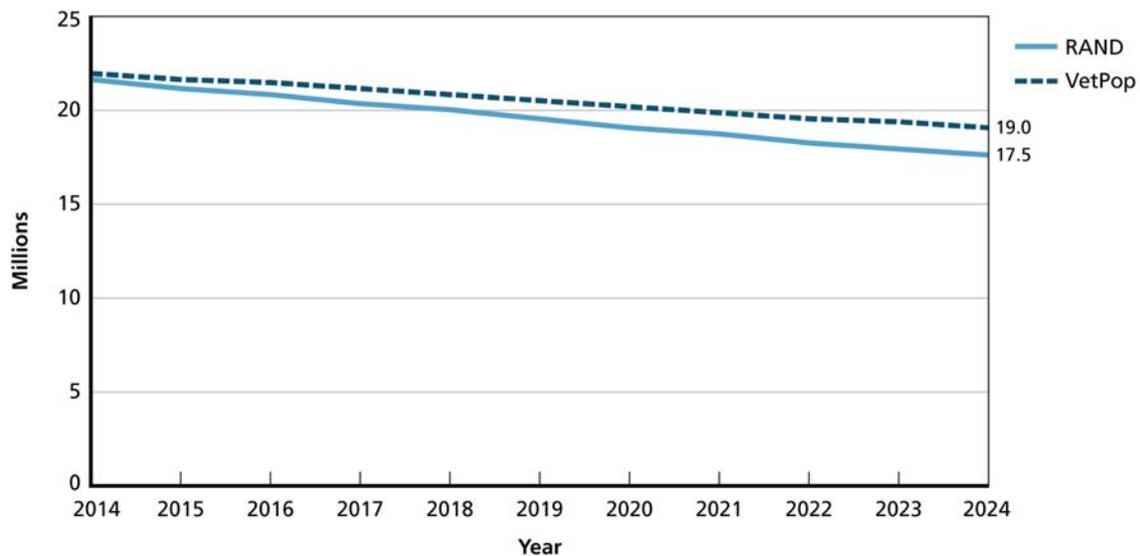
---

[60] The sex composition of the various branches varied in 2014: Women comprised 12 percent of the Army, 19 percent of the Air Force, 16 percent of the Navy, and 7 percent of the Marines according to our data. Similarly, separation rates varied in 2014: 14 percent for the Army, 13 percent for the Navy, 11 percent for the Air Force, and 16 percent for the Marines.

Figure A-3 compares RAND's projections of the number of Veterans with those from VetPop2014. Despite the differences between VetPop2014 and our model, the projected 2024 Veteran populations are relatively similar in size (19 and 17.5 million, respectively) and sex composition (11 percent female in both models). However, there are differences in terms of race/ethnic composition of the Veteran population, as shown in Table 3-2. VetPop2014 predicts slightly higher percentages of black and Hispanic Veterans, while we predict higher percentages of white and Asian Veterans. This is most likely a result of our differing mortality rates (white and Asian Veterans have lower mortality rates than black and Hispanic Veterans in our model, consistent with national mortality rates).

Table A-5. Projected Race/Ethnicity of Veteran Population in 2024, RAND and VetPop2014

	RAND	VetPop2014
Race/Ethnicity		
White	75.8	73.4
Black	12.7	13.9
Hispanic	7.3	8.6
Asian	2.3	1.8
Other	1.9	2.3

Figure A-3. Comparison of RAND and VetPop2014 Projections


SOURCE: RAND analysis of VA, DoD, and Census data, and VetPop2014

As the Veteran population is projected to grow more diverse over time, we suggest that the VetPop2014 model consider race/ethnicity differences in mortality rates. We also encourage detailed methodological documentation of the VetPop2014 model to provide transparency regarding the assumptions and methodology used for VA's projections.

A.2 Detailed Results

To ease tabular presentation of data, we refer to Census Divisions. There are nine Census divisions:

1. Pacific: Alaska, Washington, Oregon, California, and Hawaii

2. Mountain: Montana, Idaho, Wyoming, Nevada, Utah, Colorado, Arizona, and New Mexico

3. West North Central: North Dakota, South Dakota, Nebraska, Kansas, Minnesota, Iowa, and Missouri

4. West South Central: Oklahoma, Texas, Arkansas, and Louisiana

5. East North Central: Wisconsin, Illinois, Indiana, Ohio and Michigan

6. East South Central: Kentucky, Tennessee, Mississippi, and Alabama

7. Middle Atlantic: New York, Pennsylvania, and New Jersey

8. South Atlantic: Maryland, Delaware, West Virginia, Virginia, Washington DC, North Carolina, South Carolina, Georgia, and Florida

9. New England: Vermont, New Hampshire, Maine, Massachusetts, Connecticut and Rhode Island.

Over time, the East North Central and Middle Atlantic areas lose proportionately greater population (from 25 percent to 19 percent), while the South Atlantic area grows from 23 percent to 28 percent of all Veterans. There is slight movement of Asians from the Pacific to South Atlantic region (10 percent reduction/increase).

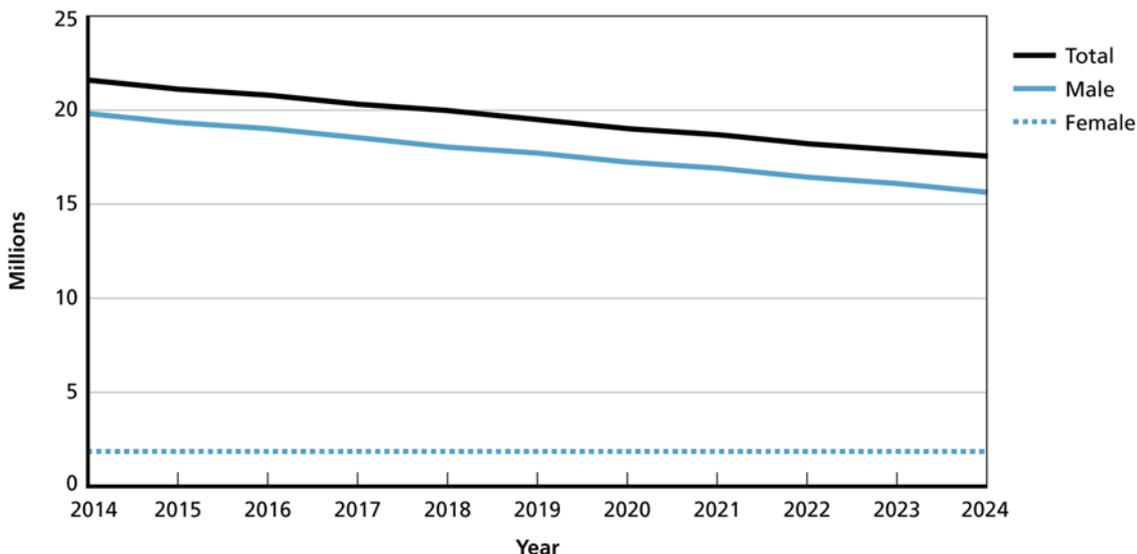
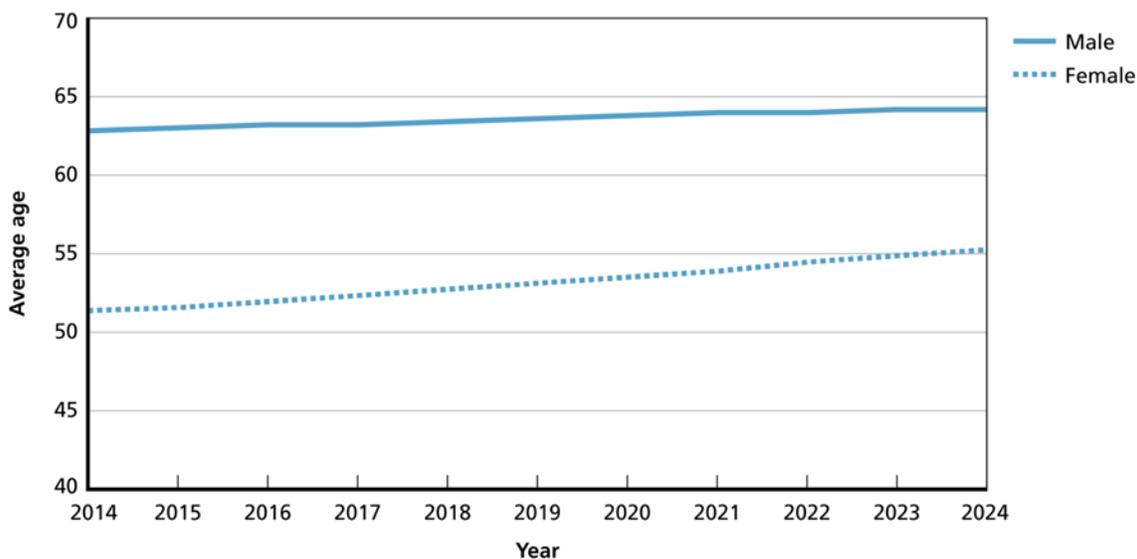
Gulf War and later eras increase from 27 percent to 42 percent of the Veteran population by 2024. There is no substantial geographic redistribution of cohorts.

Figure A-4. Total Population by Sex, 2014–2024


SOURCE: RAND analysis of VA, DoD, and Census data.

While the number of male Veterans is projected to decline steadily, the number of female Veterans is projected to increase very slightly at the same time (Figure A-4). The relative share of female Veterans will increase by 25 percent, from 8 percent to 10 percent of the Veteran population by 2024.

Figure A-5. Average Age by Sex, 2014–2024


SOURCE: RAND analysis of VA, DoD, and Census data.

Veterans' mean age will increase slowly throughout the period (Figure A-5). Male Veterans' mean age will rise much more slowly than female Veterans' mean age, although female Veterans are substantially younger overall.

A.3   Population Projection Sensitivity Analysis

A.3.1   Alternative Models

In this section we examine how the population projections vary when using different mortality rates. Recall that the rates used in the RAND Veteran projection are based on a combination of the VetPop2014 mortality rates and national-level race/ethnic-specific mortality rates from the CDC.

Here we apply mortality rates from (1) the VetPop2014 model (no race/ethnic differences in rates), (2) the observed national-level mortality rates from the CDC, and (3) a significantly elevated risk of mortality linked to poverty-area residence identified in other literature.

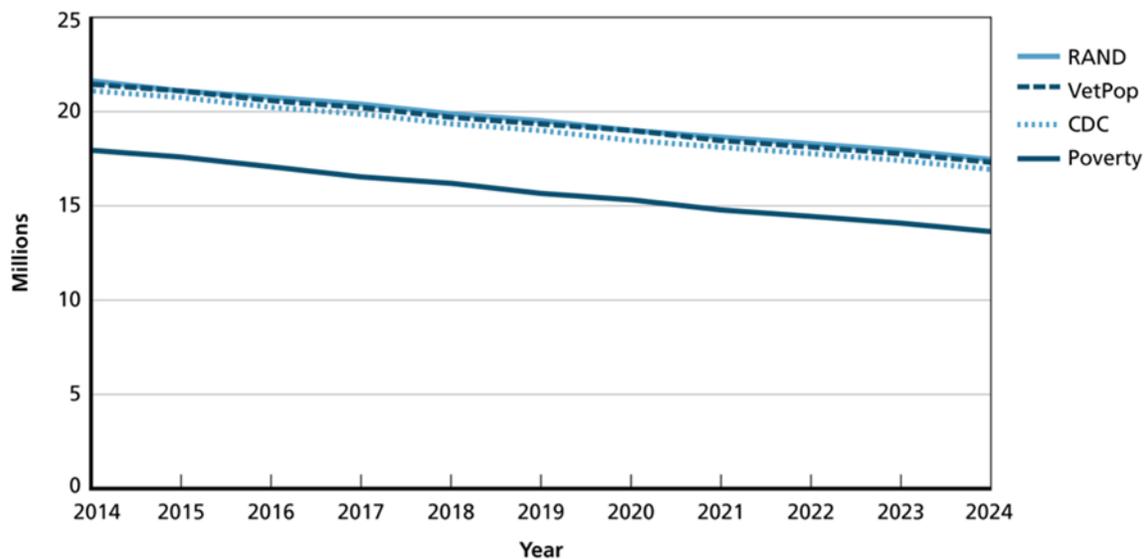
Also recall that our population projections begin from 2000 and continue through 2024. Figure A-17 presents the 2014–2024 period under the four mortality schedules. The RAND projection and VetPop2014 model are virtually equivalent, which is to be expected given that the overall mortality rate was simply distributed across race/ethnic groups. As discussed in A.1.7, although

total Veteran population estimates across the RAND and VetPop2014 projections are similar, there are differences in the race/ethnic composition of the two populations: white and Asian Veterans are slightly more prominent in the RAND projection due to their slightly lower mortality rates than other groups.

Contrasting the RAND projection with the national mortality rates obtained from the CDC indicates that the mortality rates for Veterans are slightly lower than for the nation as a whole. By 2024 the RAND estimate projects 17.5 million Veterans, while using CDC mortality rates on the same population leads to a 2024 population of 17.0 million Veterans. While Veterans may have more health care needs than other civilians (see Section 4), they may also have access to VA care; whereas many civilians may lack health care. Further, Veterans have higher median incomes and are less likely to live below the poverty line than other civilians (National Center for Veterans Analysis and Statistics, 2014b).

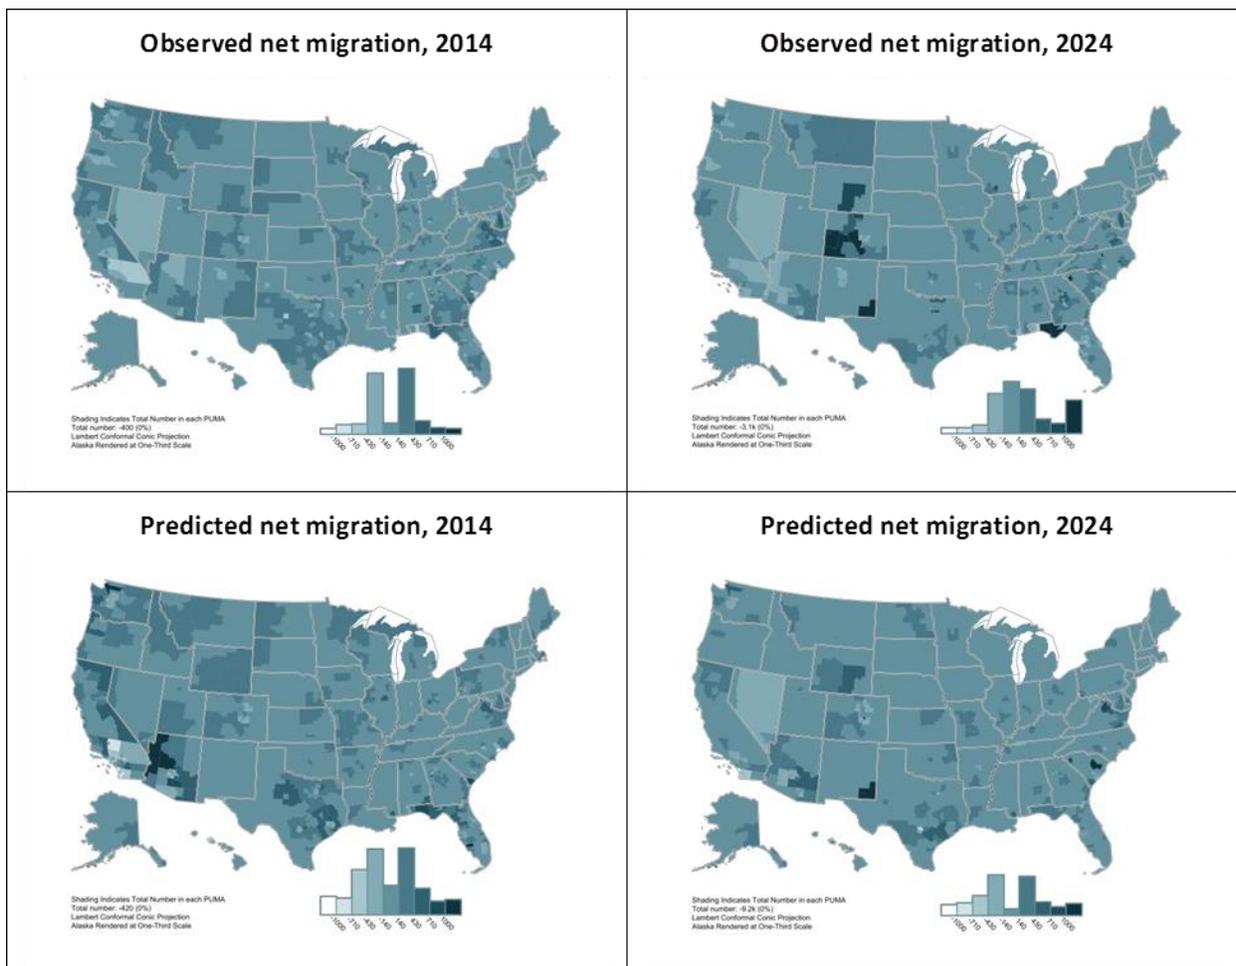
Finally, to examine how highly elevated mortality risk impacts our population projections, we apply the same elevated risk of all-cause mortality associated with poverty-area residence (rate ratio 1.78) that was identified in a longitudinal study of over 10,000 individuals ages 25-74, from 1971 to 1987 (Waitzman & Smith, 1998). There are many studies linking poverty to mortality; this specific one was chosen based on the large sample size and long follow-up period. As it is for illustrative purposes only, it is sufficient for the present needs. Applying nearly doubled mortality rates to the population projection does have a substantial impact, as anticipated: by 2024 the projection estimates a Veteran population of 13.7 million (22 percent lower than the RAND estimate). Again, this estimate assumes all Veterans live in federally designated poverty areas, and is for illustrative purpose only.

Overall, the comparison suggests that the projection is relatively robust to different mortality schedules, assuming the mortality schedules are not extreme.

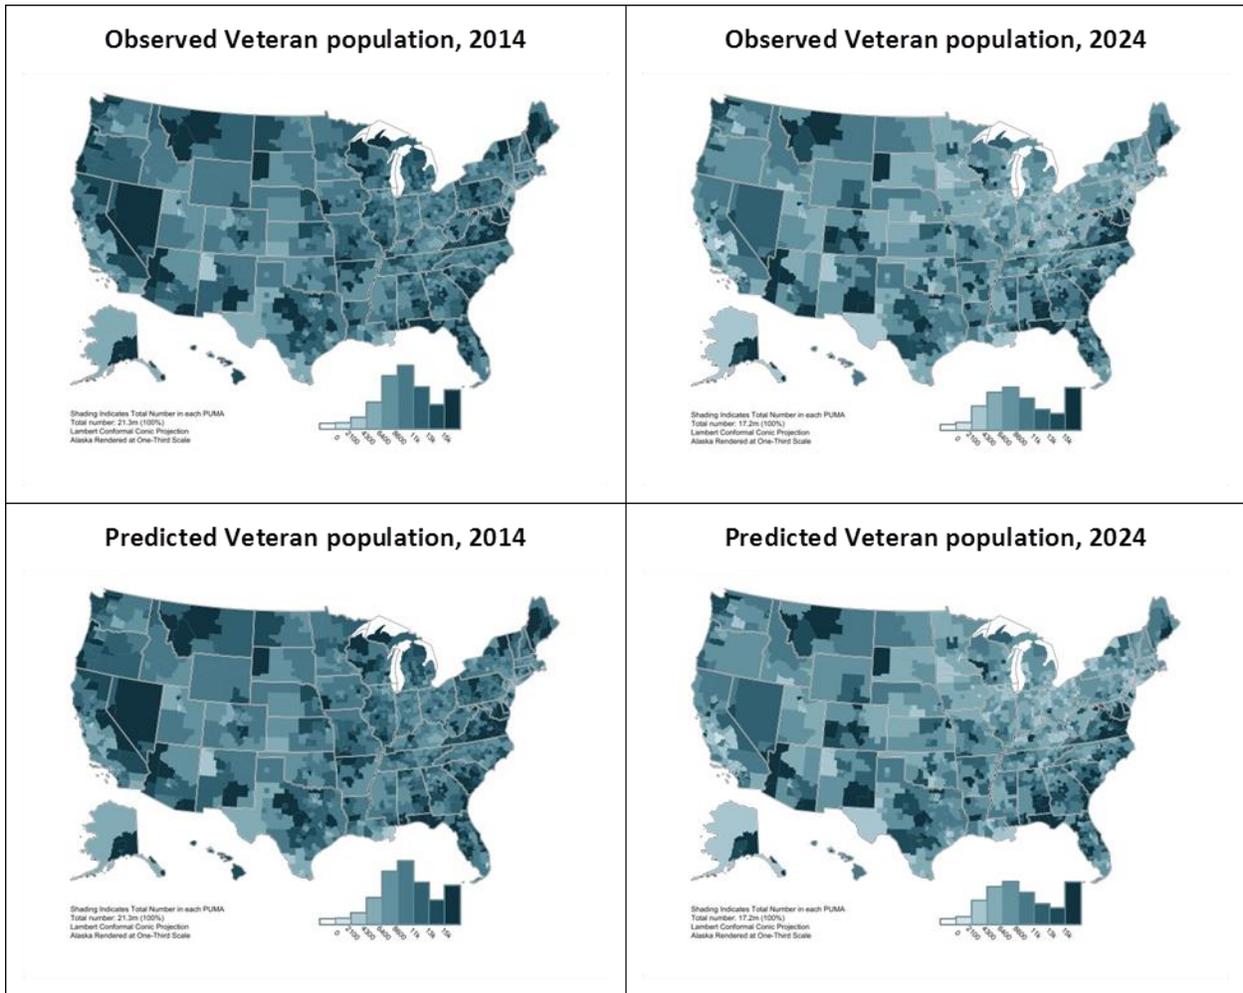
Figure A-17. Model Comparison


A.3.1.1 Comparison of Observed Versus Gravity Model Net Migration in 2014–2024

Net migration estimated with observed in-migration and out-migration rates from 2009–2013 ACS is compared to net migration estimated with predicted in-migration and out-migration rates from gravity models using the same survey. In 2014, there are less PUMAs with stronger negative or positive observed net migration, compared to predicted net migration. In other words, predicted net migration is more evenly distributed across the different categories of migration level than observed net migration. This result might be an indication that gravity models estimate rates that smooth the rates across the country, even though these rates did generate some areas with highly positive net migration in northwest Arizona. By 2024, net migration estimated with predicted rates from gravity models are even more equally distributed across the categories of migration level, compared to observed net migration. As a result, there are fewer areas with strong positive net migration originated with predicted rates than observed rates. Besides these differences, the same general patterns are observed across the country: (1) positive net migration to southeastern New Mexico, northwestern Florida, Colorado, southern Wyoming, western South Carolina, and northern Virginia; and (2) negative net migration from Nevada, Los Angeles, Phoenix, and San Antonio.

Figure A-18. Observed and Predicted Net Migration, 2014 and 2024


Even with some differences between net migration estimated with observed and predicted rates, the overall distribution of Veterans by PUMAs is similar throughout these two approaches. This similarity is probably due to the fact the overall in-migration and out-migration rates are small among the Veteran population. Observed rates varied from 3.03 percent in 2014 to 1.71 percent in 2024, while predicted rates varied from 2.97 percent in 2014 to 1.61 percent in 2024. The team utilizes predicted results originated from gravity models to both net migration and population of Veterans, because they smooth the trends across the small geographical areas of PUMAs and the final results are consistent with observed trends.

Figure A-19. Observed and Predicted Veteran Population, 2014 and 2024


Appendix B   Enrollment in and Reliance on the VA Health Care System

B.1   Statistical model for the number of new enrollees

We used VA administrative data, the Veteran population projections from Section 3, and DoD data to estimate the probability that a yet-to-enroll Veteran enrolls in the VA health care system. Estimates are based on a generalized linear model indexed by age (a), sex (g), CTS deployment status (d), and includes a linear effect of time to capture secular trends in enrollment by year (t):

(1) $NE_{agdt} \sim Binomial(U_{agdt}, p_{agdt})$, with $p_{agdt} = expit(\delta_{a,g} + \theta_d + \eta C_{a,g} + \beta t)$

where NE_{agdt} is the number of new enrollees, U_{agdt} is the number of yet-to-enroll Veterans, p_{agdt} is the probability that a yet-to-enroll Veteran enrolls, $\delta_{a,g}$ is an age-and-sex specific effect, θ_d is the effect of Iraq-Afghanistan deployment on the probability of enrollment, and $C_{a,g}$ is the percentage of Veterans in age group a and sex g who served in Vietnam. The percent of Vietnam Veterans, $C_{a,g}$, is included in the model to disentangle the effect of age and the Vietnam service era on enrollment. This is important because, for example, a 2001 change in VA policy related to presumptive conditions associated with Agent Orange exposure led to an increase in the enrollment rates for Vietnam Veterans when they were in their 50s. Explicitly modeling this effect ensures that we do not predict a sharp increase in enrollment for all service era cohorts as they enter their 50s. We will explore including similar terms for other service cohorts.

Due to data limitations, this model does not distinguish between enrollment rates for Veterans deployed in Iraq and Afghanistan who are within the five-year window of enhanced eligibility and those who are outside of this window. The VA administrative data that we received do not contain information on separation date; therefore, we were unable to distinguish new enrollees who had deployed as part of the conflicts in Iraq and Afghanistan and separated within the past five years from those who had separated more than five years ago. With proper approvals, DoD data on separations and deployment could be merged with VA enrollment data. However, we did not have such approvals.

B.2   Algorithm for projecting VA enrollment

The following algorithm was used to project VA enrollment:

1. Start with the current number of enrollees in an age group a, sex g, and Iraq-Afghanistan deployment status d in year t, E_a^t, suppressing the notation indicating sex and Iraq-Afghanistan deployment status for ease of notation. We observe E_a^{2014}, but this number is projected in all subsequent years.

2. Estimate the number of currently enrolled Veterans who are alive and enrolled in the next year by applying age-specific mortality rates to the current enrollees and increasing their age by one year: $\tilde{E}_{a+1}^{t+1}$

3. Obtain Vet_{a+1}^{t+1} as described in Section 3.

4. Estimate the number of yet-to-enroll Veterans by subtracting the projected number of enrolled Veterans from the total number of Veterans in that year[61]:

$$U_{a+1}^{t+1} = Vet_{a+1}^{t+1} - \tilde{E}_{a+1}^{t+1}$$

5. Estimate the number of new enrollees by applying estimated enrollment rates for year *t+1*, based on equation(1), to the number of yet-to-enroll Veterans:

$$NE_{a+1}^{t+1} = U_{a+1}^{t+1}\widehat{Pr}(Enrollment)$$

(Recall that the probability of enrollment depends on Iraq-Afghanistan Global War on Terror deployment status.)

6. Add the number of new enrollees to the existing population of enrollees:

$$E_{a+1}^{t+1} = \tilde{E}_{a+1}^{t+1} + NE_{a+1}^{t+1}$$

7. Repeat to predict through 2024.

Our algorithm assumes that enrollment rates for Iraq or Afghanistan-deployed Veterans, based on equation (1), differ systematically from other Veterans, but otherwise depends only on age, sex and a linear time-trend. The effect of Iraq-Afghanistan deployment on enrollment (θ_d) is constant over time, so therefore this model does not capture expected decreases in enrollment rates among Veterans who were deployed (see Section 4 for discussion).

We projected the number of enrollees based on three different sets of assumptions on the future probability of new enrollment. First, we assumed that the probability of enrollment will continue to follow the recent pattern of enrollment by directly using equation (1). Second, we assumed that the probability of enrollment among Veterans who were deployed will follow the recent pattern of enrollment among Veterans who never deployed by dropping the θ_d term in equation (1). Third, we assumed that the probability of enrollment among Veterans who deployed will decrease over time by allowing the effect of deployment on future enrollment, θ_d, to decrease by 5 percent each year.

B.3   Projecting the number of VA patients

We projected the number of VA patients from 2014–2024 by multiplying the number of enrollees by the probability of use among enrollees. We estimated the probability that, in a given year *(t)*, a VA enrollee is a VA patient using a generalized linear model applied to individual-level data from the Survey of Enrollees:

(2) $logit(Pr[VA_i = 1]) = \alpha + \gamma_1 age_i + \gamma_2 gender_i + \gamma_3 cohort_i + \gamma_5 GWOT_i + \beta t$

in equation (2) VA_i is equal to 1 if *i*th enrollee is a VA patient, age_i is a vector of five-year age categories, $gender_i$ is indicator for male, $cohort_i$ is a vector of indicators for seven service

---

[61] Note that mortality rates were used in Section 3 to estimate Vet_{a+1}^{t+1}. The number of yet-to-enroll Veterans U_{a+1}^{t+1} incorporates mortality rates indirectly because it is a function of Vet_{a+1}^{t+1} and $\tilde{E}_{a+1}^{t+1}$, both of which incorporate mortality rates.

eras, and $GWOT_i$ is an indicator that the enrollee was deployed as part of Iraq and Afghanistan, and t is a linear effect of calendar year.

B.4 Probability of VA Use by VA Enrollee Characteristics

Table B-1. The Probability That a VA Enrollee Uses VA Health Care: Baseline Model

SOURCE: SoE (2010–2014).
NOTES: Sample size = 209,979. The adjusted probabilities of using VA health care services conditional on enrollment are shown in the first column. The standard errors are in column (2). These estimates show the differences in the probability of VA health service use within each demographic dimension (e.g., age), while controlling for other demographic differences. For example, any differences in the adjusted probabilities of use by age are devoid of the impact of Afghanistan and Iraq deployment on the probability that younger Veterans use VA health services.

Appendix C   Health Care Needs of the Veteran Population

C.1   Data and Analytic Approach

C.1.1   Definitions

C.1.1.1   Veterans

The two main populations of interest are (1) Veterans meeting Department of Veterans Affairs (VA) eligibility requirements (**Veterans**) and (2) Veterans using VA services (**VA patients**). There is also an intermediate population of Veterans enrolled in VA, of which VA patients are a subset, but we did not consider this group in our analyses. The criteria used to identify these two subgroups varied according to the information available in each data source.

Veterans: When using nationally representative surveys, we defined Veterans based on self-reported Veteran status. We used honorable discharge as a proxy of VA eligibility and limited the sample to this population when possible. We also considered separated military personnel in Defense administrative records Veterans.

VA patients: When using nationally representative surveys, we classified Veterans as VA patients if they met any of the following criteria: They reported using VA services, they reported using non-VA services that were paid for by VA, or if there was some indication that VA paid for at least some of the health care services received by the respondent when possible. If the survey did not identify source of payment, we defined VA patients based on self-reported health insurance coverage. In this case, the respondent would likely be misclassified if he or she was enrolled in VA but did not use services. VA patients were identified in VA administrative data as those Veterans who were enrolled in VA and received some health service from VA in the previous year.

C.1.1.2   Definition of Demographic and Geographic Characteristics

Demographic and geographic groups were used throughout the analyses in this section and will be referred to simply as demographics. Standardizing the definition of these groups was imperative for many reasons; most importantly, the population projections of Section 3 were combined with the analyses of this section to produce projections of the health care needs of Veterans and VA patients. By using a standardized definition of demographic characteristics, we ensured seamless integration of the results.

Our analyses attempt to generate results for demographic groups defined by age, sex, race, ethnicity, and geographic area. Where appropriate, additional demographic groups included service cohort (e.g., Vietnam, Afghanistan, Iraq), Veteran versus non-Veteran, and VA patient versus non-VA patient. Table C-1 summarizes the main demographic and geographic characteristics used throughout this section.

	Post 9/11
Geography	
	Public Use Microdata Area (PUMA)

Demographic characteristics were not available in all data sources and in some cases were not available at the same resolution. For example, geographic location was not always available at

the PUMA level, and when this occurred we used available geographic information, such as state or Census region (Northeast, Midwest, South, and West).

C.1.1.3   Health Conditions and Health Behaviors

We considered a common set of key conditions when carrying out analysis of patient-level data (derived from survey, claims, or encounter data) to inform this subtask. We used several sources to identify important conditions. We began with 39 diagnostic groups identified by the VA Healthcare Analysis and Information Group (HAIG); these were chosen on the basis of prevalence, cost, and morbidity. To avoid missing conditions useful for this analysis but of less relevance to the HAIG, we added several conditions based on four different sources. First, we used the Centers for Disease Control and Prevention (CDC) Morbidity and Mortality Weekly Report (MMWR), including indicators of chronic disease (Holt et al., 2015), leading causes of morbidity and mortality (Johnson et al., 2014), 10 conditions associated with the greatest total expenditures (Soni, 2011), common causes of disability among adults (Centers for Disease Control and Prevention, 2009), and from the National Vital Statistics Report "Deaths: Final Data for 2011" (Hoyert & Xu, 2012). Second, we used the Healthcare Cost and Utilization Project's HCUPnet (Agency for Healthcare Research and Quality, undated) and the National Ambulatory Medical Care Survey/National Hospital Ambulatory Medical Care Survey (Centers for Disease Control and Prevention, undated) to identify additional conditions associated with large numbers of discharges in U.S. community hospitals or large numbers of outpatient visits. Third, we used conditions identified in Assessment B as critical for understanding the workforce and infrastructure needs of VA. Fourth, we identified conditions that disproportionately affect Veterans relative to non-Veterans using a review of research studies identified in Task A.1 (Research Question 3) and used the analysis of national survey data described in the Analytic Approach (under Research Question 1). After combining and de-duplicating these lists, we identified codes to be used with administrative data (including ICD-9 or ICD-9 code groupings produced by AHRQ's Clinical Classifications Software [CCS]). (See Appendix C.1.2 below.)

For the final report, we selected health conditions that were either associated with high prevalence rates among Veterans or those that disproportionately affected Veterans in comparison to non-Veterans. Analyses of individual-level survey data used additional self-reported health conditions when available, as well as self-reported difficulty with ADLs and health behaviors, including alcohol use, tobacco use, and exercise.

C.1.2   Identification of Clinical Conditions in Survey and Encounter Data

As discussed below in greater detail, the primary data sources for identifying health conditions among Veterans and non-Veterans were MEPS and encounter data from VA and MHS (the military insurance system for active military service members and dependents). All three data sources included person-level information on conditions based on ICD-9 codes. In the public use files of MEPS, the ICD-9 codes were truncated at the three-digit level or were converted into corresponding CCS codes, which are published by AHRQ (see Healthcare Cost and Utilization Project, 2015). VA and MHS encounter data included full five-digit ICD-9 codes. We used 29 coding algorithms (i.e., combinations of ICD-9 and/or CCS codes) to identify relevant clinical populations within these data sources (see Table C-2).

We identified the algorithms themselves by first searching in PubMed for studies that validated the use of particular ICD-9 codes for specified conditions with good sensitivity and positive predictive value (PPV). We searched PubMed using the following terms: (ICD-9[TIAB] OR international classification of diseases[TIAB] OR international classification of diseases[MH]) AND (validation OR sensitivity OR positive predictive value OR specificity OR accuracy OR ((claims OR administrative) AND data)). If no studies for particular conditions could be identified, we instead used relevant AHRQ CCS categories, which were designed to group conditions into categories suitable for use by health service researchers. If we were unable to identify a relevant CCS category, we identified ICD-9 codes whose descriptions were relevant for that condition.

We used these coding algorithms to directly identify conditions in VA and MHS encounter data. We attempted to identify conditions with greater accuracy by requiring that one inpatient encounter be labeled with the associated ICD-9 codes or that two outpatient encounters are labeled with the associated ICD-9 codes; this is a common approach for identifying conditions within VA encounter data (Bedimo et al., 2009; Justice et al., 2006; Park et al., 2014). We make exceptions for TBI, acute coronary syndrome, and AMI. We identify TBI cases even if there is only a single outpatient or inpatient diagnosis flagged because acute causes of TBI (concussion, skull fracture, etc.) may only be described at the initial visit, per guidance from the Department of Defense (U.S. Department of Defense, 2010). In contrast, we identify acute coronary syndrome and AMI if one or more inpatient stays had a principal diagnosis code associated with those conditions (Petersen et al., 1999). In MEPS data (which lack five-digit ICD-9 codes), we used three-digit ICD-9 codes, CCS codes, or combinations of the two to identify conditions. For example, PTSD has a single ICD-9 code (309.81); this code cannot be uniquely identified using three-digit ICD-9 codes or CCS codes alone, but the combination of the ICD-9 code 309 and the CCS code 651 uniquely identifies PTSD.

Table C-2. Identification of Health Conditions

Condition	ICD-9	Comment
Acute coronary syndrome	410.00; 410.01; 410.10; 410.11; 410.20; 410.21; 410.30; 410.31; 410.40; 410.41; 410.50; 410.51; 410.60; 410.61; 410.70; 410.71; 410.80; 410.81; 410.90; 410.91; 411.1	Per Varas-Lorenzo et al. (2008) (Varas-Lorenzo et al., 2008): "PPVs of the codes 410 and 411 for acute coronary syndrome were 0.96 (95%CI: 0. 92-0.98) and 0.86 (95%CI: 0.83-0.88), respectively." We did not estimate the incidence of acute coronary syndrome using MEPS data because it is unlikely that survey respondents distinguished between recent and remote episodes of acute coronary syndrome.
AMI	410.xx	Per Petersen et al. (1999), PPV of principal diagnosis of 410.xx for AMI is 97%. We did not estimate the incidence of AMI using MEPS data because it is unlikely that survey respondents distinguished between recent and remote episodes of AMI.
All cerebrovascular diseases	430.xx; 431.xx; 432.xx; 433.xx; 434.xx; 435.xx; 436.xx; 437.xx; 438.xx	CCS category
All malignant cancer	140.xx - 209.xx	ICD-9 codes selected had 79% sensitivity, 80 % PPV using hospital discharge records (Brackley, Penning, & Lesperance, 2006).
All mental health conditions	290.xx; 291.xx; 292.xx; 293.xx; 294.xx; 295.xx; 296.xx; 297.xx; 298.xx; 299.xx; 300.xx; 301.xx; 302.xx; 303.xx; 304.xx; 305.xx; 306.xx; 307.xx; 308.xx; 309.xx; 311.xx; V11.xx	No validation study was identified, but a similar range of ICD-9 codes has been used to identify mental health conditions in administrative data (Garvey Wilson, Messer, & Hoge, 2009). Of note, this list excludes disorders of development and childhood.

Condition	ICD-9	Comment
Amputation	V49.74; V49.75; V49.76; V49.77; 897.0; 897.1; 897.2; 897.3; 897.4; 897.5; 897.6; 897.7; V49.70; V49.71; V49.72; V49.73; V49.60; V49.61; V49.62; V49.63; 997.60; 997.61; 997.62; 997.69; 885.0; 885.1; 886.0; 886.1; 895.0; 895.1; 896.0; 896.1; 896.2; 896.3; 905.9; 353.6; V49.66; V49.67; V49.64; V49.65; 887.0; 887.1; 887.2; 887.3; 887.4; 887.5; 887.6; 887.7	We were unable to identify a validation study for ICD-9 codes identifying patients with a history of amputation. ICD-9 codes were identified by searching a database of ICD-9 code descriptions for descriptions related to amputations, or history thereof.
Arthritis	274.xx; 712.xx; 713.xx; 715.xx; 716.xx; 717.xx; 718.xx; 719.xx	We aimed to types of arthritis that are more likely to be due to injury (and possibly related to military service). There was no predefined, validated set of diagnoses for doing this, so we chose broad groups of ICD-9 codes related to non-immunologically mediated arthritis; we excluded diagnoses such as rheumatoid arthritis.
Asthma	493.00; 493.01; 493.02; 493.10; 493.11; 493.12; 493.20; 493.21; 493.22; 493.81; 493.82; 493.90; 493.91; 493.92	ICD-9 codes derived from accepted quality measures related to COPD and asthma (Centers for Medicare & Medicaid Services, 2015b)
Burns	906.5; 906.6; 906.7; 906.8; 906.9; 940.xx; 941.xx; 942.xx; 943.xx; 944.xx; 945.xx; 946.xx; 947.xx; 948.xx; 949.xx	CCS category
Chronic renal failure	403.xx; 404.xx; 581.xx; 582.xx; 583.xx; 585.xx; 586.xx; 587.xx; V56.xx	ICD-9 coding algorithms had poor sensitivity for identifying chronic renal failure in Medicare claims (3-26%), but 90% PPV (Winkelmayer et al., 2005). This version was adapted from Winkelmayer et al. (2005) for use with MEPS.
Colon cancer	153.0; 153.1; 153.2; 153.3; 153.4; 153.5; 153.6; 153.7; 153.8; 153.9; 154.0; 154.1; 154.8; 230.3; V10.05; V10.06	With exception of carcinoid tumors (209.xx), colon cancer otherwise defined as in CCS category (Setoguchi et al., 2007). Use of two ICD-9 codes was 80.4% sensitive, 99.5% specific for colorectal

Condition	ICD-9	Comment
		cancer, and codes had a 69.4% PPV.
COPD	491.0; 491.1; 491.20; 491.21; 491.8; 491.9; 492.0; 492.8; 494.xx; 494.0; 494.1; 496.xx	ICD-9 codes derived from accepted quality measures related to COPD and asthma (Centers for Medicare & Medicaid Services, undated).
Diabetes	250.00; 250.01; 250.02; 250.10; 250.12; 250.20; 250.22; 250.30; 250.32; 250.40; 250.42; 250.50; 250.52; 250.60; 250.62; 250.70; 250.72; 250.80; 250.82; 250.90; 250.92; 250.93; 271.4; 357.2; 648.00; 648.01; 648.02; 648.03; 648.04; 962.3	ICD-9 codes derived from accepted quality measures related to diabetes Types I and II, and are similar to those of CCS category (Centers for Medicare & Medicaid Services, 2015b; Chao et al., 2013; Hirsch & Scheck McAlearney, 2013). Most studies incorporated prescription medication fills, so ICD-9 alone may overstate prevalence; however requiring medication fills would exclude diet-treated diabetes.
GERD	530.11; 530.81	We were unable to identify a validation study for ICD-9 codes identifying patients with a history of GERD. ICD-9 codes were identified by searching a database of ICD-9 code descriptions for descriptions related to reflux, or history thereof.
Hearing loss	389.xx	No validation study identified, but 389.xx encompasses hearing loss ICD-9 codes
Heart failure	398.91; 428.0; 428.1; 428.20; 428.21; 428.22; 428.23; 428.30; 428.31; 428.32; 428.33; 428.40; 428.41; 428.42; 428.43; 428.9; 425.0; 425.1; 425.11; 425.18; 425.2; 425.3; 425.4; 425.7; 425.8; 425.9	ICD-9 codes derived from accepted quality measures related to heart failure (Centers for Medicare & Medicaid Services, 2015b)
Hypertension	401.xx; 402.xx; 403.xx; 404.xx; 405.xx	Per Quan et al. (2009): "The administrative data hypertension definition of '2 claims within 2 years or 1 hospitalization' had the highest validity relative to the other definitions evaluated (sensitivity 75%, specificity 94%, PPV 81%, negative predictive value 92%, and κ 0.71)." Study used ICD-9 401.xx, 402.xx,

Condition	ICD-9	Comment
		403.xx, 404.xx, 405.xx.
IHD	410.xx; 411.0; 411.1; 411.8; 411.81; 411.89; 412.xx; 413.0; 413.1; 413.9; 414.0; 414.00; 414.01; 414.06; 414.2; 414.3; 414.4; 414.8; 414.9; V45.81; V458.2	CCS category
Lipid disorders	272.0; 272.1; 272.2; 272.3; 272.4	CCS category
Major depression	296.2x; 296.3x	Derived from Fiest et al. (2014) but definition not useful in MEPS public-use data, and Fiest et al. (2014) found that depression coding was not reliable in VA (~30% sensitivity).
Musculoskeletal conditions associated with chronic pain	715.95; 715.96; 717.6; 717.7; 717.9; 718.46; 719.40; 719.45; 719.46; 720.07201; 720.2; 721.3; 721.42; 721.7; 721.90; 721.91; 722.10; 722.52; 722.6; 722.70; 722.73; 722.80; 722.82; 722.83; 724.00; 724.02; 724.2; 724.3; 724.5; 724.6; 724.79; 724.8; 724.9; 726.5; 726.64; 729.1; 729.90; 733.92; 733.98; 736.6; 738.4; 756.11; 756.12; 805.4; 836.0; 836.1; 843.9; 844.; 844.0; 844.1; 844.2; 846.0; 846.1; 846.8; 846.9; 847.2; 847.3; 847.4; 847.9; 905.1; 907.2; 907.3; 953.2; 953.3; 953.4	We did not identify a study that validated an algorithm for case identification of musculoskeletal conditions against a gold standard. Instead, we derived this algorithm from Beehler et al. (2013), which aimed to identify patients with chronic pain due to musculoskeletal conditions within the VA ambulatory population. Of note, the definition from Beehler et al. excludes many acute musculoskeletal conditions, such as fractures, in order to identify musculoskeletal conditions more similar to other categories used in the assessment, which primarily concern chronic conditions. This definition also excludes non-musculoskeletal conditions associated with chronic pain.
PTSD	309.81	McCarron et al. (2014) noted that ICD-9 code 309.81 has PPV >89% in VA data; Holowka et al. (2014) noted accuracy for one-year prevalence of PTSD is about 70% (sensitivity 91.4%, specificity 80.9) with ICD-9 code 309.81.

Condition	ICD-9	Comment
Prostate cancer	185.xx; 233.4; V10.46	ICD-9 codes selected had 73% sensitivity, 79% PPV (Brackley et al., 2006).
Schizophrenia	295.xx	Algorithm not validated but used in Hsu et al. (2008) study of VA mental health. We excluded ICD-9 codes for non-specific psychosis to avoid using episodes of psychosis not associated with schizophrenia, such as 289.9 (psychosis not otherwise specified).
Spinal cord injury	344.9; 344.8; 907.5; 907.9; 344.2; 344.3; 344.30; 344.31; 344.32; 344.4; 344.40; 344.41; 344.42; 344.5; 344.60; 344.61; 344.81; 344.89; 907.1; 907.3; 907.4; 952.00; 952.01; 952.02; 952.03; 952.04; 952.05; 952.06; 952.07; 952.08; 952.09; 952.10; 952.11; 952.12; 952.13; 952.14; 952.15; 952.16; 952.17; 952.18; 952.19; 952.2; 952.3; 952.4; 952.8; 952.9; 806.38; 806.39; 806.4; 806.5; 806.60; 806.61; 806.62; 806.69; 806.70; 806.71; 806.72; 806.79; 806.8; 806.9; 907.2; 806.00; 806.01; 806.02; 806.03; 806.04; 806.05; 806.06; 806.07; 806.08; 806.09; 806.10; 806.11; 806.12; 806.13; 806.14; 806.15; 806.16; 806.17; 806.18; 806.19; 806.20; 806.21; 806.22; 806.23; 806.24; 806.25; 806.26; 806.27; 806.28; 806.29; 806.30; 806.31; 806.32; 806.33; 806.34; 806.35; 806.36; 806.37; 344.0; 344.00; 344.01; 344.02; 344.03; 344.04; 344.09; 344.1	CCS category combined with non-validated ICD-9 algorithm used in Netherlands study (Hagen et al., 2009; van Asbeck, Post, & Pangalila, 2000); Hagen et al. (2009) used combinations of 344.x, 907.2, 806.x, 952.x; study showed the codes had good specificity (>90%) but poor sensitivity, but this combination of all codes was not tested.

Condition	ICD-9	Comment
Substance abuse	303.90; 305.00; 305.90; 303.93; 305.20; 305.03; 304.00; 303.91; 304.20; 304.30; 305.60; 304.80; 304.90; 305.01; 304.23; 291.81; 292.84; 305.02; 304.01; 305.63; 304.31; 305.50; 304.21; 303.00; 305.23; 304.03; 304.40; 304.33; 303.92; 292.0; 305.22; 305.21; 305.70; 291.89; 304.10; 304.83; 303.01; 305.62; 305.93; 304.43; 304.22; 305.40; 305.53; 304.70; 305.61; 291.0; 304.32; 304.60; 292.89; 305.73; 305.51; 304.41; 304.73; 305.91; 304.71; 292.81; 304.11; 304.81; 304.02; 291.9; 303.02; 292.12; 304.93; 304.91; 305.52; 303.03; 305.71; 304.63; 305.72; 304.13; 305.43; 305.92; 304.92; 292.11; 304.42; 291.1; 291.3; 305.41; 305.30; 304.61; 304.82; 305.42; 304.72; 305.33; 292.2; 304.12; 304.50; 304.62; 304.53; 292.82; 291.5; 304.51; 305.31; 305.80; 305.32; 291.4; 304.52; 292.83; 305.81; 305.83; 305.82	Definitions drawn from Watkins et al. (2011) and derived using expert assessment, although it was not validated.
TBI	800.xx; 801.xx; 803.xx; 804.xx; 850.xx; 851.xx; 852.xx; 853.xx; 854.xx; 310.2; 950.1; 950.2; 950.3; V15.52; 959.01; 905.0; 907.0	Used VA list of ICD-9 codes corresponding to TBI (Taylor, 2012). Carlson et al. (2013) found 70% sensitivity, 85% PPV in population that screened positive for potential TBI, but validation study for entire VA population not found.
Viral Hepatitis and Hepatitis C	070.4; 070.5; 070.6; 070.7	CCS category; in MEPS this includes all viral hepatitis because it is not possible to separate hepatitis C and hepatitis at 3 digit level OR via CCS. Kramer et al. (2008) showed 93% PPV, 92% NPV for hepatitis C in VA patients with HIV. Niu, Forde, & Goldberg (2015) showed that 1 inpatient or 2 outpatient ICD-9 codes for Hepatitis C had 88% PPV.

Condition	ICD-9	Comment
Vision loss	367.0; 367.1; 367.20; 367.21; 367.22; 367.31; 367.32; 367.4; 367.51; 367.52; 367.53; 367.81; 367.89; 367.9; 368.00; 368.01; 368.02; 368.03; 368.10; 368.11; 368.12; 368.13; 368.14; 368.15; 368.16; 368.2; 368.30; 368.31; 368.32; 368.33; 368.34; 368.40; 368.41; 368.42; 368.43; 368.44; 368.45; 368.46; 368.47; 368.51; 368.52; 368.53; 368.54; 368.55; 368.59; 368.60; 368.61; 368.62; 368.63; 368.69; 368.8; 368.9; 369.00; 369.01; 369.02; 369.03; 369.04; 369.05; 369.06; 369.07; 369.08; 369.10; 369.11; 369.12; 369.13; 369.14; 369.15; 369.16; 369.17; 369.18; 369.20; 369.21; 369.22; 369.23; 369.24; 369.25; 369.3; 369.4; 369.60; 369.61; 369.62; 369.63; 369.64; 369.65; 369.66; 369.67; 369.68; 369.69; 369.70; 369.71; 369.72; 369.73; 369.74; 369.75; 369.76; 369.8; 369.9; V41.0	CCS category, which includes mild vision loss
Women's health	V10.41; V10.44; V10.40; V10.43; V10.42; 179.xx; 180.xx; 181.xx; 182.xx; 183.xx; 184.xx; 218.xx; 614.1; 614.1; 614.2; 614.6; 616.2; 616.3; 617.0; 617.1; 617.2; 617.3; 617.4; 617.9; 618.0; 618.00; 618.01; 618.02; 618.03; 618.04; 618.05; 618.09; 618.1; 618.2; 618.3; 618.4; 618.5; 618.6; 618.7; 618.8; 618.81; 618.82; 618.83; 618.84; 618.89; 618.9; 619.0; 619.1; 619.2; 619.8; 619.9; 620.0; 620.1; 620.2; 620.4; 620.5; 621.0; 621.1; 621.2; 621.3; 621.30; 621.31; 621.32; 621.33; 621.34; 621.35; 621.4; 621.5;	Represents conditions for which surgery is indicated, and uses ICD-9 codes provided by consultation from subject matter experts at VA.

Condition	ICD-9	Comment
	621.8; 621.9; 622.0; 622.1; 622.10; 622.12; 622.4; 622.5; 622.7; 623.0; 623.7; 623.8; 623.9; 624.02; 624.6; 624.8; 624.9; 625.5; 625.6; 628.0; 628.1; 628.2; 628.3; 628.4; 628.8; 628.9; 629.0; 629.1; 629.3; 629.31; 629.32; 629.8; 629.81; 629.89; 629.9; 633.xx; 634.xx; 752.42	

C.1.3   Data Sources

The analysis relied on several data sources, including Veteran survey data and nationally representative survey data (that include some measure of Veteran status) and administrative data provided by VA. The passages following Table C-3 briefly discuss the main advantages and limitations of each available data source.

Table C-3. Summary of Data Sources

Data File	Population	Health	Geographic Location	Veteran Status	VA Enrolled	VA Patient
Nationally Representative Surveys						
MEPS[a]	Civilians, Veterans, VA patients	Yes	Census region	Yes	Yes	Yes
NHIS[b]	Civilians, Veterans, VA enrollees	Yes	Census region	Yes	Yes	Yes
BRFSS[c]	National Veterans, civilians	Yes	State	Yes	Yes	Yes
U.S. Census	Civilians, Veterans	No	Yes	No	No	No
ACS[d]	Civilians, Veterans, eligible Veterans, enrollees	Limited	Yes	Yes	Yes	No
Veteran/VA Surveys						
NSV	Veterans	Limited	No	Yes	Yes	Yes
SoE	VA enrollees	Limited	Yes	Yes	Yes	Yes
Administrative Data						
VA Encounter	VA patients	Yes	Yes	Yes	Yes	Yes
VA Enrollment	VA patients, VA enrollees	No	Yes	Yes	Yes	Yes
MHS	Active duty military	Yes	Yes	N/A	N/A	N/A
Active Duty Master and Loss	Active duty military	No	No	N/A	N/A	N/A
Work Experience	Service members	No	No	N/A	N/A	N/A
Contingency Tracking System	Service members	No	Yes	N/A	N/A	N/A

Note: For the survey data sources, details vary regarding how Veteran status, enrollee states, and patient status is assessed. Table 2-4, below, reports details on Veteran status is determined. Enrollee status is typically based on a self-report of enrollment or use of VA insurance. Patient status may be inferred in some cases based on utilization of VA services, or payment for services by the VA.

MEPS is a recurring, nationally representative longitudinal survey of the U.S. civilian noninstitutionalized population drawn from the NHIS sampling frame. The individual-level data contain information on Veteran status (but does not include information on service era), age, sex, race/ethnicity, marital status, education, and income. Health information is obtained using

open-ended questions about medical conditions present during the past year. These open-ended responses are then collapsed into ICD-9 codes.

MEPS is the only publicly available data source from which we can estimate diagnosed prevalence rates for all Veterans (who are defined based on self-report of being honorably discharged by the military).[62] We infer whether an individual in the MEPS is a VA patient based on the respondents' source of payment for health care. Specifically, we defined active VA patients as those respondents who had any payment by VA for services used. Unfortunately, the MEPS data do not enable us to identify all Veterans who are eligible for VA services; we can identify only those eligible Veterans who use VA services. There are also some specific conditions for which MEPS is incapable of providing reliable estimates due to sample size limitations; these primarily consist of relatively rare conditions, such as polytrauma, TBI, and medically unexplained illness. The analyses use data from 2006 to 2012.

The **National Health Interview Survey (NHIS)**, sponsored by the CDC, is an individual-level annual survey that includes information on demographics, Census region, general health, cancer screening, and self-reported medical conditions (including asthma, arthritis, cancer, diabetes), health behaviors (including alcohol use, smoking, exercise), physical or functional limitations, and mental health (adult mental health, stress). We defined eligible Veterans to be those who self-reported having served in active military duty. It is not possible to identify VA patients in this data. We analyzed data from 2011 to 2013, which cover the period when military service information is available. We used NHIS to estimate the prevalence of the selected health conditions among Veterans and non-Veterans. Where possible, we compared these estimates from those derived using MEPS which were based on ICD-9-based health conditions.

The **Behavioral Risk Factor Surveillance System (BRFSS)**, sponsored by the CDC, is a nationally representative survey fielded monthly by state health departments that collects individual-level information on health behaviors and risk factors associated with the leading causes of premature mortality and morbidity among adults in the United States. We used data covering 2013. The survey allows for periodic experimental modules and for states to ask additional questions beyond the core instrument. The survey asks whether respondents have ever served in active military duty in the core instruments, and we used this response to identify Veterans. There are also several experimental modules (for certain states) that have asked more detailed questions about deployment, service, and a few specific Veterans' health issues (e.g., PTSD, traumatic brain injury), but we did not use this information because the sample sizes were small and the populations were not nationally representative. We used BRFSS to estimate the prevalence of the self-reported health conditions among Veterans and non-Veterans. BRFSS was also used to examine differences in health behaviors (e.g., smoking) and other health indicators (e.g., obesity) between Veterans and non-Veterans.

---

[62] Prior to 2006, the survey instrument asked whether anyone in the household had *ever served on active duty in the Armed Forces of the United States* [emphasis added].

The **VA Survey of Veteran Enrollees Health and Reliance Upon VA (SoE)** is a recurring nationwide survey of more than 40,000 Veterans enrolled in the VA system. The survey includes each enrollee's demographic and socioeconomic characteristics, general health status, period of military service, and priority group (from administrative record). It also includes information relevant to enrollees' relationships with the VA system, including when and why individuals enrolled in VA, health insurance coverage, long-term care insurance, use of VA and non-VA services, and payer information. We used this survey to determine the characteristics of Veteran VA enrollees predicting use (or non-use) of VA services and, in combination with demographic projections, future rates of VA use.

VA encounter data include individual-level information on diagnoses, demographic characteristics and geographic location (state). VA encounter data was used to estimate current and prior condition prevalence patterns among active VA patients. This data set has larger sample sizes which allow us to estimate the prevalence of service-connected health conditions that exhibit very low prevalence in the national population. A limitation of these data is that it does not capture Veterans not enrolled in VA. Moreover, the database includes only health conditions of VA patients that were treated at VA. This may represent only a subset of total health conditions if VA patients also seek care from non-VA providers. Most Veterans with service-connected disabilities use VA (RAND analysis of FY14 VHA Support Service Center Current Enrollment Cube Data), so the prevalence estimates for these conditions are expected to be more representative of the overall prevalence in the Veteran population.

The **VA Enrollment** are derived from the Health Eligibility Center enrollment files via the ADUSH enrollment file. The data include the counts of VA patients and VA enrollees by state of residence, sex, age group, and Iraq-Afghanistan deployment status. We used data covering the period 2005–2014.

MHS encounter data include information on diagnoses and demographic characteristics of active military personnel. We used MHS encounter data to estimate the prevalence of health conditions among separating personnel, which may be useful in predicting health conditions among future VA service users and in determining variation in demand for VA services by health condition.

The **DMDC Loss Files** are administrative data used to identify recently separated military personnel. The DMDC Loss files were linked to the MHS encounter data using a scrambled identifier.

The **Work Experience (WEX) file** contains a longitudinal record for each individual who has served in the active or reserve forces since September 1990. The file contains information on service/component/reserve category, pay grade, occupation (primary, secondary, or duty), and unit identification code. The WEX is built from information in DMDC's Active Duty Master Personnel Edit file, equivalent reserve files, and the underlying service files.

The **Contingency Tracking System (CTS)** data are administrative data that indicate whether active military personnel were ever deployed. These data were linked to the DMDC Loss Files to track the fraction of separating soldiers that were every deployed over time.

C.1.4　Prevalence Estimated from Surveys Versus Administrative Health Records

Our findings are based on data from both the MEPS survey and VA administrative health records, which can lead to differences in estimated prevalence of disease. We reviewed the literature to assess the sensitivity and robustness of our estimates.

We identified four studies of North American populations that compared self-reported health conditions to findings from administrative health records that in these studies are considered the reference standard or "gold" standard (Martin, Leff, Calonge, Garrett, & Nelson, 2000; Muggah, Graves, Bennett, & Manuel, 2013; Okura, Urban, Mahoney, Jacobsen, & Rodeheffer, 2004; Singh, 2009). Table C-4 below summarizes these four studies, describing the survey or administrative data used as well as the population covered and the reference standard data used.

Table C-4. Summary of Published Studies Comparing Self-Reported versus Administrative Health Data

Description	Muggah et al., 2013	Singh, 2009	Okura et al., 2004	Martin et al., 2000
Survey Instrument	Canadian Community Health Survey	Veteran's Quality of Life Study	"Has a medical provider ever told you that you had any of following conditions?"	Behavioral Risk Factor Survey
Reference Standard	Diagnostic codes in Annual Health Review (AHR)	VA medical records: ICD-9 codes and pharmacy records	Medical Record Review	Diagnostic codes in AHR
Population	Ontario	Veterans who received care at VA Veterans Integrated Service Network-13 facilities	Minnesota	Colorado HMO
N	85,459	40,508	2,037	599

These four studies reported the sensitivity and specificity across conditions (see Table C-5). The high specificity across conditions reflects the low chance that respondents report a condition that is not found in the medical record. Sensitivity varied across conditions and tended to be highest for diabetes and hypertension. Sensitivity may be higher for chronic conditions that

require ongoing care than episodic or acute conditions. Differences in sensitivity and specificity across studies could arise because of differences in populations studied, differences in the reference standard, and differences in how completely administrative health records captured health care.

Table C-5. Summary of Published Comparisons of Health Conditions based on Self-Report versus Administrative Health Data

Health Condition	Sensitivity	Specificity	Sensitivity*	Specificity*	Sensitivity	Specificity	Sensitivity	Specificity
Diabetes	0.73	0.99	0.91	0.95	0.66	0.99	0.73	0.99
Hypertension	0.65	0.96			0.82	0.92	0.83	0.83
CHF	0.26	0.99						
Stroke	0.49	0.99			0.78	0.99		
Asthma	0.55	0.96						
COPD	0.26	0.97						
Depression			0.72	0.82				
AMI					0.89	0.98		
Hypercholesterolemia							0.59	0.94

NOTES: * Singh (2009) treated self-report as the reference standard, implicitly assuming that VA health records do not completely capture medical care received by Veterans. The sensitivity and specificity reported correspond to the positive and negative predictive values reported by Singh (2009) (i.e., sensitivity and specificity using the medical record as the reference standard).

Direction of Bias in Self-report data: A review by Bhandari and Wagner (2006) concluded that respondents tend to under-report health care utilization, especially for recall periods longer than six months (they reported on recall of up to 12 months). This is consistent with findings by Muggah et al. (2013), who found that estimated prevalence of health care conditions based on self-report tended to be lower than estimates based on administrative health records. In contrast, a study by Zuvekas and Olin (2009) found close agreement between survey-reported utilization from MEPS and Medicare claims data among Medicare-enrolled respondents. Inconsistencies between self-report and medical records were more likely for men and patients with less education (Okura et al., 2004; Singh, 2009).

Consistency Across Surveys: Li et al. (2012) estimated prevalence of a range of health conditions using NHIS, BRFSS, and NHANES surveys, and found that these surveys produced similar estimated prevalence of diabetes, hypertension, and stroke. An earlier comparison by Fahimi, Link, Mokdad, Schwartz, and Levy (2008) produced similarly reassuring findings. Many of the issues related to BRFSS are attributable to the use of landline phones; it is not clear whether inclusion of cell phones in the sampling frame (since 2011) has ameliorated bias problems. Earlier studies have found that compared to BRFSS responders, non-responders tend

to be younger, non-White, less educated, non-English speakers, and unmarried (Voigt, Koepsell, & Daling, 2003).

C.1.5   Analytic Approach

All analyses of survey data were weighted using survey sampling weights to ensure the representativeness of the results. Weights were distributed with each survey dataset and typically accounted for the sampling design and nonresponse. We adjusted standard errors for clustering at the person-level in estimations where panel data were treated as repeated cross-sections (e.g., MEPS data, which generally includes two years of data for each survey respondent).

C.1.5.1   Current Differences in the Prevalence of Health Conditions between Veterans and Non-Veterans

Differences in the prevalence of health conditions between Veterans and non-Veterans can be summarized by comparing observed prevalence rates between the two groups. Any observed differences in prevalence provide insight that the two populations are different. However, this approach alone cannot separate prevalence differences due to the varying demographic composition of Veterans and non-Veterans from prevalence differences due to other factors. In order to identify the "unique" health care needs of Veterans, it is important that estimated differences between Veterans and non-Veterans do not capture differences in the demographic characteristics between the two groups. For example, we expect Veterans to have a higher prevalence of hypertension than non-Veterans because Veterans are known to be older when compared with non-Veterans, and the prevalence of hypertension increases with age. For a complete summary of the demographic differences between Veterans and non-Veterans, see Table C-18.

To account for any demographic differences between Veterans and non-Veterans, we calculated adjusted prevalence rates. An adjusted prevalence uses a model to predict the prevalence of a health condition for a reference population. This is achieved by predicting the prevalence of a health condition for a set of observations that has the same demographic composition as the population of interest. In our case, the population of interest is the Veteran population. Thus, the non-Veteran adjusted prevalence estimates the prevalence among non-Veterans if their demographic composition matched the demographic composition of Veterans, and the adjusted Veteran prevalence estimates the prevalence among Veterans using the demographic composition of Veterans.

All comparisons made between Veterans and non-Veterans using adjusted prevalence rates account for the different demographic composition of the two populations. Therefore, any remaining differences after adjustment can be attributed to factors other than demographics (e.g., military service or deployment). This provides insight into health conditions that are unique to Veterans—those that are attributable to factors other than the demographic composition of the Veteran population.

As discussed above, calculating adjusted prevalence rates for Veterans and non-Veterans requires a model that predicts the prevalence of health conditions by Veteran status and other

demographics. Below, we discuss the logistic regression model we used and the associated notation:

1. i represents an individual captured in the survey or administrative data of interest.

2. For each individual, $H_i = 1$ denotes the presence of a health condition or behavior of interest as identified by relevant ICD-9 or by self-reported measures, or $H_i = 0$ if the condition is absent.

3. Vet_i indicates whether the individual is a Veteran ($Vet_i = 1$ for Veterans and $Vet_i = 0$ for non-Veterans).

4. Z_i is a vector of mutually exclusive demographic and geographic indicator variables defined by individual i's geographic location (either Census Region [Northeast, Midwest, South and Midwest] or state), age category (5- or 10-year intervals), sex, and race/ethnicity. Service cohort is not available in MEPS, which is the principal data source for this analysis; the effect of particular service cohorts can only be indirectly approximated by determining how differences between Veterans and non-Veterans vary with age.

5. X_i is a vector of individual characteristics that are associated with a given health condition, and that may be associated with differences in disease prevalence, including whether the individual lives in an urban location, marital status, education, employment/student status, smoking, and health insurance coverage.

We chose to use logistic regression models at the individual level of the form:

$$(1) \ logit(Pr[H_i = 1]) = \alpha + \gamma_1 Vet_i + \gamma_2 Z_i + \gamma_3 Vet_i * Z_i + X_i\beta + f(\tau_i)$$

where τ_i is the calendar year of observation i, and $f(\tau_i)$ is some function of time (e.g., a spline function or a set of year indicators). The function $f(\tau_i)$ accounts for time trends in the prevalence of health conditions. The interaction term ($\gamma_3 Vet_i * Z_i$) allows differences in prevalence between Veterans and non-Veterans to vary by demographic characteristics.

Let $\hat{h}_1(Vet_i, Z_i, X_i, \tau_i) = expit(\hat{\alpha} + \hat{\gamma}_1 Vet_i + \hat{\gamma}_2 Z_i + \hat{\gamma}_3 Vet_i * Z_i + X_i\hat{\beta} + \hat{f}(\tau_i))$ be the estimated prevalence for an observation in year τ_i with demographics Z_i, Veteran status Vet_i, and covariates X_i. The non-Veteran adjusted prevalence for year τ in demographic group Z is given by:

$$(2) \ \hat{p}^{adj}_{non-Vet} = \frac{1}{N_{vet}}\sum_{i: Vet_i=1 \ \& \ Z_i=Z} w_i \ \hat{h}_1(0, Z, X_i, \tau)$$

where w_i is the survey weight and $N_{vet} = \sum_{i: Vet_i=1 \ \& \ Z_i=Z} w_i$. This amounts to a weighted average of estimated prevalences among Veterans with demographics Z, where the estimated prevalence is evaluated for $Vet = 0$ in year τ. In other words, this estimates the prevalence of a health condition among Veterans with specific demographics as if (contrary to fact) they had been non-Veterans. The adjusted prevalence for Veterans in year τ and demographic group Z is given by:

$$(3) \ \hat{p}^{adj}_{Vet} = \frac{1}{N_{vet}}\sum_{i: Vet_i=1 \ \& \ Z_i=Z} w_i \ \hat{h}_1(1, Z, X_i, \tau)$$

where everything is as before. Note that the only difference between the Veteran and non-Veteran adjusted prevalence is that the Veteran adjusted prevalence sets the Veteran status to 1 for all observations, and the non-Veteran adjusted prevalence sets the Veteran status to 0 for all observations.

We considered 14 age groups, four census regions, two sexes, and five races/ethnicities. All of the possible combinations among these characteristics represent 560 different demographic subgroups. If estimates for the prevalence of a health condition in any one subgroup were calculated using only data from that subgroup (a stratified estimation approach), each subgroup would need a sufficient sample size to provide a stable prevalence estimate. However, MEPS has only about 4,000 total VA patients, so many of the 560 possible subgroups do not have a sufficient sample size to obtain precise estimates of prevalence using this stratified approach. For this reason, we instead used a regression approach that uses *all available data* to estimate the prevalence. This is achieved by breaking the prevalence down into five factors: (1) a baseline prevalence, (2) the association with age, (3) the association with Census region, (4) the association with sex, and (5) the association with race. Each of the factors is estimated using data pooled across all other demographic characteristics. For example, the association of being an older patient with disease prevalence is estimated using the *entire population*, and this association is applied to all of the subgroups that include older patients. Put another way, the regression approach implies that the association of age with a heath condition is the same across all other demographic characteristics—that is, the effect of age is similar for males and females, blacks and whites, and so on.

Specifying a model with an extremely rich set of covariates X_i increases the risk of including factors endogenous to the Veteran experience; in other words, experience in the military may lead to differences in education, marital status, and other characteristics. Including these variables in the analyses might minimize differences between Veterans and non-Veterans. The baseline analysis did not include all possible elements of X_i, due to their potential endogeneity with Veteran status (the baseline analysis included an indicator of urban residential location [residence in a metropolitan statistical area]), but we considered an extended model that included these additional characteristics as sensitivity analyses in Appendix C.3.1.

This general approach was applied to MEPS, NHIS, and BRFSS to assess the robustness of the findings. NHIS and BRFSS have larger sample sizes but measure fewer health conditions than MEPS. BRFSS was also used to examine differences in health behaviors (e.g., smoking) and other health indicators (e.g., obesity) between Veterans and non-Veterans.

C.1.5.2 Current Differences in the Prevalence of Health Conditions between VA Patients and Non-VA Patients

The analyses comparing VA patients to non-VA patients followed the same structure as the analyses comparing Veterans to non-Veterans (C.1.5.1).

Differences in the prevalence of health conditions between VA patients and non-VA patients can be summarized by comparing observed prevalence rates between the two groups. Any observed differences in prevalence provide insight that the two populations are different. However, the demographic composition of VA patients differs from that of non-VA patients,

---

and any observed differences in prevalence may be attributable to these demographic differences. For a complete summary of the demographic differences between VA patients and non-VA patients, see Table C-18.

In order to adjust for the different demographic compositions of VA patients and non-VA patients, we calculated adjusted prevalence rates. An adjusted prevalence uses a model to predict the prevalence of a health condition for a reference population. This is achieved by predicting the prevalence of a health condition for a set of observations that has the same demographic composition as the population of interest. For the analyses of this section, the population of interest is the Veteran population. Thus, the adjusted prevalence for VA patients estimates the prevalence among VA patients if their demographic composition matched the demographic composition of all Veterans, and the adjusted prevalence for non-VA patients estimates the prevalence among non-VA patients if their demographic composition matched the demographic composition of all Veterans.

All comparisons made between VA patients and non-VA patients using adjusted prevalence rates account for the different demographic composition of the two populations. Therefore, any remaining differences after adjustment can be attributed to factors other than demographics. If large differences remain, this suggests that the VA patient population differs from that of the general Veteran population.

Calculating adjusted prevalence rates for VA patients and non-VA patients requires a model that predicts the prevalence of health conditions by VA patient status and other demographics. We used the following notation:

1. *i* represents an individual captured in the survey or administrative data of interest.

2. H_i =1 denotes the presence of a health condition or behavior of interest as identified by relevant ICD-9 or by self-report, and H_i = 0 if the condition is absent.

3. VA_i indicates whether the individual is a VA patient (VA_i = 1 for VA patients and VA_i = 0 otherwise).

4. Z_i is a vector of mutually exclusive demographic and geographic indicator variables defined by individual geographic location (either Census Region [Northeast, Midwest, South and Midwest] or state), age category (5 or 10 year intervals), sex, and race/ethnicity. Service cohort is not available in MEPS, which is the principal data source for this analysis; the effect of particular service cohorts can only be indirectly approximated by determining how differences between Veterans and non-Veterans vary with age.

5. X_i is a vector of individual characteristics that are associated with health conditions that may be associated with differences in disease, including whether the individual lives in an urban location, marital status, education, employment/student status, smoking, and health insurance coverage.

We chose to use logistic regression models at the individual level of the form:

$$(4) \quad logit(Pr[H_i = 1]) = \alpha + \gamma_1 VA_i + \gamma_2 Z_i + \gamma_3 VA_i * Z_i + X_i \beta + f(\tau_i)$$

where τ_i is the calendar year of observation i, and $f(\tau_i)$ is some function of time (e.g., a spline function or a set of year indicators). The function $f(\tau_i)$ accounts for any time trends in the prevalence of health conditions across the entire Veteran population. The interaction term $(\gamma_3 VA_i * Z_i)$ allows differences in prevalence between VA patients and non-VA patients to vary by demographic characteristics.

Let $\hat{h}_2(VA_i, Z_i, X_i, \tau_i) = expit(\hat{\alpha} + \hat{\gamma}_1 VA_i + \hat{\gamma}_2 Z_i + \hat{\gamma}_3 VA_i * Z_i + X_i\hat{\beta} + \hat{f}(\tau_i))$ be the estimated prevalence for an observation in year τ_i with demographics Z_i, VA patient status VA_i, and covariates X_i. The VA patient adjusted prevalence for year τ in demographic group Z is given by:

$$p_{VA}^{adj} = \frac{1}{N_{vet}} \sum_{i:\, Z_i = Z} w_i \, \hat{h}_2(1, Z, X_i, \tau)$$

where w_i is the survey weight and $N_{vet} = \sum_{i:\, Z_i = Z} w_i$. This amounts to a weighted average of estimated prevalences among all Veterans with demographics Z, where the estimated prevalence is evaluated for $VA = 1$ in year τ. In other words, we estimate the prevalence of a health condition among all Veterans with specific demographics as if they all were VA patients. The adjusted prevalence for non-VA patients in year τ and demographic group Z is given by:

$$p_{non-VA}^{adj} = \frac{1}{N_{vet}} \sum_{i:\, Z_i = Z} w_i \, \hat{h}_2(0, Z, X_i, \tau)$$

where everything is as before. Note that the only difference between the VA patient and non-VA patient adjusted prevalence is that the VA patient adjusted prevalence sets the VA patient status to 1 for all observations, and the non-VA patient adjusted prevalence sets the VA patient status to 0 for all observations.

We used MEPS as the primary data source for this analysis because it identifies a broad set of diagnosed health conditions and the use of VA health care services, which is used to identify VA patients.

C.1.5.3 Projecting Future Prevalence among Veterans

Projections of the future prevalence (and counts) of key health conditions among Veterans were undertaken in three main steps. First, the Veteran population was projected forward by demographic groups in Section 3. Second, the prevalence of key health conditions were projected forward by demographic groups using the models of C.1.5.1 (details below). Finally, the number of Veterans in each demographic group was multiplied by the corresponding prevalence to get the projected number of Veterans with a particular health condition from 2015 to 2024.

C.1.5.1 focuses on the current prevalence of health conditions among Veterans. Assuming that the prevalence of key health conditions is static across the next decade within demographic groups (a strong assumption), the number of Veterans with specific health conditions can be estimated by multiplying these static prevalence rates by the population projections from Section 3 (all within demographic groups). Any changes in the overall prevalence of a health

condition using this approach can be attributed to the changing demographic composition of Veterans because the demographic-specific prevalence rates are assumed to remain constant.

Assuming constant demographic-specific prevalence rates is a strong assumption and not expected to hold. The model given by (1) accounts for any time trends in the prevalence of health conditions through the inclusion of $f(\tau_i)$. Therefore, these models can be used to project forward the demographic-specific prevalence rates while accounting for trends over time. Recall, τ_i is the calendar year of observation. By setting τ_i to a future year and estimating the adjusted prevalence given in equation (3), the projected demographic-specific prevalence is obtained. For example, suppose we want to estimate the prevalence in 2020. We simply set $\tau = 2020$ in equation (3):

$$p_{vet}^{adj}(Z, 2020) = \frac{1}{N_{vet}} \sum_{i: Vet_i=1 \ \& \ Z_i=Z} w_i \, \hat{h}_1(1, Z, X_i, 2020)$$

These demographic-specific prevalence projections are multiplied by the Veteran population projections of Section 3 to obtain the projected number of Veterans with specific health conditions.

These baseline results were adjusted for likely service-connected conditions. First, the estimated prevalence rates for 2014 were fixed for each birth-year based cohort and carried forward over the projection period (2015–2024). This assumes that the prevalence of PTSD is not related to age, but instead, related to birth cohort. This allows us to use age to indirectly control for service during times of war, such as Vietnam. Specifically, the cohort that was born in 1980 has the same prevalence of PTSD in 2014 at age 34 as they would in 2024 at age 44. Second, prevalence estimates of newly separated Veterans were estimated using MHS encounter data. Finally, we allow for recovery from these conditions. This approach captures the more relevant trends in service-connected health conditions. The details of this adjustment are in Appendix C.1.5.5.

C.1.5.4 Projecting Future Prevalence among VA Patients

Projections of the future prevalence (and counts) of key health conditions among VA patients were undertaken in four main steps. First, the Veteran population was projected forward by demographic groups in Section 3. Second, the number of VA patients were projected forward by demographic groups in Section 4. Third, the prevalence of key health conditions were projected forward by demographic groups using a modification of the models of C.1.5.2 (details below). Finally, the number of VA patients in each demographic group was multiplied by the corresponding prevalence to get the projected number of VA patients with a particular health condition from 2015 to 2024.

C.1.5.2 focuses on the current prevalence of health conditions among VA patients. Assuming that the prevalence of key health conditions is static across the next decade within demographic groups (a strong assumption), the number of VA patients with specific health conditions can be estimated by multiplying these static prevalence rates by the VA patient population projections from above (all within demographic groups). Any changes in the overall prevalence of a health condition using this approach can be attributed to the changing

---

demographic composition of the VA patient population because the demographic-specific prevalence rates are assumed to remain constant.

Assuming constant demographic-specific prevalence rates is a strong assumption and not expected to hold. The model given by equation (4) accounts for any time trends in the prevalence of health conditions through the inclusion of $f(\tau_i)$. Therefore, these models can be used to project forward the demographic-specific prevalence rates of health conditions among VA patients while accounting for trends over time. However, in order to estimate a time trend that is consistent with our estimates for the Veteran population as a whole and to improve the precision of the trend estimate, we modified equation (4) to include an indicator for being a Veteran and to include non-Veterans in the prevalence estimation. Analogous to the Veteran case, we projected the demographic-specific prevalence among VA patients by the calendar year of observation, τ_i, to a future year and estimating the prevalence given by the modified equation (4). These demographic-specific prevalence projections were multiplied by the VA patient population projections to obtain the projected number of VA patients with specific health conditions. We generate projections using prevalence estimates from MEPS and from VA encounter data. In each case, the approach is the same.[63] However, the interpretation is different. The MEPS results predict the prevalence of health conditions among VA patients, regardless of whether treatment for the specific condition is received at VA, whereas the VA encounter analysis predicts the prevalence of health conditions treated by VA among VA patients.

We also adjust these baseline projections for service-connected conditions using the same approach described in Appendix C.1.5.5

C.1.5.5 Projecting Future Prevalence of Service-Connected Conditions

TBI, PTSD, and other mental health conditions are connected to deployment and combat exposure (Ramchand et al., 2015). Given that TBI and PTSD are caused by specific trauma and have relatively low prevalence rates in the non-Veteran population, it is likely that these conditions are predominantly determined by military experience, rather than age, among the Veteran population. The umbrella measure of "any mental health condition" includes PTSD and other conditions that may be linked to deployment to a combat zone, so we consider it to be linked to military service rather than age for the projections.

We account for this relationship by using a birthyear-based cohort approach to project the prevalence of prevalence of TBI, PTSD, and mental health conditions for Veterans and VA patients. The future prevalence of each condition is projected separately for Veterans who separated from service before 2015 ("Pre-2015 Veterans") and for future Veterans who will separate from service in 2015–2024 ("Post-2014 Veterans").

Pre-2015 Veterans (VA patients) – The estimated prevalence of each condition among Veterans in 2014 is held constant within cohorts, defined by birthyear, as the population ages. For

---

[63] For the projections using VA encounter data, equation (4) was estimated without modification because this data only includes Veterans.

example, the prevalence of PTSD among Veterans who were born in 1994 was 11 percent when they turned 20 years old in 2014. We assumed that the prevalence of PTSD will remain constant in these Veterans as they age, so that when they turn 30 years old in 2024, the prevalence of PTSD is 11 percent. PTSD may improve with treatment, in which case this assumption of constant prevalence within cohort would cause us to overestimate the prevalence of PTSD among Veterans and VA patients. However, research findings suggest that the highest rate of remission is within the first year post-diagnosis[64] and Veterans who separated from service before 2015 are one or more years post-service in the projection years (2015–2024). Further, the overall profile of remission is not well-documented and our data do not include information about when Veterans experienced the traumatic events, so we do not adjust for remission among this group. The projected prevalence is demographic-specific, so the overall prevalence for a birthyear cohort will change over time if the demographic composition of the cohort changes through mortality or VA use along non-age dimensions (e.g. sex).

Post-2014 Veterans (VA patients) – The implicit assumption in the projections of non–service-connected chronic conditions, such as hypertension and diabetes, is that the prevalence rate among new Veterans is the same as the prevalence rate among existing Veterans with the same demographic characteristics (e.g., age and sex). We cannot make this assumption in the case of service-connected conditions; therefore, we must assume a future prevalence rate for each health condition among new Veterans. Our underlying assumption is that there will be no future conflicts during the ten-year projection period, so new Veterans will have less exposure to combat and thus lower prevalence of TBI, PTSD, and mental health conditions. The prevalence rates we assume for the projections are derived from our analysis of MHS encounter data and from the existing research on the relationship between these health conditions and deployment. We also allow for recovery or remission of the health conditions in the first year post-separation for Veterans and post-enrollment for VA patients. The assumed prevalence and remission rates are discussed in detail below.

Estimation – The projections of the prevalence of PTSD (and mental health conditions) among Veterans and VA patients are based on the 2014 demographic-specific prevalence estimates from MEPS. The projections of the prevalence of TBI among VA patients are based on the 2014 demographic-specific prevalence estimates from VA encounter data. VA encounter data reflect the health conditions of VA patients only, so we project the prevalence of this condition for VA

---

[64] Based on a literature review, Tanielian and Jaycox (2008) suggest that the three-month remission rate of PTSD is 30–40 percent depending on type of treatment, but the probability of relapse is unknown. A review of longitudinal PTSD studies by Santiago et al. (2013) indicates that approximately 40 percent of PTSD cases remit after one year. A recent literature review and meta-analysis by Morina et al. (2014) found that 44 percent of PTSD cases were non-cases at follow-up (mean 40 months). A report by the Congressional Budget Office (2012) found that of VA patients initially diagnosed with PTSD, 75–80 percent of those who continue to use VA health services receive treatment for PTSD in the four years following diagnosis. This estimate conflates the PTSD remission rate and non-random exit from the VA health system, i.e., those who no longer need services for PTSD may drop out of the VA patient sample, but is likely a better representation of the prevalence among VA patients. Frieden and Collins (2013) find that approximately 77 percent of new TBI cases do not require treatment for more than one year post-injury.

---

patients only. All projections are made using demographic-group level data, but we abstract from this in the following discussion for simplicity.

The projected prevalence of health condition *HC* among Veterans in year *t* is the weighted average of the prevalence among the Pre-2015 Veterans in each birthyear cohort and the prevalence among the Post-2014 Veterans in each birthyear cohort. This is given by

$$p_{c,t}^{HC} = \left(1 - f_{c,t}^{post\ sep}\right) \times p_{c,2014}^{HC} + f_{c,t}^{new\ sep} \times p_{assumed}^{HC\ initial}$$
$$+ f_{c,t}^{(post\ sep - new\ sep)} \times p_{assumed}^{HC\ chronic}$$

where $f_{c,t}^{post\ sep}$ is the fraction Veterans in year *t* who were born in year *c* and who separated from service after 2014, $p_{c,2014}^{HC}$ is the prevalence of the health condition *HC* among Veterans who separated before 2015, and $p_{assumed}^{HC}$ is the prevalence rate that is assumed for Veterans who separated after 2014.

The first term is the prevalence of *HC* among Veterans who separated from service before 2015, $p_{c,2014}^{HC}$, weighted by the fraction of Veterans separated before 2015, $(1 - f_{c,t}^{post\ sep})$. The second term is the initial prevalence of *HC* among those who separated after 2014, $p_{assumed}^{HC\ initial}$, weighted by the fraction of Veterans who separated in year *t*, $f_{c,t}^{new\ sep}$. The third term is the prevalence of *HC* requiring more than one year of treatment, $p_{assumed}^{HC\ chronic}$, weighted by the fraction of Veterans who separated from service after 2014 but before year *t*, $f_{c,t}^{(post\ sep - new\ sep)}$, where $p_{assumed}^{HC\ chronic}$ is equal to $p_{assumed}^{HC\ initial}$ times the fraction of *HC* cases who require ongoing treatment.

We follow the same approach for VA patients with one exception. The prevalence rate and remission probability of the health conditions for future VA patients is determined by the year in which the Veteran enrolled in VA rather than by year of separation from service. That is, we split future Veterans into two groups: Veterans who were VA patients in 2014 and those who were not (post-2014 VA patients). The group of post-2014 VA patients includes all Veterans who separated post-2015 and also includes new VA patients who separated before 2015. This date is more relevant than the separation date for VA patients under the assumption that new VA patients who did not immediately enroll in VA post-separation are less likely to have a service-connected *HC* than those who began using VA health care services right away. We make the following assumptions regarding prevalence and remission rates for the estimation.

- The prevalence of PTSD among new Veterans in 2015–2024 is 5.4 percent. This prevalence rate, estimated using MHS data, is the average of the annual prevalence rates of PTSD among service members separating 2009–2014. It is a little lower than the estimated prevalence of 7.9 percent among OEF/OIF-era Veterans who did not deploy and do not use VA in Dursa et al. (2014). The MHS estimate may overstate the prevalence of PTSD among new Veterans in 2015–2024, because only two-thirds as many of them will have deployed to Iraq or Afghanistan. However, the MHS estimate may be lower than the actual rate of PTSD if service members are reluctant to seek

diagnosis and treatment for PTSD before separation, but seek care after. In addition, as discussed above, due to data limitations and lack of consensus in the literature regarding the profile of remission and relapse of these conditions, we do not formally adjust the prevalence to account for this, which may lead to projections that are too high.

- The prevalence of PTSD among new VA patients in 2015–2024 is 17.3 percent. Veterans with service-connected conditions are more likely to use VA. We estimated the prevalence ratio of PTSD among VA patients relative to all Veterans as the ratio between the prevalence of PTSD among VA patients under age 35 in 2014 (VA encounter data) and the prevalence of PTSD among separating service members under age 35 in 2012–2013 (MHS encounter data). We then inflate the assumed prevalence of 5.4 percent for all Veterans by this ratio (3.2). This resulting PTSD prevalence estimate for new VA patients is very close to the 17.5 percent prevalence rate of PTSD among VA patients who served post-2001 and who did not deploy to Iraq and Afghanistan estimated by Dursa et al. (2014).

- The one-year remission rate of PTSD is 35 percent for all Veterans and 30 percent for VA patients. A review of the literature suggests that the rate of remission in one year is 30–45 percent (Tanielian and Jaycox, 2008; Santiago et al., 2013; Morina et al., 2014), so we choose a middle value for the projections with all Veterans. However, a report by the Congressional Budget Office (2012) found that, of VA patients initially diagnosed with PTSD, 75–80 percent of those that continue to use VA health services receive treatment for PTSD in the four years following diagnosis. This suggests that PTSD among VA patients may be more difficult to treat, motivating us to choose a lower rate of remission for this population.

- The prevalence of mental health conditions among new Veterans in 2015–2024 is 32.5 percent. This is estimated using MHS encounter data following the approach we use for PTSD.

- The prevalence of mental health conditions among new VA patients in 2015–2024 is 48.8 percent. This was estimated from MHS and VA encounter data following the approach for PTSD.

- The one-year remission rate for mental health conditions is 6.3 percent for all Veterans and 10 percent for VA patients. The umbrella of mental health conditions includes a host of conditions, making it difficult to choose an appropriate overall remission rate for the condition, as it depends on how well each condition responds to treatment and the fraction of Veterans with each condition. However, mental health conditions include PTSD, so to be consistent with the remission rate assumed for PTSD, we apply the same rate to mental health, scaled by the fraction of Veterans with mental health conditions that have PTSD. Using 2014 MHS data, we find that 18 percent of newly separated Veterans with mental health conditions have PTSD. Therefore, we assume a 6.3 percent (=0.18*0.35) one-year remission rate for mental health conditions among all Veterans. Similarly, we assume a scaled PTSD remission rate for mental health conditions among VA patients. Using VA encounter data, we find that about one-third of VA patients with any mental health condition have PTSD, so we assume a 10 percent rate (=1/3 *30%) for

---

mental health conditions among VA patients. As Veterans can also recover from other mental health conditions, this is likely an underestimate of the recovery rate.

- The prevalence of TBI among new VA patients in each year 2015–2024 is 0.5 percent. This assumed prevalence of TBI among new VA patients reflects our assumption of no future conflict during the next decade and is derived from a CDC report of the number of TBI-related emergency department visits among adults in the United States (Centers for Disease Control and Prevention, 2014c).[65] The prevalence of TBI among separating service members under the age of 35 in MHS encounters and the prevalence among VA patients under the age of 35 in VA encounter data are very similar, so no adjustments were made to the CDC rate to account for selective use of VA health care services.

- We assume that twenty percent of TBI cases among VA patients who are predicted to enroll in each year 2015–2024 require ongoing treatment. This is based on estimates from Frieden and Collins (2013).

- For all conditions—TBI, PTSD, and other mental health conditions—the probability of remission is assumed to be zero one or more years post-separation(enrollment). This assumption implies that the prevalence of health conditions among Veterans who separated before 2015 (and VA patients who enrolled in VA before 2015) is fixed for each birthyear cohort because these populations are already one year post-separation(enrollment) in the first projection year.

Limitations – The data we are using for the baseline estimates of prevalence (MEPS, VA encounter, and MHS) only captures conditions that are treated in each year. If Veterans do not require doctor visits each year treat an ongoing condition, we will underestimate the fraction of Veterans who require treatment for each condition.

The research on the prevalence of PTSD among Veterans who have not deployed is thin, making it challenging to estimate prevalence rates under the assumption of no future conflicts over the projection period. Dursa et al. (2014) and Hoge et al. (2004) are exceptions in a literature that focuses on service-connected conditions among Veterans who deployed. These two studies find an unexpectedly high rate of PTSD among OEF/OIF era Veterans who did not deploy and who are pre-deployment respectively. If these prevalence rates are too large, then our projections overstate the prevalence of PTSD among future Veterans.

The research on the course of remission for those with PTSD is also sparse. We aggregated the results of several literature review for our assumptions, but did not find a strong source documenting PTSD over the life course to use for this analysis. We are not able to sign the direction of the bias from our estimation assumptions because some Veterans will take longer than one year to remit (biasing our estimates upward) and some Veterans will relapse (biasing our estimates downward.

---

[65] This report indicates that there were 470 TBI-related emergency department visits per 100,000 adults age 25–44 years old in 2009–2010.

C.1.5.6   Upper and Lower Bounds for Projections

Computational limitations prevented us from calculating 95-percent prediction intervals for our projections. However, crude upper and lower bounds were estimated by calculating the 95-percent confidence intervals for the demographic-specific prevalence rates, and by performing the projections with the demographic-specific prevalence rates set to both the upper and lower bounds. Specifically, we multiplied the demographic-specific prevalence upper bounds (from the 95-percent confidence intervals) by the population projections, and used the resulting projections as an upper bound. Similarly, we multiplied the demographic-specific prevalence lower bounds (from the 95-percent confidence intervals) by the population projections, and used the resulting projections as a lower bound. These bounds are expected to be more conservative (wider) than actual 95-percent prediction intervals under this modeling framework because they ignore the correlation between the predicted prevalence rates across demographic groups. Other modeling strategies would have yielded different projections and different uncertainties associated with the projections. An alternative approach would have been to model the prevalence rates within demographic groups as a time series, which accounts for the correlation between prevalence within demographic groups across time.

C.2   Current Health Care Needs Prevalence Results

C.2.1   Prevalence for Veterans and Non-Veterans

Table C-6. Prevalence of Diagnosed Health Conditions for Veterans and non-Veterans

NOTES: *The difference in adjusted means is statistically different from zero at the 5 percent level (p-value<0.05). Sample size, non-Veterans = 150,225 and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. The unadjusted prevalence in results columns (1) and (2) are equivalent to the fraction of Veterans and non-Veterans who have been diagnosed with each condition. The adjusted prevalence in results columns (3) and (4) are the predicted prevalence from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, residential location in an MSA, and a nonlinear time trend. These estimates show the differences in prevalence of health conditions for Veterans and for non-Veterans with the same demographic profile as Veterans. Cancer includes any malignancy and mental health condition includes any mental health condition.

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Sample size, non-Veterans = 150,225 and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. Cells labeled IS indicate that the prevalence model for the specific health condition could not be estimated due to insufficient sample size. The adjusted prevalence estimates are the predicted prevalence from a logit estimation that included an indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, residential location in an MSA, and a nonlinear time trend. These estimated differences control for the demographic differences between Veterans and non-Veterans and within demographic subgroups. Cancer includes any malignancy, and Mental Health includes any mental health condition.

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Sample size, non-Veterans = 150,225 and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. *The difference in adjusted means is statistically different from zero at the 5 percent level (p-value<0.05). The unadjusted prevalence in results columns (1) and (2) are equivalent to the fraction of VA patients and Veterans not using VA health services that have been diagnosed with each condition. The adjusted prevalence in results columns (3) and (4) are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, residential location in an MSA, and a nonlinear time trend. These estimates show the differences in the prevalence of health conditions for VA patients and Veterans not using VA health services, both with the same demographic profile of the overall Veteran population.

Table C-14. Predicted Means of Disease Burden Measures Among, by VA Patient Status

	Adjusted Means (Std. Errors)		p-value for Difference in Adjusted Means
	VA Patients	Non-VA Patients	
Has 1+ IADLs	0.152	0.086	< 0.000
	(0.022)	(0.012)	
Charlson Comorbidity Index > 1	0.128	0.110	0.049
	(0.017)	(0.014)	
Charlson Comorbidity Index	0.153	0.135	0.132
	(0.022)	(0.019)	

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: N =11,251 for the total Veteran sample. Predicted or adjusted means were obtained from estimating logistic regressions with the following additional covariates included: sex (male is the omitted category), five race/ethnicity categories, 14 age categories, four Census regions, an MSA indicator, and year fixed effects using the margins command in Stata treating Veterans as though they had similar observable characteristics as civilians. The Charlson Comorbidity Index model was estimated using a Poisson regression.

Table C-15. Adjusted Means of Comorbid Mental Health Condition (Mental Health Condition + Another Condition/Limitation) for Veterans, by VA Patient Status

	Adjusted Means (Std. Errors)		p-value for Difference in Adjusted Means
	VA Patient	non-VA Patient	
Has any IADL + any Mental Health Condition	0.052 (0.004)	0.026 (0.003)	< 0.000
Has Any Condition + any Mental Health Condition	0.244 (0.009)	0.130 (0.006)	< 0.000
Has Any Charlson condition + any Mental Health Condition	0.022 (0.003)	0.015 (0.002)	0.048

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: N =12,313 for the total Veteran sample. Predicted or adjusted means were obtained from estimating logistic regressions with the following additional covariates included: sex (male is the omitted category), five race/ethnicity categories, 14 age categories, four Census regions, an MSA indicator, and year fixed effects using the margins command in Stata treating Veterans as though they had similar observable characteristics as civilians. The Charlson Comorbidity Index model was estimated using a Poisson regression.

SOURCE: RAND analysis of MEPS, 2006–2012.

Demographic Group	Adjusted Prevalence (Std. Errors)						
	Cancer	COPD	Diabetes	HBP	Hearing Loss	IHD	PTSD

NOTES: Sample size, non-VA patient Veterans = 7,442. Cells labeled IS indicate that the prevalence model for the specific health condition could not be estimated due to insufficient sample size. The adjusted prevalence estimates are the predicted prevalence from a logit estimation that included an indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, residential location in an MSA, and a nonlinear time trend. These estimated differences control for the demographic differences within demographic group. HBP is hypertension. * $p < 0.05$; ** $p < 0.01$.

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Columns (3) (Veterans, VA patients) and (4) (Veterans, non-VA patients) are two mutually exclusive categories of column (2) (Veterans). Sample size, Veterans = 12,313; sample size, non-Veterans = 150,225; sample size, VA patients = 4,871; sample size, non-VA patients = 7,442. MSA denotes residential location in a metropolitan statistical area (MSA).

C.2.5 Prevalence Estimates with MHS and VA Encounter Data and Reliance

Table C-19. The Prevalence of Health Conditions in VA Encounter Data

Health Condition	Prevalence
Mental health condition	32.1%
Hypertension	29.2%
Lipid disorders	22.2%
Diabetes	18.8%
Arthritis	18.2%
Musculoskeletal conditions	18.0%
Mood disorder	14.3%
IHD	12.3%
Benign prostate hypertrophy	11.0%
Dermatologic conditions	10.6%
PTSD	9.8%
Hearing loss	8.3%
Dental conditions	8.0%

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: **Bold** indicates p-value < 0.05 for the difference between VA reliant VA patients and VA patients who are not reliant on VA. Sample size, VA patients = 4,871. A VA patient is considered reliant if all medical expenses in the year were VA and family/self-paid. A VA patient is considered non-reliant if he or she has some medical expenses paid by a non-VA health insurance source. The adjusted prevalence rates are the predicted prevalence rates from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four Census regions, residential location in an MSA, and a nonlinear time trend. VA patient status is defined as having any expenditures paid by VA at the person, not condition, level.

Table C-22. The Prevalence of Health Conditions in MHS and VA Encounter Data for Veterans Younger than 35 Years Old

Health Condition	MHS encounter	VA encounter
Mental health conditions	37.67%	42.84%

SOURCE: RAND analysis of MHS encounter data (2012–2013) and VA encounter data (2014).

NOTES: Sample size, the number of separating military personnel aged less than 35 in MHS encounter data is 325,849, and the number of Veterans in VA encounter data aged less than 35 is 503,205.

C.3 Current Health Care Needs Sensitivity Analysis

C.3.1 Alternative Prevalence Models for Veterans and Non-Veterans

In this appendix, we describe our baseline specification (Model 1) and differences between the baseline specification and two alternative specifications (Models 2 and 3) that were used to assess the sensitivity of our findings to these baseline specifications.

- *Model 1* adjusts for a respondent's sex, age (14 age categories: 20-24, 25-30,…, 80-85, and 85+), race/ethnicity (five racial/ethnic categories: Hispanic, non-Hispanic White, non-Hispanic Black, non-Hispanic Asian, or Other/Multiple), four Census regions of residence (Northeast, Midwest, South, and West), an indicator for residence in an MSA, and a nonlinear time trend that adjusts for the year surveyed. The nonlinear time trend includes the following measures: (1) an indicator if the survey year was 2006, 2007, or after 2007; (2) a linear time trend for years after 2008 (e.g., equals 0 for 2006–2008, 1 for 2009, 2 for 2010, etc.).

- *Model 2* adds the following covariates to Model 1: education (four categories), interactions between sex and race/ethnicity, and indicators of health insurance coverage, marital status, student status, and employment status.

- *Model 3* replaces the nonlinear time trend in Model 1 with indicators for each calendar year.

In Table C-23, we present estimated prevalence of health conditions for Veterans and non-Veterans using these three model specifications. The results are quantitatively similar across all three models.

Table C-23. The Prevalence of Diagnosed Health Conditions for Veterans and Non-Veterans: Alternative Specifications

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Sample size, non-Veterans = 150,225 and sample size, Veterans = 12,313. Sample sizes may be smaller for some conditions due to missing values. The predicted prevalence rates are from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, and residential location in an MSA. Models 1 and 2 include a nonlinear time trend, while Model 3 includes indicators for each calendar year. Model 3 also includes indicators for 4 education categories, health insurance coverage, being married, being a student or in school, being employed, and interactions of sex and race/ethnicity. These estimates show the differences in prevalence of health conditions for Veterans and for non-Veterans with the same demographic profile as Veterans. Cancer includes any malignancy and mental health condition includes any mental health condition.

In Tables C-24, C-25, and C-26, we report the estimated odds ratios for the Model 2 control variables. These tables describe the association between each control variable and disease prevalence, while adjusting for the remaining Model 2 control variables. In general, these additional controls explain some of the variation in prevalence rates, but as shown in Table C-21, overall predicted prevalence rates based on Model 2 are similar to baseline estimates from Model 1.

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Model 2 included indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, residential location in an MSA, a nonlinear time trend, four education categories, health insurance coverage, being married, being a student or in school, being employed, and interactions of sex and race/ethnicity. These estimates show the relative change in odds of having been diagnosed or treated for the given condition under a given demographic characteristic. An odds ratio greater than (less than) 1 means that the probability increases (decreases). *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

C.3.2 Alternative Prevalence Models for Veterans by VA Patient Status

As reported in C-1, we conducted similar sensitivity tests for our analysis comparing Veterans by VA patient status. We again estimated Models 1-3 as described in C-1 for our analysis of Veterans only.

As shown in Table C-27, results are similar across the three models, though there is more variation in results across models in VA patient versus not-patient analyses than in the non-Veteran versus Veteran analysis. In Tables C-28, C-29, and C-30, we report the estimated odds ratios for the Model 2 control variables. These describe the association between each control variable and disease prevalence among Veterans, while adjusting for the remaining Model 2 control variables.

SOURCE: RAND analysis of MEPS, 2006–2012.

NOTES: Sample size, Veterans = 12,313. Cells labeled IS indicate that the prevalence model for the specific health condition could not be estimated due to insufficient sample size. The predicted prevalence rates are from a logit estimation that included indicators for sex, five race/ethnicity categories, 14 age categories, four census regions, and residential location in an MSA. Models 1 and 2 include a nonlinear time trend, while Model 3 includes indicators for each calendar year. Model 3 also includes indicators for four education categories, health insurance coverage, being married, being a student or in school, being employed, and interactions of sex and race/ethnicity. These estimates show the differences in prevalence of health conditions for VA patients and Veterans not using VA health services, both with the same demographic profile of the overall Veteran population. Cancer includes any malignancy and mental health condition includes any mental health condition.

SOURCE: RAND analysis of National Health Interview Survey (NHIS) (2006-2013).

NOTES: The unadjusted prevalence in results columns (1) and (2) are equivalent to the fraction of Veterans and non-Veterans who self-reported each condition. The adjusted prevalence in results columns (3) and (4) are the predicted prevalence from a logit estimation that included indicators for sex, five race/ethnicity categories, five age categories, four census regions, and a nonlinear time trend. These estimates show the differences in prevalence of self-reported health conditions for Veterans and for non-Veterans with the same demographic profile as Veterans. *The difference in adjusted means is statistically different from zero at the 5% level (p-value<0.05).

C.3.3.2   Veterans vs. Non-Veterans in BRFSS

In Table C-30, we provide estimates of the prevalence of self-reported health conditions and health behaviors for Veterans and non-Veterans, some of which overlap with the ICD-9-based health condition measures, using BRFSS (2013).

Table C-32. The Prevalence of Self-reported Health Outcomes for Veterans and Non-Veterans in BRFSS

SOURCE: RAND analysis of Behavioral Risk Factor Surveillance Survey (BRFSS) (2013).

NOTES: ^ These conditions do not directly map to the ICD-9 based definitions in MEPS. The unadjusted prevalence in results columns (1) and (2) are equivalent to the fraction of Veterans and non-Veterans who self-reported each condition or behavior. The adjusted prevalence in results columns (3) and (4) are the predicted prevalence from a logit estimation that included indicators for sex, five race/ethnicity categories, five age categories, four census regions. These estimates show the differences in prevalence of self-reported health conditions for Veterans and for non-Veterans with the same demographic profile as Veterans. *The difference in adjusted means is statistically different from zero at the 5% level (p-value<0.05).

C.4 Projections of Future Health Care Needs

C.4.1 Projections for Veterans

C.4.1.1 Asthma

Table C-33. Projected Prevalence of Diagnosed Asthma Among Veterans by Sex, 2014–2024

C.4.4.8   Musculoskeletal Conditions with Chronic Pain Among VA Patients

Table C-104. Projected Prevalence of Diagnosed Musculoskeletal Conditions Associated with Chronic Pain Among VA Patients, 2015–2024

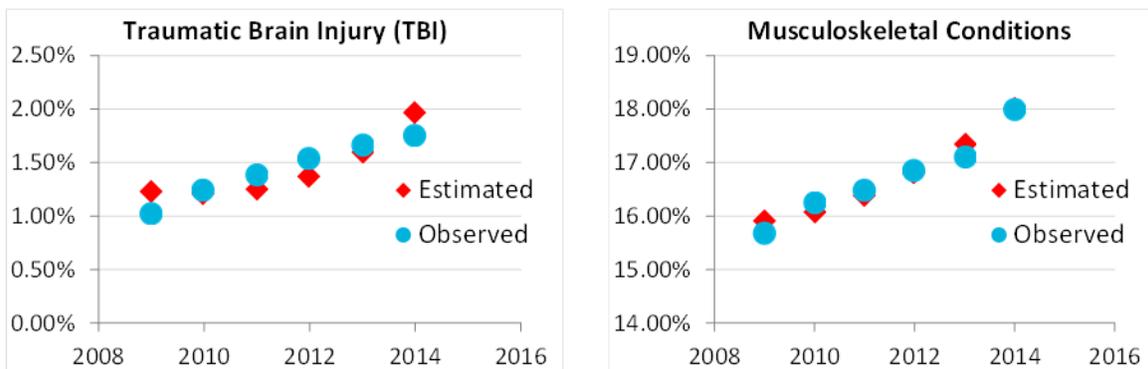
Year	Total	
	Count	Prevalence
2015	1,106,000	18.5%
2016	1,167,000	19.3%
2017	1,230,000	20.1%
2018	1,294,000	21.1%
2019	1,361,000	22.1%
2020	1,427,000	23.2%
2021	1,493,000	24.3%
2022	1,558,000	25.5%
2023	1,621,000	26.6%
2024	1,681,000	27.7%

SOURCE: RAND analysis of DoD, Census, VA, and VA encounter data.

C.4.5 Predicted Prevalence using VA Encounter Data: Goodness of Fit

In this section, we provide additional detail about the models we use to predict the prevalence of TBI and musculoskeletal conditions. Predicted prevalence is based on projecting observed information forward, based on logistic regression models fit to VA encounter data. The model is the similar to that used to estimate prevalence with MEPS (model 4 in Appendix C.1.5.2). Our model describes prevalence as a function of Veteran age, sex, and state of residence, and also includes a continuous time effect that captures observed changes in prevalence that go beyond changes expected because of changes in population demographics. These secular changes capture cohort effects that are related to Veteran combat experience. Including these secular trends is important for accurate estimation of demographic effects that are used to project trends forward based on changing demographic characteristics in the projected VA patient population.

The accuracy of predictions, by their very nature, is unknown. However, we can examine how closely our model is able to capture observed trends. Close prediction of observed prevalence rates provides reassurance that our predictions are reasonable. As shown in Figure C-1, our models provided a good fit to the observed prevalence rates and trends. TBI is relatively rare, and at the scale shown, the curvature from the logistic regression fit is evident. However, this reflects very small differences between the observed and estimated prevalence. In 2014, we estimate 1.97 percent TBI prevalence and observe 1.75 percent prevalence, a 0.22 percentage point difference. Estimated prevalence was very close to observed values musculoskeletal conditions. In 2014, we estimate 18.01 percent prevalence of musculoskeletal conditions and observe 17.99 percent prevalence, a 0.02 percentage point difference.

Figure C-1. Predicted Prevalence Goodness of Fit


SOURCE: RAND analysis of VA encounter data (2009–2014).

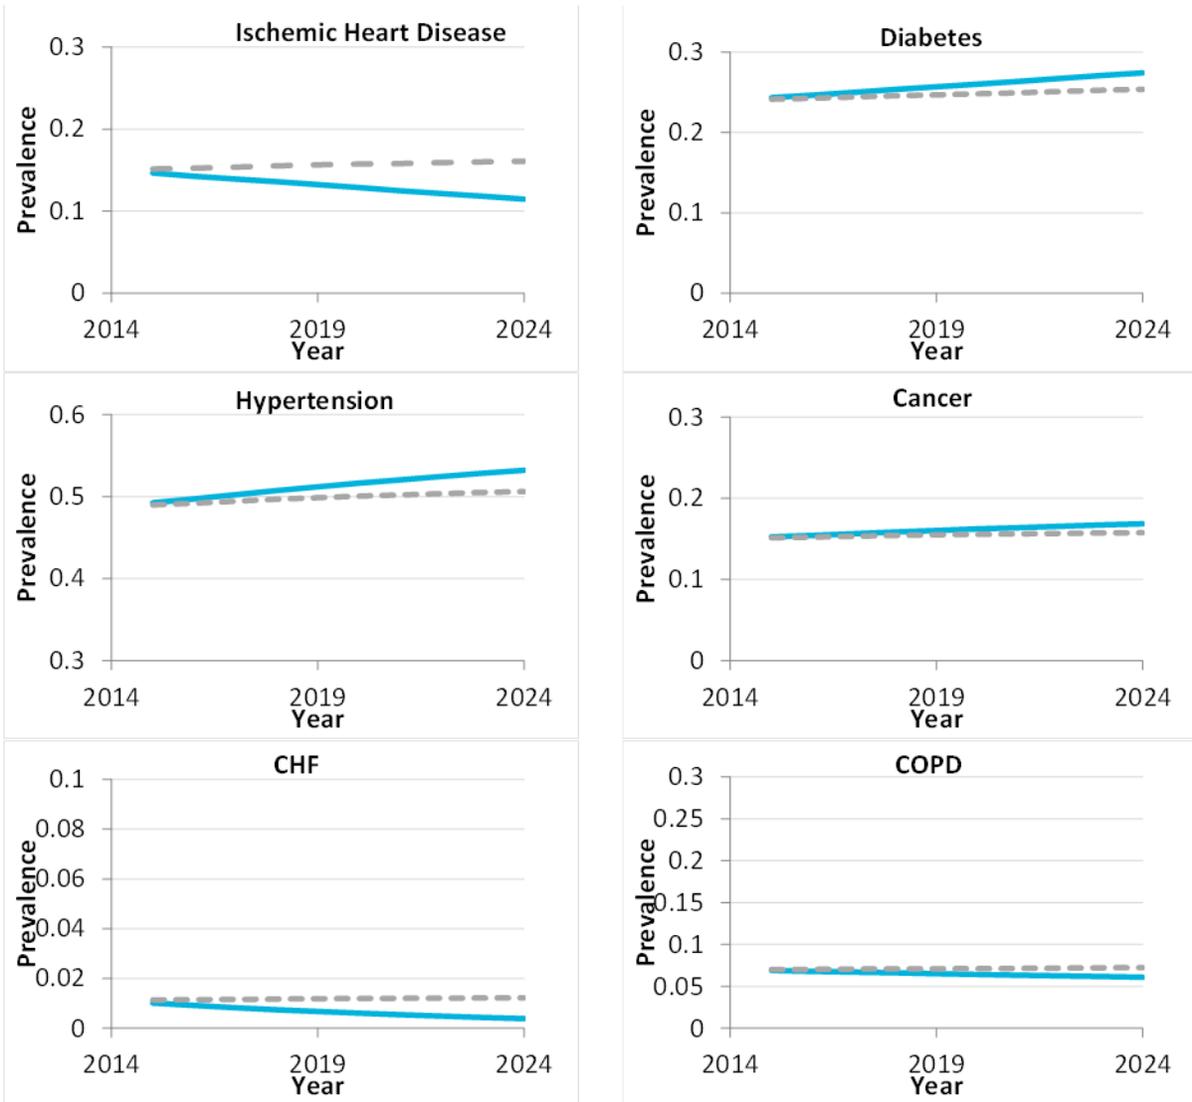
C.4.6 Sensitivity Analyses for Prevalence Projections

Future prevalence often follows demographic trends because aging is a risk factor for many chronic conditions, including IHD. For example, several studies have projected increases in the prevalence of IHD in the overall U.S. population; this result follows from combining static estimates of IHD prevalence with future expected aging (Heidenreich et al., 2011). Similarly, we project that the aging trend for the VA patient population over this period (a one-year

projected increase in mean age—see Section 3) will tend to increase the prevalence of IHD and other chronic conditions. However, prevalence trends often also depend on trends in other risk factors; for example, factors known to affect IHD prevalence (in addition to aging) include smoking, obesity, and usage of preventive medications such as aspirin. Decreases in the incidence of AMI suggest that better treatment and improved risk factor control have reduced the incidence of acute IHD, and may also mitigate or outweigh future increases in chronic acute IHD due to aging. A projection model that solely relies on aging to project future changes would miss such trends.

To better model future prevalence, we developed models that incorporated a nonlinear trend to account for unobservable trends in risk factors. (Data limitations precluded the use of more complex modeling.) The disadvantage of this approach is that a strictly linear trend may not be appropriate, and may exaggerate true changes when extrapolated for longer periods. For example, in projecting the prevalence of CHF, the decreases in prevalence that were evident in MEPS in 2008–2012 translated into unrealistically sharp projected declines during 2015–2024.

To better demonstrate how our assumptions affect projections, we show projections that incorporate a linear trend in prevalence (solid blue lines) alongside "static" projections (dashed gray lines), in which future prevalence rates only reflect aging (Figure C-2). In most cases, the differences between the two projections were not large. However, the projected decline in the prevalence of IHD and CHF among Veterans are clearly attributable to the estimated time trend in the prevalence projections, rather than changes in the demographic composition of the population. As discussed above (Section 5), the trends do have relatively wide confidence intervals, which suggests that there is significant uncertainty regarding the magnitude of these declines.

Figure C-2. Veteran Prevalence Projections with and without Time Trends for Common Chronic Conditions


Appendix D   Scenario Development and Evaluation

D.1   Detailed Scenario Evaluation Methods

D.1.1   Changes to VHA Eligibility by Priority Group

D.1.1.1   Priority Group Sorting Algorithm

This section developed an algorithm to sort Veterans in the 2013 ACS Public-Use Microdata Sample (see Section 2.6 for a description of these data) into the VA priority groups. Priority groups determine whether a Veteran is eligible for health services and whether that Veteran will pay copays. All Veterans discharged as Honorable, General, or Uncharacterized and who satisfy the two-year length of service requirement (unless this requirement is waived) are eligible for assignment to one of these priority groups, but eligibility for health services is limited to Veterans in priority groups 1 through 8d. Currently, Veterans in priority groups 8e and 8g and not eligible to use VA services (although those in 8e are eligible for VA services related specifically to their service connected conditions).

Testing the scenarios described above requires not just measures of currently VA enrollees or VA users, but the entire population of Veterans and the corresponding priority group they would be assigned if they were enrolled. Therefore, we construct an algorithm to sort the entire Veteran population in the 2013 ACS PUMS into respective priority groups. We validate this sorting algorithm by comparing the subpopulation of Veterans reporting VA use with the corresponding subpopulation in VA administrative records, demonstrating a close fit. We then implement the scenarios described above, measuring the changes in priority group eligibility and estimating resulting VA users.

Before the algorithm begins, the ACS counts of Veterans are inflated to provide an overall count of the Veteran population in alignment with the RAND model described in the demography section (i.e., 21.9 million Veterans in 2013). The undercounting in the ACS arises from two sources: misreporting by respondents and limitation of the ACS in reaching individuals not living in housing units or group quarters. To address this undercounting, separate Veteran counts were calculated for cells defined by state, age band, sex, and race/ethnicity, then the frequency weights in the corresponding 2013 ACS PUMS cells were inflated to match these counts. Because the VA user counts in the ACS closely match administrative records, VA users were excluded from this process, so only non-patient Veteran cells had their weights inflated to match RAND model cells.

The sorting algorithm then proceeds in two broad steps:

1. Using the information available in the ACS on disability rating, household income, family size, and area of residence, it sequentially sorts Veterans into different priority groups, starting with the highest priority (priority group 1) and proceeding to priority group 5, sorting Veterans previously unassigned into higher groups into a given priority group based on qualifying factors. For example, an individual with service-connected disability rating of 100 percent (entitling this Veteran to priority group 1) and income below the National Means Test (entitling this Veteran to priority group 5) is first classified as priority group 1, and by the time the algorithm is assigning individuals priority group 5 status, he is already assigned to priority group 1, so he is not reassigned to priority group 5. At each stage, the pool of Veterans eligible to be assigned to priority group under consideration excludes any Veterans already assigned to a higher priority.

2. After this first-round set of assignments is carried out, the algorithm then reassigns the remaining Veterans who report use of VA to priority groups 1-5 in accordance with various

actuarial adjustments to reflect actual differences in VA patient counts. The algorithm then assigns priority groups 6-8 status to the remaining Veterans, using both self-reported data and actuarial adjustments. These actuarial adjustments are required for two reasons: item nonresponse or misresponse in fields vital to accurate priority group classification (e.g., service-connected disability ratings), and a lack of elicitations of criteria used by VA (e.g., date of initial enrollment, exact dates of service, possible exposure during service that qualifies Veterans for priority group 6 status). Finally, all Veterans unassigned at this stage who report being VA enrollees are assigned to priority group 8 status.

The ACS directly asks individuals their service-connected disability rating, allowing separate answers for 0 percent, 10–20 percent, 30–40 percent, 50–60 percent, and 70–100 percent. 50 percent or above entitles Veterans to priority group 1; 30–40 percent entitles Veterans to priority group 2; and 10–20 percent entitles Veterans to priority group 3. The algorithm therefore assigns these Veterans accordingly.

Priority group 4—the catastrophically disabled and/or housebound—are assigned based on the presence of ambulatory, independent living, or self-care difficulty, or report a disability or receipt of a disability benefit (Social Security Income or SSDI) *and* household income that falls below the VA housebound threshold.

Priority group 5 eligibility is assigned if any of three criteria are met: the Veteran reports Medicaid coverage; the Veteran reports Social Security Income receipt (which carries with it Medicaid eligibility); or the Veteran's household satisfies the National Income Test, given how many dependents the Veteran has.

However, the count of VA patients in priority group 5 is substantially lower than the actual priority group 5 patients in 2013 from VA administrative records. This deviation may arise from a number of sources, be they non-response or misreporting of household income (or differences in how this income would be deemed by VA); to correct for this deviation, unassigned Veterans who report being VA users are sorted in ascending order according to household income and are sequentially assigned priority group 5 status until the ratio of priority group 5 users to overall VA users agrees with 2013 VA administrative records.

Priority group 6 status is assigned among the remaining Veterans according to service era (inclusively between Vietnam Era to 8/2001) or report a 0 percent service-connected disability. The resulting priority group 6 size is substantially larger than in VA administrative records, since the true qualifying criteria for priority group 6 is a strict subset of these parameters (e.g., the 0 percent service-connected rating must be compensable). The number of priority group 6 VA users is correspondingly reduced (randomly) such that the ratio of priority group 6 users to priority group 5 users in the ACS mirrors that observed in VA administrative records.

However, there remain a substantial portion of potentially eligible VA non-users assigned priority group 6 status; this population is randomly reduced to agree with the ratio of projected eligible priority group 6 Veterans to potentially eligible priority group 5 VA users from the EHCPM model.

Priority group 7 status is assigned according to whether a currently unassigned Veteran satisfies the higher threshold of the National Income Test or the GMT for the number of dependents in that household and the area of residence. Although the ACS provides information on each

respondent's PUMA, the GMT is assessed at the county level. We reconcile these differences by assigning individuals in MSAs the corresponding GMT (for which there is no disconnect) and use the remaining state-level averages of non-MSA counties as the GMT for individuals residing in non-MSA PUMAs in that state.

The algorithm then revisits priority groups 1 through 3, which have previously been undercounted when comparing to VA administrative records. To rectify this issue, a logit model is fit to the likelihood of being previously assigned priority group 1 status (i.e., having reported a service-connected disability rating of at least 50 percent), where predictors include age, family size, race, ethnicity, family income, and era of service. Veterans who report being a VA user but who have not yet been assigned a priority group are then given a predicted probability of being priority group 1 using this logit model and their personal characteristics. They are then sequentially reassigned to priority group 1 by descending order of this probability (i.e., those most likely to be priority group 1 given their characteristics are the first to be assigned priority group 1) until the ratio of priority group 1 VA users to total VA users agrees with VA administrative records. This procedure is repeated sequentially for priority groups 2 and 3 on previously unassigned VA users.

Next, the count of VA patients in priority group 7 is substantially lower than the actual priority group 7 patients in 2013 from VA administrative records. This deviation may arise from a number of sources, be they nonresponse or misreporting of household income (or differences in how this income would be deemed by VA). To correct for this deviation, unassigned Veterans who report being VA users are sorted in ascending order according to household income and are sequentially assigned priority group 7 status until the ratio of priority group 7 users to overall VA users agrees with 2013 VA administrative records. A similar procedure is performed on VA non-users by ascending family income until the ratio of priority group 7 eligible Veterans to priority group 7 VA users matches Vet Pop Proxy predicted values.

Priority group 8b/8d is determined by assigning all remaining Veterans with household income under their GMT+10 percent (see priority group 7 calculation for a discussion of how GMT is determined) for their dependent class to this set of groups. Priority group 8a/8c is assigned to all Veterans reporting being VA users who are not otherwise assigned to a priority group and who do not report a 0 percent service-connected disability rating. Priority group 8e status is assigned to Veterans otherwise unassigned reporting being VA users and report a 0 percent service-connected disability rating.

Priority group 8g status is then assigned to all previously unassigned Veterans. However, this group is reduced by the exclusion of two classes of Veterans: Veterans who were discharged as "Other-than-honorable," "Bad conduct," or "Dishonorably." These discharge categories render the Veteran in question ineligible for VA health services. According to the Defense Department, 5.6 percent of discharges from 2000–2013 fell into this category, so this percent of the total number of Veterans in the ACS is subtracted from the priority group 8g group. The second class of Veterans is those who do not satisfy the required two-year length of service requirement. The size of this population was estimated using the corresponding question in the 2000 Decennial Census, which asks respondents whether they served less than two years. Because this population may contain individuals injured due to service and thus eligible for VA services

regardless of their less-than-two years of service, separate ratios were calculated for the disabled Veteran population and the non-disabled Veteran population, then these ratios were applied to the ACS Veteran population respectively, and the corresponding number of Veterans was subtracted from the priority group 8g pool. It should be noted that because these groups are treated independently, the resulting estimates of the size of these two ineligible groups is mechanically larger than the actual population, leading to the estimated 8g group being an underestimate or lower bound of this group of Veterans. This underestimate is even larger since the method accounting for those who do not satisfy their length-of-service requirement also includes some Veterans who will have received waivers for not satisfying this requirement and thus will be eligible for priority group assignment.

D.1.2   Changes in Presumptive Eligibility

D.1.2.1   Detailed Methodology for Estimating the Impact in Changes in Presumptive Eligibility

We estimated the maximum number of new VA patients that would utilize VA health care if VA decides that hypertension can be presumptively included as a service-connected condition for Veterans who served in the Vietnam Theater. Table D-1 presents our approach.

Table D-1. Estimate for New VA Patients If Hypertension Becomes A Presumptively Service-Connected Condition for Vietnam Veterans (thousands)

	Age of Veteran			Data Source
	58–64	**65–74**	**75–96**	
A. Vietnam Era (VNE) Veterans	1,475	5,015	661	NSV
1. Enrollees (1-6)	742	1,794	342	VA Business Intelligence Data
2. Enrollees (7-8)	195	558	286	VA Business Intelligence Data
3. Vietnam Era Veterans Not Enrolled	538	2,663	32	
4. Non-enrollees with "other than dishonorable" discharges	508	2,513	30	RAND Analysis of ACS Data
B. Vietnam Theater Veterans	319	2,441	322	NSV
C. Proportion of VNE Veterans in Theater (B/A)	0.22	0.49	0.49	
D. Hypertension prevalence (non-user Vietnam Era Veterans)	0.52	0.64	0.61	RAND Analysis of MEPS Data
E. Potential New Enrollees (A4*C*D)	57	779	9	
F. Hypertension Prevalence in current VHA users	0.67	0.71	0.71	RAND Analysis of MEPS Data
G. Estimated Number In Theater (A2*C)	42	272	140	
H. Potential Enrollees (7-8) moving up to a higher priority group (F*G)	28	192	98	

	Age of Veteran			Data Source
	58–64	**65–74**	**75–96**	
I. Estimated use	0.30	0.32	0.24	RAND Analysis of MEPS Data
J. Ceiling estimate for new *users* in priority groups 1-6 who served in theater and have hypertension ((E+H)*I)	25	312	26	
Total	363			

SOURCE: RAND analysis of NSV, MEPS, ACS, and VA Business Intelligence (Enrollment) data.

Since VA data systems do not track whether a Veteran served in the Vietnam Theater, we relied on estimates from NSV for the number of Veterans who served during the Vietnam Era as well as in the Vietnam Theater (rows A and B). We use VA Business Intelligence data on Veterans to estimate the number of VA enrollees by priority group (rows A1 and A2). Given data limitations, we make the simplifying assumption that enrolled Veterans between the ages of 58 and 96 (in 2014) primarily served during the Vietnam Era. Since it is likely that there are enrolled Veterans between those ages who did not serve during the Vietnam Era, this assumption will likely over estimate of the number of Vietnam Era Veterans who are already enrolled (and under estimate the number who are not enrolled in row A3). The error introduced by this assumption is offset by the fact that it is unlikely that all newly eligible Veterans will enroll and become patients, though we use ratios that assume that they will. In row A4, we adjust for the discharge status of Veterans. Based on our analysis of ACS data, we estimate that 94.4 percent of Veterans are discharged with "other than dishonorable" discharges. This is a population-wide estimate for all Veterans. Due to data limitations, we were not able to produce age-specific estimates.

To estimate the prevalence of hypertension, we use the Medical Expenditure Panel Survey (MEPS) Veteran patients and non-patients of VA and who, again by age, are were likely to have served in the Vietnam Era (rows D and F). We then apply the ratio hypertension prevalence and the proportion of Veterans who served in theater to the number of non-enrolled Veterans to produce a high-end estimate of potential new enrollees (row E).

When VA presumes that a health condition is service connected, a Veteran is typically eligible for a priority group of 6 or higher (up to 1). As such, presumptive eligibility determinations also have the effect of "promoting" enrolled Veterans in lower priority groups (7 and 8) to a higher priority group. To produce our estimate of the maximum number of priority group promotions (row H), we apply the hypertension prevalence and proportion of Veterans who served in theater to the number of Veterans enrolled in priority groups 7 and 8.

Up to this point, we have estimated the number of enrolled Veterans. To estimate the number who are likely to become new patients, we apply usage rates (by age) which we estimate using MEPS (row I).

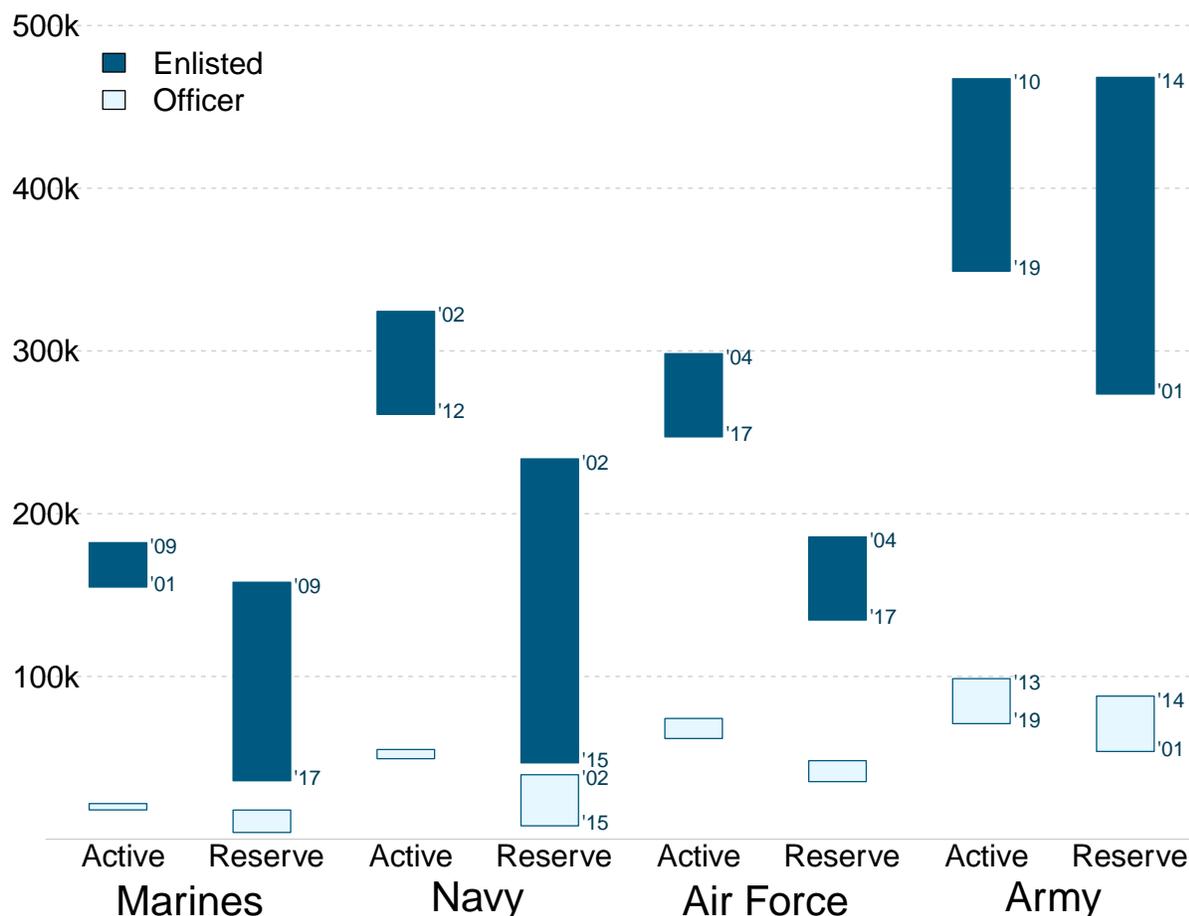
Using the above procedure, we estimate that the maximum number of new VA patients in priority groups 1–6 for this presumptive eligibility scenario to be 363,000 new VA patients.

D.1.3   Potential Impact of Future Conflict on VA Use

D.1.3.1   Maximum and Minimum End-Strengths in the Post-911 Period

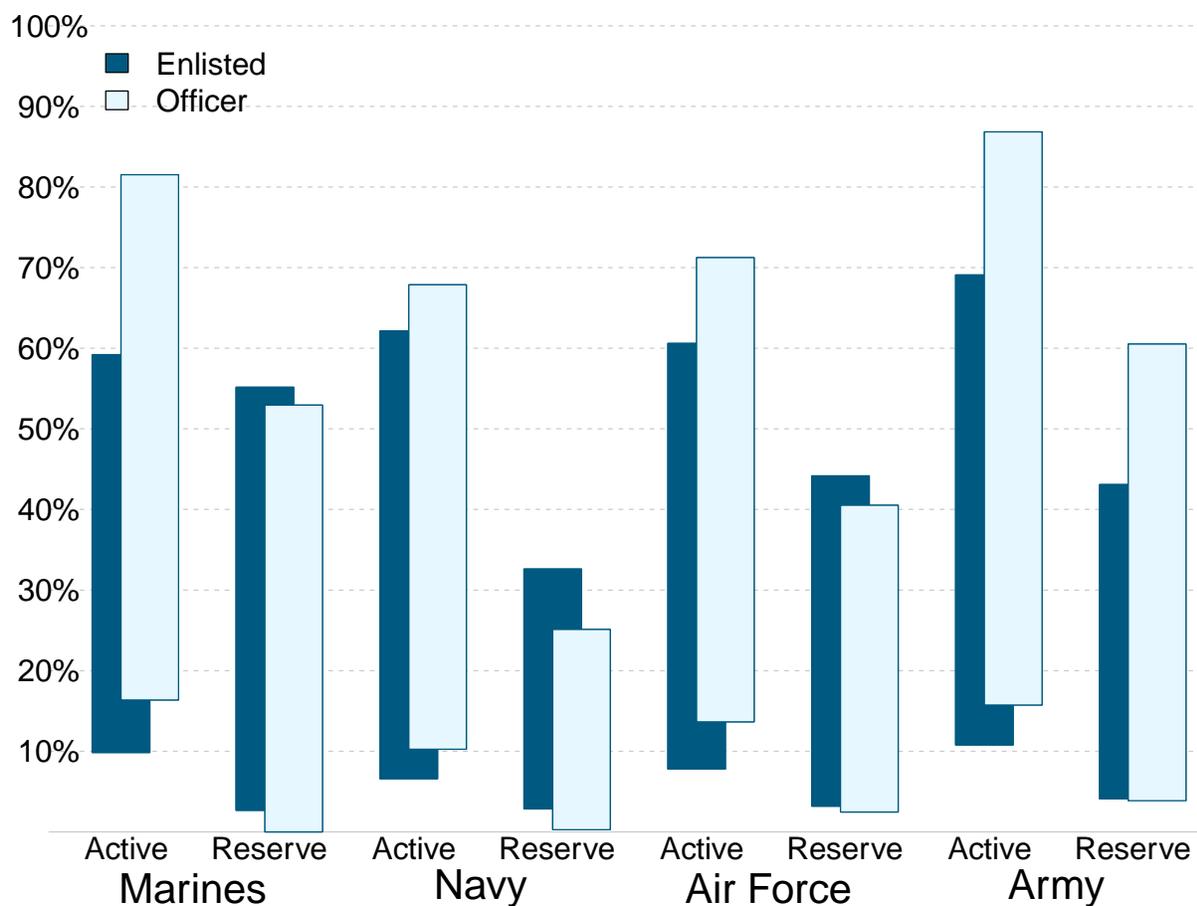
Figure D-1 reports the maximum and minimum number of non-civilian U.S. military personnel for each component of each service during the post-9/11 era. The top of each bar indicates the maximum, while the bottom of each bar denotes the minimum. The year to the right of each bar indicates the year in which that extreme occurred. Years before 2014 indicate that extreme value is derived from historical data, and years after 2014 derive from planning documents. For example, the Army reached its largest number (just under 500,000) of enlisted Reservists/National Guard in 2014. For example, the active component of the Army will reach its smallest size in 2019 (around 350,000). Year labels omitted for segments that have not varied by more than 10,000 over the entire post-9/11 period.

Figure D-1 reveals wide variation in end-strengths, both over time and by service. Comparing components, reserve and National Guard components have experienced (or are expected to experience) far more variation in end-strength, compared to active components. However, the air force is a notable exception. Comparing services, the Army has both the largest size and the most variation in size. In all cases, officers comprise a very small portion of total end-strength.

Figure D-1. Maximum and Minimum Non-Civilian U.S. Military Personnel


D.1.3.2   Possible Range of Conflict Exposure, By Segment of the Military Personnel

Figure D-2 reports the maximum and minimum percentage of separations in a given year that had been deployed into a combat environment. Following mostly peaceful late 1990s, less than 20 percent of separating service members had been deployed into a combat zone, as shown by the bottoms of the bars. During the latter years of the Afghanistan and Iraq missions, over 60 percent of active component separators had experienced at least one deployment. Several aspects of D-2 are notable. First, officers in the active components all tended to experience higher rates of conflict exposure than the enlisted members of their service. Second, Marines and soldiers experienced significantly higher maximum rates of conflict exposure than airmen and sailors. Third, even among those separating before the start of the Iraq and Afghanistan missions and after serving during the mostly peaceful late 1990s, conflict exposure rates for active component separating service members hovered around 10 percent, not 0 percent.

Figure D-2. Maximum and Minimum Rates of Hostile Deployment


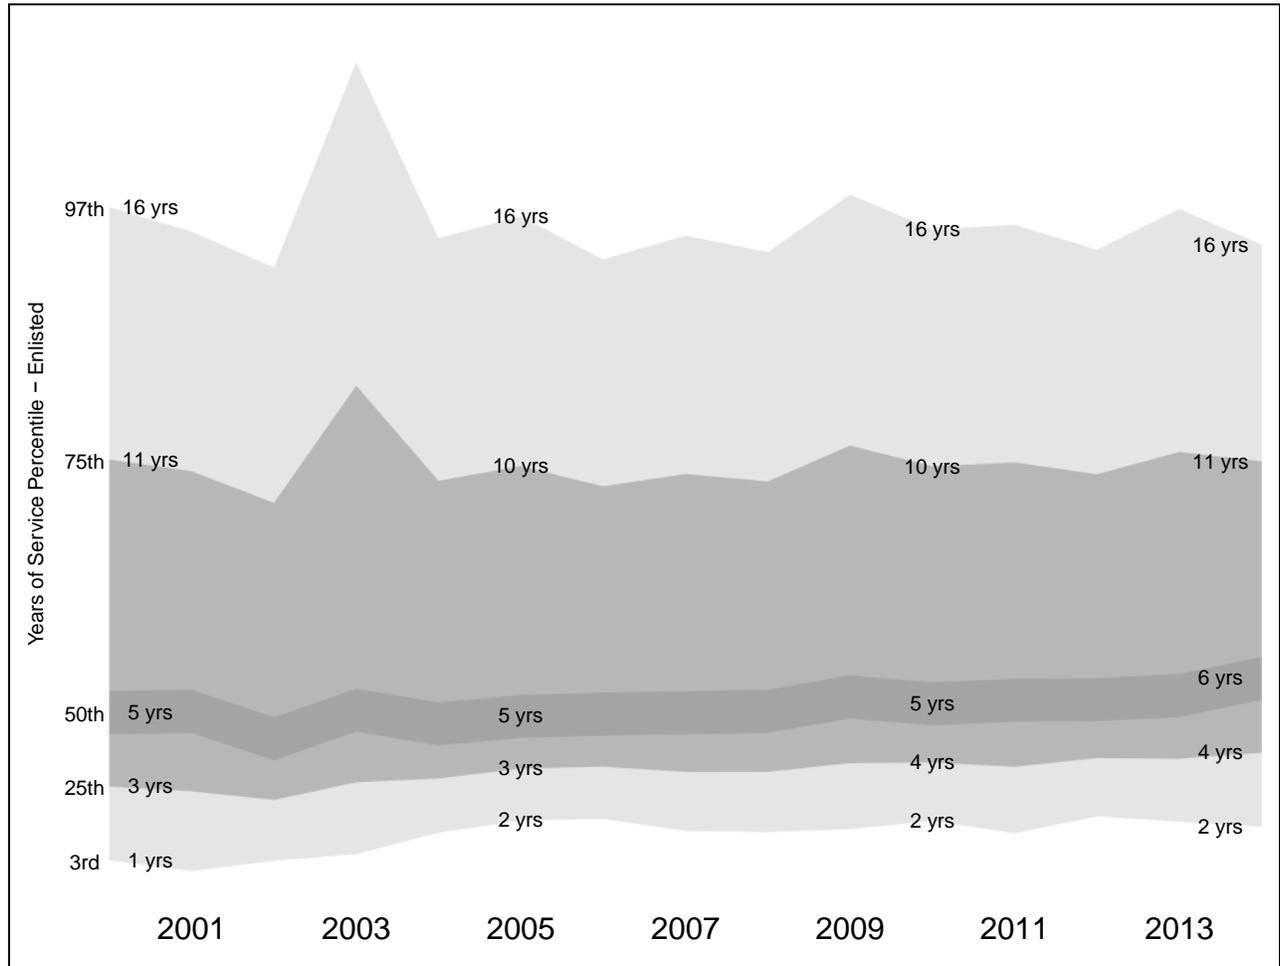
SOURCE: DoD Administrative data (2014)

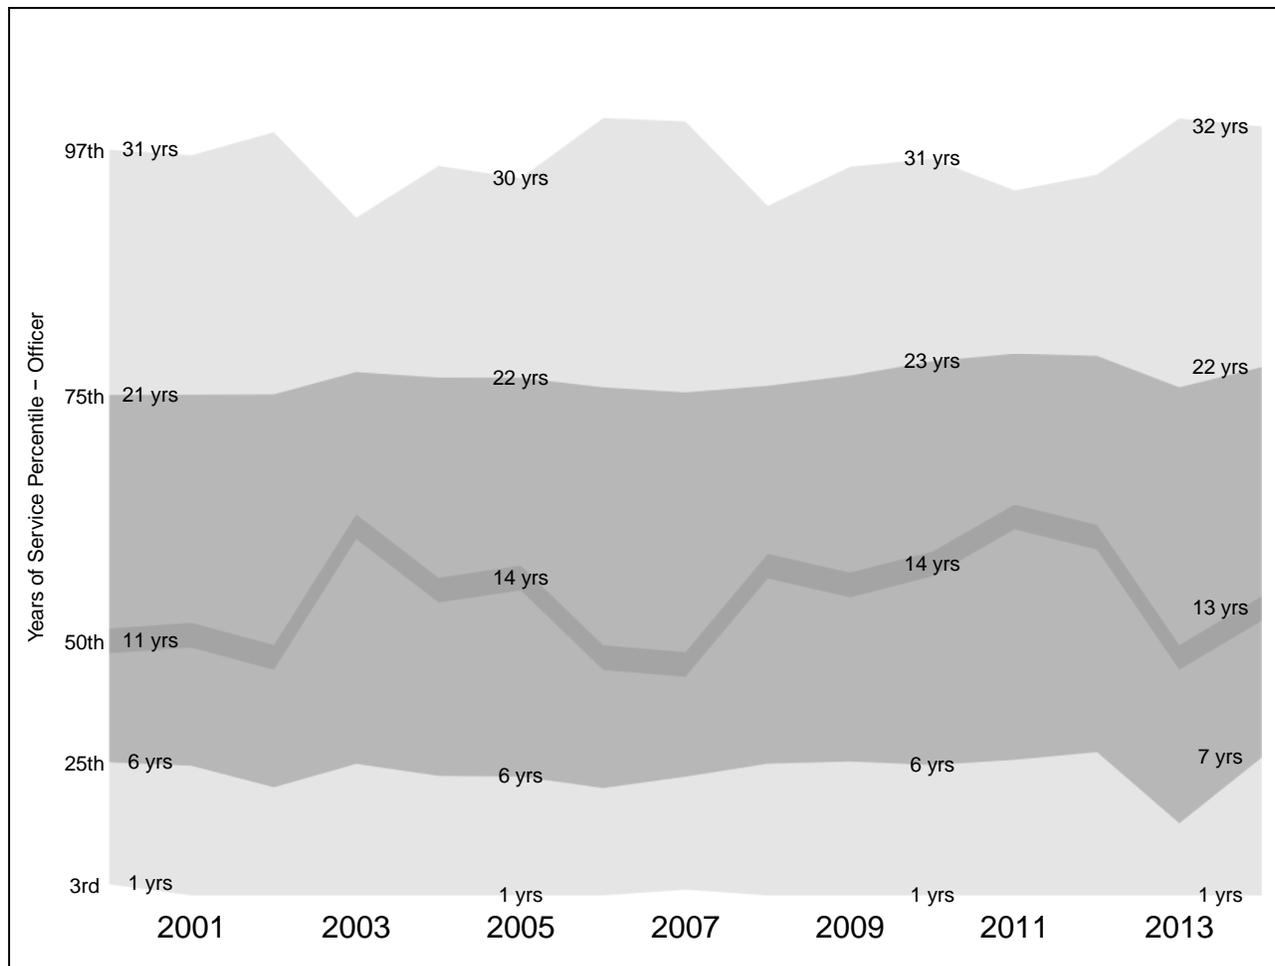
D.1.3.3   Typical Length of Service

Figure D-3 reports the percentile distribution of active officers/enlisted separating with a given number of years of service for each year between 2000 and 2014. The top panel reports years of service for enlisted members of the active component military. The bottom panel reports years of service for officers. In each figure, the shading indicates the percentile distribution of years of service among separating service members in that year. For example, in 2005, the bottom 3 percent of officers separated with a year or less of active duty service. 25 percent of officers separated with six years or less, 50 percent with 14 years or less, and so forth. In contrast, 50 percent of separating officers in 2000 had served 11 years—notably less. In essence, the darkest shading (50th percentile) plots the average years of service of separating service members, the next darkest shade (25th-75th percentile) reports the typical variation of years, and the lightest shade (3rd-97th percentile) provides some sense of the wider range of service years.

The top panel reports those figures for enlisted separations. The typical enlisted service member separates with three to 11 years of active service, with five or six years being most common. In general, the distribution of years of service is very skewed, with very few service members separating two years sooner than the average length of service, but many more than two years longer than the average. Despite stop loss, the surge, and the wars, the average years of service remained mostly steady throughout the 2000–2014 period.

The bottom panel reports years of service for officers. The average officer serves two to three times as long as average enlisted service member, with over a quarter spending more than 20 years in service. Iraq and Afghanistan may have affected the years of service among officers far more than enlisted. With the exception of 2006–2007, officers separating after 2003 averaged at least three more years in service, compared to those separating between 2000 and 2002.

Figure D-3. Typical Years of Service for Active Component Service Members, Officers vs. Enlisted




SOURCE: DoD Administrative data (2014)

D.1.4   The ACA's Coverage Expansion

Our approach to estimate the potential impact of the ACA coverage expansion combines two separate calculations: first, an estimate of the number of uninsured Veterans that could enroll in VA health care to obtain qualifying coverage under ACA and later use VA health care services; and second, an estimate of the number of current VA patients who will take advantage of new coverage opportunities and stop using VA services. Both calculations involve three related steps:

1. Estimate the starting population using the NSV

2. Apply an estimate of how health insurance coverage will change over time from the RAND COMPARE microsimulation model, a tool designed to help policymakers understand the coverage impacts of health reform

3. Apply enrollment and use rates to translate coverage changes into impacts measured in terms of the number of Veterans enrolled in VA health care and the number of VA patients.[66]

The fourth and final step is to sum the two separate impacts to arrive at an overall net impact.

This approach is intended to illustrate the potential impacts of the ACA coverage expansion. Evidence on the impacts of the ACA coverage expansion in general is developing but incomplete, and evidence on the impacts on Veterans specifically is sparse. In addition, key coverage expansion provisions may change in the future as a result of implementation decisions, such as states opting to expand their Medicaid programs. As a result of these uncertainties, in addition to reporting estimates from a set of base case assumptions we also discuss impacts under a wide range of other assumptions.

The following sections walk through our detailed methodology for each of the three steps, separately for the uninsured-to-enrollee and the patient-to-non-patient calculations.

D.1.4.1 Estimating the Uninsured to VA Enrollee Impact

As a first step, we used the NSV to calculate the number uninsured Veterans that were not VA patients. We used a "No" response to NSV item E2, "Have you ever used any VA health care benefits?" to identify Veterans that were not VA patients. We applied a hierarchical approach to categorize each respondent into a single coverage category. The hierarchical approach was necessary because Veterans often report multiple forms of coverage, for example, VA health care and Medicare. We used coverage information reported in NSV item E1. The specific criteria were as follows:

- Private coverage only: ("Insurance through a current or former employer or union (of yours or another family member)" OR "Insurance purchased directly from an insurance company (by you or another family member)") AND no other source of coverage reported.

- Medicare only: "Medicare, for people 65 and older, or people with certain disabilities" AND no other source of coverage reported.

- Medicaid only: "Medicaid, Medical Assistance, or any kind of government-assistance plan for those with low incomes or a disability" AND no other source of coverage reported.

- TRICARE only: "TRICARE or other military health care" AND no other source of coverage reported.

- Other only: ("Indian Health Service" OR "Any other type of health insurance or health coverage plan") AND no other source of coverage reported.

- Private and Medicare: ("Insurance through a current or former employer or union (of yours or another family member)" OR "Insurance purchased directly from an insurance

---

[66] Our analysis takes into account both the geographic distribution of Veterans and states' decisions to expand Medicaid. Veterans who live in non-expansion states are therefore less likely to gain a new source of insurance under the ACA than Veterans who live in expansion states.

company (by you or another family member)") AND "Medicare, for people 65 and older, or people with certain disabilities" AND no other source of coverage reported.

- Medicare and TRICARE: "Medicare, for people 65 and older, or people with certain disabilities" AND "TRICARE or other military health care" AND no other source of coverage reported AND no other source of coverage reported.

- Any other combination: All other Veterans reporting health insurance coverage other than "CHAMPVA (Civilian Health and Medical Program of VA)"

- Uninsured or VA only: Veterans that did not satisfy any of the above criteria.

We also assigned each NSV respondent to a household income category using NSV item K2, "Which income range category represents your total combined income during the past 12 months?" For tractability and in order to ensure that we could link with other data we used the single adult FPL thresholds and did not adjust for family size. The estimated number of uninsured, non-VA patient Veterans were 698,000 under 133 percent FPL, 227,000 between 133 and 400 percent FPL, and 81,000 above 400 percent FPL.

The next step involved applying estimates on the proportion of uninsured individuals that would gain coverage through some other source—for example, Medicaid or the health insurance exchanges. We used the RAND COMPARE ratios for the proportion of the uninsured population that would gain coverage by 2016 for the three income bands: 34 percent for <133 percent FPL, 69 percent for 133 to 400 percent FPL, and 63 percent above 400 percent FPL. We multiplied the starting population by these factors to determine how many Veterans would gain coverage and how many would not gain other coverage, assuming that Veterans had and took advantage of opportunities for other coverage at the same rates as the U.S. population by income band as estimated by COMPARE (see Table D-2).

Table D-2. Estimated Number of Uninsured Veterans that Were Not VA Patients and Predicted to Gain or Not Gain Other Coverage by 2016

Poverty Level	Uninsured, Non-VA Patient Veterans	RAND COMPARE estimate, uninsured gaining coverage	Gaining other coverage	Not gaining other coverage
<133% FPL	698,000	34.4%	240,000	458,000
133-400% FPL	227,000	68.8%	156,000	71,000
>400% FPL	81,000	62.7%	51,000	30,000
Total	1,007,000		447,000	559,000

We used our analysis in the ACS data (described earlier in Section 6) to estimate the share of Veterans that were not VA patients in different coverage and income categories that would be eligible to receive VA health care services. Some Veterans are not eligible to receive care due to a dishonorable discharge or insufficient length of service. Other Veterans would fall in priority groups 8e or 8g which are not currently eligible to receive VA health care services. We estimated that virtually all Veterans under 133 percent FPL were potentially eligible. However only 58 and 13 percent of Veterans in the 133 to 400 percent FPL and 400 percent FPL categories, respectively, were predicted to be eligible to receive care. We deflated the counts

of Veterans in Table D-2 using these factors to estimate the number of uninsured Veterans that were not VA patients but that were predicted to be eligible to enroll to receive VA health care services (Table D-3).

Table D-3. Estimated Number of Uninsured Veterans that Were Not VA Patients, Predicted to be Eligible to Enroll in VA Health Care, and Predicted to Gain or Not Gain Other Coverage by 2016

Poverty Level	Gaining other coverage	Not gaining other coverage	Percent Likely Eligible To Receive Care	Gaining other coverage and Likely Eligible	Not gaining other coverage and Likely Eligible
<133% FPL	240,000	458,000	100%	240,000	458,000
133-400% FPL	156,000	71,000	57.6%	90,000	41,000
>400% FPL	51,000	30,000	13.1%	7,000	4,000
Total	447,000	559,000	89.9%	337,000	503,000

We made different enrollment rate assumptions for different groups of Veterans. We applied a single enrollment rate (X percent) to uninsured, likely eligible Veterans that we predict would not gain other coverage regardless of income level. We used a more nuanced approach for uninsured, likely eligible Veterans that we predict would gain other coverage to account for the impacts of choices and Marketplace subsidies especially at lower income levels. For these Veterans, we applied a base enrollment rate (Y percent) to the >400 percent FPL population. We applied half of this base enrollment rate to the 133–400 percent FPL population to account for the fact that Marketplace subsidies might make private coverage more appealing to Veterans. Finally, we applied a quarter of the base enrollment rate to the <133 percent FPL population because these Veterans can choose between Medicaid (in some states), Marketplace, and VA for low-cost coverage.

Table D-4 reports the number of enrollees at each 10-percent increment of the two key enrollment rates—X percent and Y percent. We propose X=50 percent and Y=50 percent as a base case. The estimated number of new enrollees ranges from 0 in the upper left corner of Table D-4 to 614,000 in the lower right corner of Table D-4. The base case estimate is 307,000.

Table D-4. Thousands of Estimated New VA Enrollees At Different Enrollment Rate Assumptions

Enrollment Rate, No Other Coverage (X%)	Base Enrollment Rate, Other Coverage Options (Y%, which varies by income*)										
	0%	10% 5% 2.5%	20% 10% 5%	30% 15% 7.5%	40% 20% 10%	50% 25% 12.5%	60% 30% 15%	70% 35% 17.5%	80% 40% 20%	90% 45% 22.5%	100% 50% 25%

* For Veterans who gain other coverage options as a result of the ACA, we assume their enrollment rate varies depending on the degree of subsidy that they receive for these options. Veterans who gain access to unsubsidized employer coverage have a VA enrollment rate of Y%, Veterans who gain access to Marketplace subsidies have an enrollment rate of Y/2%, and Veterans who gain access to Medicaid coverage have an enrollment rate of Y/4%.

As a last step for this first of two calculations, we applied a use rate on top of the estimated number of newly enrolled Veterans to arrive at an estimate of new VA patients. The actual use rate for newly enrolled, previously uninsured Veterans is difficult to predict. Some newly insured Veterans might avail themselves of new coverage, although these Veterans had been eligible for coverage prior to ACA and opted not to enroll. Other Veterans might enroll to gain qualifying coverage but might not regularly interact with the VA health care system. Use rates for these Veterans may increase over time as they have more interaction and exposure to VA health care. In order to generate use rates for our analysis, we calculated the use rate across Veterans who have private coverage only using NSV data. The use rate was 14 percent for Veterans with incomes >400 percent FPL, 20 percent for Veterans with incomes between 134 and 400 percent FPL, and 25 percent for Veterans with incomes <134 percent FPL. Table D-5 reports estimates of new patients calculated by applying these use rates to the previous estimates of new enrollees. Under the base case assumptions, we estimate 74,000 new VA patients.

Table D-5. Thousands of Estimated New VA Patients At Different Enrollment Rate Assumptions

40%	49	51	54	56	59	61	64	66	69	71	74
50%	61	64	66	69	71	74	76	79	81	84	86
60%	73	76	78	81	83	86	88	91	93	96	98
70%	86	88	91	93	96	98	101	103	105	108	110
80%	98	100	103	105	108	110	113	115	118	120	123
90%	110	113	115	118	120	122	125	127	130	132	135
100%	122	125	127	130	132	135	137	140	142	145	147

*We hold the use rate constant across all scenarios but allow the enrollment rate to vary. For Veterans who gain other coverage options as a result of the ACA, we assume their enrollment rate varies depending on the degree of subsidy that they receive for these options. Veterans who gain access to unsubsidized employer coverage have a VA enrollment rate of Y%, Veterans who gain access to Marketplace subsidies have an enrollment rate of Y/2%, and Veterans who gain access to Medicaid coverage have an enrollment rate of Y/4%. The use rate is 14 percent for Veterans with incomes above 400 percent of FPL, 20 percent for Veterans with incomes between 134 and 400 percent of FPL, and 25 percent for Veterans with incomes below 134 percent of FPL.

D.1.4.2 Estimating the Impact of Veterans Gaining Other Coverage

For the second calculation, we started in the same way as the first calculation by estimating the size of the relevant population using NSV. We used the same approach to defining coverage to estimate the number of Veterans in each income group that was enrolled in VA health care and did not have any other source of health care coverage. We also applied the same factors from RAND COMPARE to estimate the proportion of Veterans in each category that could gain another form of coverage by 2016. Table D-6 reports the number of Veterans in each income category overall and by whether or not they could gain another form of coverage.

Table D-6. Estimated Number of Veterans with Only VA Coverage and Predicted to Gain or Not Gain Other Coverage by 2016

Poverty Level	Uninsured, Non-VA Patient Veterans	RAND COMPARE estimate, uninsured gaining coverage	Gaining other coverage	Not gaining other coverage
<133% FPL	761,000	34.4%	262,000	500,000
133-400% FPL	479,000	68.8%	329,000	149,000
>400% FPL	208,000	62.7%	130,000	77,000
Total	1,447,000		721,000	726,000

We calculated a reduction in the number of VA patients assuming that the 727,000 Veterans would shift to a lower use rate than their current rates. Use rates for Veterans with no other source of health coverage are very high—85 percent for Veterans over 400 percent FPL and approximately 97 percent for Veterans at lower incomes. Use rates calculated across all Veterans with Medicaid or Private insurance are significantly lower (between 14 and 25 percent). In addition, Veterans eligible for exchange subsidies may have to dis-enroll in VA health care to qualify for subsidies. We decreased use rates by 25 percent to reflect lower utilization of VA health care services by Veterans with multiple coverage options.

If all Veterans that we predict will gain coverage do so and shift to the lower use rate immediately, we would expect 172,000 fewer VA patients in the following year. Different combinations of these Veterans' current and potential future use rates result in estimates ranging from 0 fewer patients (assuming that these Veterans continue to use VA health care at the same rates that they do today despite gaining coverage) to 721,000 fewer patients if all Veterans predicted to gain other coverage immediately begin accessing care through their other coverage rather than VA.

D.1.4.3 Net Impact

Under the base case, the net impact is the sum of 74,000 new, previously uninsured VA patients and 172,000 fewer VA patients due to Veterans gaining other coverage, or a net decrease of about 98,000 VA patients. Different combinations of assumptions at different points in the analysis yield significantly different net impacts—and in some cases net increases in the number of VA patients, for example, if Veterans gaining new coverage continue to use VA health care services at high rates and significant shares of uninsured Veterans enroll to gain qualifying coverage and then use health care services.

Preface

Congress enacted and President Obama signed into law the Veterans Access, Choice, and Accountability Act of 2014 (Public Law 113-146) ("Veterans Choice Act"), as amended by the Department of Veterans Affairs (VA) Expiring Authorities Act of 2014 (Public Law 113-175), to improve access to timely, high-quality health care for Veterans. Under "Title II – Health Care Administrative Matters," Section 201 calls for an Independent Assessment of 12 areas of VA's health care delivery systems and management processes.

VA engaged the Institute of Medicine of the National Academies to prepare an assessment of access standards and engaged the Centers for Medicare & Medicaid Services (CMS) Alliance to Modernize Healthcare (CAMH)[1] to serve as the program integrator and as primary developer of the remaining 11 Veterans Choice Act independent assessments. CAMH subcontracted with Grant Thornton, McKinsey & Company, and the RAND Corporation to conduct 10 independent assessments as specified in Section 201, with MITRE conducting the 11th assessment. Drawing on the results of the 12 assessments, CAMH also produced the Integrated Report in this volume, which contains key findings and recommendations. CAMH is furnishing the complete set of reports to the Secretary of Veterans Affairs, the Committee on Veterans' Affairs of the Senate, the Committee on Veterans' Affairs of the House of Representatives, and the Commission on Care.

The research addressed in this report was conducted by the RAND Corporation, under a subcontract with The MITRE Corporation.

Executive Summary

Access to quality health care is a central part of our nation's commitment to Veterans. In February 2014, a recently retired Department of Veterans Affairs (VA) physician alleged that at least 40 Veterans died while waiting for care at the Phoenix VA Health Care System. While the allegations of deaths were not proven, this raised concerns about how effectively the commitment to Veterans was being fulfilled (VA, Office of Inspector General, 2014). Following the Phoenix allegations, the VA Office of Inspector General investigated the timeliness of VA health care, finding that some VA staff regularly entered false information regarding patients' preferred dates of care to minimize reported wait times between the preferred date and the actual date of appointments. The Inspector General also pointed to systemic issues within VA that may limit Veterans' access to care, including lack of available appointments within certain clinical specialties and problems with care transitions for patients discharged from mental health services.

The accessibility and timeliness of care are longstanding areas of concern within VA. VA has many ongoing programs and initiatives to increase access to care for Veterans, including, most recently, the Veterans Choice Act, passed in 2014. The Veterans Choice Program expanded VA authority to furnish care to Veterans through agreements with non-VA providers as well as provisions regarding improved access to telemedicine through mobile medical centers; 27 new major medical facility leases; increased transparency of performance data on VA providers, including wait times; new residency and other training and education programs; and recruitment and appointment of personnel in occupations identified by the VA Inspector General as having the greatest shortages. The law includes appropriations for VA to support these activities.

Section 201 of the Veterans Choice Act included a requirement for 12 independent assessments of VA health care. This report addresses Assessment B (identified under Title II – Health Care Administrative Matters, Section 201 of the Veterans Choice Act). The assessment responds to language in the Veterans Choice Act of 2014, Title II – Health Care Administrative Matters, Section 201.A.1.b, which mandates an independent assessment of "current and projected health care capabilities and resources of the Department [VA], including hospital care, medical services, and other health care furnished by non-Department facilities under contract with the Department, to provide timely and accessible care to veterans" (Veterans Choice Act, Section 201).

Study Purpose and Approach

Assessment B assesses VA's current and projected resources and capabilities, the level and nature of access to VA care, and barriers and facilitators to access. We explore how selected policies could affect Veterans' access to high-quality care. Specifically, we address the following research questions:

1. What are VA's current resources and capabilities in key domains?

2. What are current levels of access to VA care?

3. What is the quality of care in VA?

4. What are VA's projected resources and capabilities to provide timely and accessible care, and how might different policy options enhance VA's resources and capabilities for treating Veterans in the future?

We answered these questions broadly and also identified seven illustrative clinical populations to provide a more detailed understanding of VA capabilities, resources, and accessibility in selected subpopulations of Veterans.

The Assessment B team used a multipronged approach to address these research questions. We examined VA's resources and capabilities in five domains (fiscal, workforce and human resources, physical infrastructure, interorganizational relationships, and information technology [IT]). To understand access, we examined available data on five dimensions of access to VA health care: geographic, timely, financial, digital, and cultural. We assessed the quality of VA health care in comparison with non-VA care as measured in previous studies and by analyzing more recent VA performance data, using the six dimensions of health care quality identified by the Institute of Medicine: Care should be safe, timely, equitable, effective, efficient, and patient-centered (Institute of Medicine, 2001).

We also developed a method for projecting future resources, which we compared with forecasted changes in patient demand for VA health care in order to identify potential gaps. To support analyses of future options for VA to address identified gaps, we identified and analyzed a reasonable range of feasible policy options to enhance VA's ability to provide timely and accessible care to Veterans. These analyses were informed by data collected through literature reviews, key informant interviews, a 2015 Survey of VA Resources and Capabilities, and other VA and non-VA data sources.

Findings

Assessment of VA Resources and Capabilities

VA operates a unique health care system with broad and deep resources and capabilities for Veterans, including facilities, personnel, and IT infrastructure. However, our assessment identified a number of barriers to the effective planning for and use of these resources and capabilities, which can affect their availability to Veterans.

VA faces a number of challenges in planning for and using its fiscal resources effectively. The total VA budget for fiscal year (FY) 2015 is approximately $60 billion, rising to $63 billion for the advanced FY 2016 appropriation. We were not able to determine whether VA has adequate fiscal resources for health care, because there is no valid benchmark against which to compare VA's budget and spending. We did find, however, a number of issues related to VA's budget process, including concerns about the data used for budget planning, inflexibility in budgeting stemming from the congressional appropriation processes, and challenges in VA's allocation processes. VA develops its health care budget from older data, and there can be problems with the assumptions used in this process. In addition, congressional priorities can affect VA's appropriation, and the impact of increases in purchased care from the Veterans Choice Act on

---

the budget in future years is currently unknown. In interviews, facility directors described problems with the allocation system to the Veterans integrated service networks (VISNs), including the use of past data in calculating the allocation and the fact that some facilities undertake various activities to ensure that their allocation is as high as possible in subsequent years. These challenges can leave facilities that are experiencing change over- or underfunded in the current year, and they create incentives for facilities to see more of certain types of patients in order to increase funding in future years. There are also continued challenges with the separate budgets for medical care, capital construction, and IT that do not move in concert and can limit facilities' ability to improve access.

VA has an extensive health care workforce but faces challenges in workforce planning and assessment. As one of the largest providers of health services in the world, VA employs physicians, nurses, other providers, and a range of support staff to provide care directly to Veterans. VA also contracts with private physicians to deliver some services within VA facilities (GAO, 2013b). In FY 2014, VA employed a total of 31,269 physician employees working either full-time or part-time, for a total of 19,900 FTEs. On average, these physicians spend close to 80 percent of their FTEs in clinical care, for a total of 15,543 physician clinical FTEs across all specialties. We identified several challenges associated with VA workforce planning and assessment processes. These include a lack of guidance about what methods should be used, a lack of external productivity benchmarks, inaccurate or incomplete data inputs, and the inability of the data system to adequately account for certain types of providers and patient visits.

VA workforce capacity may not be sufficient to provide timely care to Veterans across a number of key specialties as well as primary care. VA faces shortages of physicians in some geographic areas and of certain physician specialists more generally. These constraints are influenced by a number of key factors, including relatively low salaries, a slow credentialing process, and infrastructure constraints. We found significant variation across facilities and VISNs in terms of productivity. Our estimates must be considered, however, in light of concerns about coding and data quality. In particular, interviewees reported that variations in coding practices, inconsistently entered workload data, and incomplete or poorly detailed physician encounter data make it difficult to consistently measure productivity.

VA operates one of the most extensive systems of health care infrastructure in the country, but the need for additional physical space is a limiting factor in improving access. Of 955 sites, 871 are medical facilities; the remaining sites, considered nonmedical facilities, generally provide outpatient services or residential treatment. On average, the VA system has 18.3 hospital beds per 10,000 enrollees and an inpatient daily census of 11 patients per 10,000 enrollees, for an occupancy rate of 60 percent; however, hospital bed supply varies widely across VISNs. Interviewees in leadership or clinical care positions were generally satisfied with VA medical equipment and supplies, but they noted that physical space was in short supply and that even new facilities can quickly grow out of date. The need for more effective use of existing space was also identified as a key limiting factor in improving access for Veterans.

VA has many outside options for providing care to Veterans, although managing this resource can be challenging. Care is provided to VA enrollees by non-VA entities through several

---

programs and various types of payment or contractual arrangements, including the "traditional program," partnership agreements, the Access Received Closer to Home (ARCH) program, the Patient Centered Community Care (PC3) program, and the Veterans Choice Program. Spending for purchased care has grown dramatically—reaching about $7 billion in 2014—and the Veterans Choice Act provides new funding of $10 billion over three years. However, managing this complex resource has proven challenging. Contracting with non-VA providers has been described as a "long and painful" process, and there are well-documented problems with VA's claims processing system. As VA was attempting to address some of the administrative challenges associated with arranging, coordinating, and reimbursing purchased care through the implementation of the PC3 program, for example, the addition of the Veterans Choice program further complicated the situation and resulted in confusion among Veterans, VA employees, and non-VA providers. VA and members of Congress have expressed a desire to more effectively utilize this important resource as demand increases.

VA has been and continues to be an innovator and leader in developing health IT capabilities, although there is room for improvement in some areas. VA is on par with or exceeds other organizations' capability to use IT in care delivery in many regards, including telehealth and MyHealtheVet, VA's online patient portal. However, VA's role as an innovator and leader has been challenged by issues related to the management and planning of its IT systems. For every IT capability we studied, we found clear barriers—including inadequate infrastructure, lack of facility leadership and provider buy-in, and administrative burden—to allowing Veterans to take further advantage of what IT can offer.

Our findings also confirm the results of previous studies concerning strengths and weaknesses in VA's current electronic health record technologies (VistA, that is, Veterans Health Information Systems and Technology Architecture, and VA's Computerized Patient Record System [CPRS]), which suffer from an aging architecture and 10 years of limited development. However, interviews across the spectrum of VA personnel—from management and IT thought leaders to end users—suggest strong support for renewed investment in a modern, home-grown product rather than transitioning to a commercial off-the-shelf alternative. The advantages, disadvantages, and tradeoffs between homegrown versus commercial electronic health record software are discussed in Assessment H.

Taken together, these barriers present a formidable, though not insurmountable, challenge to ensuring that sufficient VA resources and capabilities are available to all Veterans. Addressing these barriers will require a mix of short- and long-term initiatives, as we describe later in the Recommendations section.

Assessment of Access to VA Care

Ensuring Veterans' access to health care depends not just on the level of resources and capabilities available, but on how well VA's health care system addresses Veterans' needs. While our assessment did not find evidence of a system-wide crisis in access to VA care, we found considerable variability across the different dimensions of access (geographic, timely, financial, digital, and cultural) as well as opportunities to improve access, even at the top-performing VA facilities.

Veterans' geographic access to VA care varies according to the access standard used and by region and type of service. Many Veterans have geographic access to VA care, although it varies when using different access standards (that is, 40-mile straight-line distance, 40-mile driving distance, 60-minute driving time in free-flow traffic or rush hour traffic, 60-minute public transit time) and by region. Enrollees' average driving time to the nearest VA medical center (VAMC) or hospital is less, on average, than enrollees' average reported willingness to travel for routine medical care or Medicare beneficiaries' observed average travel times. Veterans who must rely on public transportation have much less access than other Veterans. Further, our assessment found that substantially lower proportions of enrollees have geographic access to advanced and specialized services in VA medical facilities. For example, only 43 percent of enrollees live within 40 miles of VA interventional cardiology services, and only 55 percent of enrollees live within 40 miles of VA oncology services.

Veterans who live far from a VA medical facility have good geographic access to non-VA community hospitals, emergency care, and primary care physicians, but poor access to hospitals and physicians offering specialized services. Nearly all Veterans (96 percent) who live far from VA medical facilities can drive to community and emergency care at non-VA hospitals within 40 miles, but access to more advanced care at academic and teaching hospitals is much lower: Only 15 percent live within 40 miles of a teaching hospital, and only 3 percent live within 40 miles of an academic hospital. These Veterans are also less likely to have geographic access to a range of highly specialized care at non-VA hospitals, including many cardiology, surgery, and oncology services. The same is true for access to non-VA clinicians in the community. A large share of VA enrollees living far from a VA medical facility are within 40 miles of primary care providers, but far fewer of these enrollees are near providers offering highly specialized care. This finding suggests that expanding access to non-VA providers in these regions can help most Veterans seeking routine and emergency care, but will help far fewer Veterans who need access to advanced and specialized care.

Most VA appointments meet VA timeliness standards; however, there is variation in timeliness across the VA system, with poor performance for some VA facilities. Most Veterans complete their appointments within VA timeliness standards of 30 days of the preferred date—that is, the date recommended by the physician or that the Veteran prefers. However, some Veterans who do not receive care within 30 days may be at risk of poor health outcomes. The average number of days that Veterans wait for appointments varies tremendously across VA facilities, indicating substantial opportunities for improvement in some facilities. At 91 top-performing VA facilities, over 96 percent of new primary care patients receive appointments within 30 days of the preferred date. However, 14 VA facilities were far below this benchmark, with less than 84 percent of patients receiving appointments within 30 days of the preferred date. At the top-performing VA facilities, more than 60 percent of Veterans report that they "always got urgent care appointments as soon as needed." At the worst-performing VA facility, this rate was closer to 20 percent. Even at the facilities with the shortest wait times, many Veterans report that they do not always get an appointment as soon as needed, suggesting that even these top-performing facilities do not meet many Veterans' expectations for timely appointments.

Reported wait times for VA care are getting longer. The percentage of appointments completed within 30 days of the preferred date was lower in the first half of FY 2015 than in the first half of FY 2014. Reported declines over this period likely reflect both actual lengthening of wait times—as might be expected, given the increased demand for VA services predicted by VA's Enrollee Health Care Projection Model (EHCPM)—and improvements in the accuracy of the wait-time data.

VA's timeliness standard is much less demanding than alternative standards that have been proposed in the private sector. The standard is also sensitive to the definition of the "preferred date," which has been subject to gaming. For example, the VA Inspector General found that VA staff regularly entered false information regarding preferred dates of care. Therefore, many have questioned whether the VA data and standard provide a valid reference for timeliness of appointments. While it was outside the scope of this assessment to validate these data, we examined whether alternative standards for timeliness could be applied. Alternative standards, such as those that assess the availability rather than completion of appointments, may be less subject to gaming and more comparable to private-sector standards. It is unclear how many VA facilities or non-VA providers meet these alternative standards. We found limited data available to compare VA and non-VA waits for care, but VA wait times do not seem to be substantially worse than non-VA waits, based on the limited available evidence.

On patient surveys, Veterans are substantially less likely than private-sector patients to report getting appointments, care, and information as soon as needed. The top-performing VA facilities scored comparably or worse than average practices in the Consumer Assessment of Healthcare Providers and Systems (CAHPS) Database, which includes a voluntarily participating set of private-sector medical practices and likely overrepresents high-performing practices. VA facilities at the 75th percentile of VA performance scored substantially worse than average CAHPS Database practices.

VA care is considered to be relatively affordable, and demand for VA care may increase if the cost of health care increases. VA is often Veterans' most affordable option for health care coverage. Veterans typically face lower out-of-pocket costs for care in VA than they would if they were privately insured. VA health care workers noted that lack of an affordable private insurance option is a key reason why Veterans enroll in VA. Twenty-eight percent of Veterans responding to the 2014 Survey of Enrollees indicated that their use of VA care would decrease if their financial resources improved. This suggests that, for a substantial minority of Veterans, non-VA care is preferred if available. In interviews, VA administrators and representatives of Veteran Service Organizations noted that Veterans generally like to get their care from VA, but that some Veterans with affordable non-VA care options seek care elsewhere rather than dealing with challenges associated with determining eligibility for services, perceived longer wait times, inconvenience of scheduling processes, and less than state-of-the-art equipment and facilities within VA.

Many Veterans, especially older Veterans, lack Internet access, but the acceptability of digital care is likely to grow as younger Veterans age. Thirty percent of Veterans, especially older Veterans, do not have access to the Internet and therefore cannot access VA's digital services, such as the MyHealtheVet patient portal or telehealth (2013 Survey of Enrollees). As younger

---

Veterans age, Internet access and technological skill are likely to grow more common among Veterans, thereby increasing the acceptability and accessibility of digital health care services.

More could be done to increase VA providers' awareness of the changing demographics among Veterans. For example, increased attention to the needs of female Veterans has enabled broad access to basic reproductive health services; however, access to more advanced services is variable by location, and VA health care workers noted that additional steps could be taken by providers to ensure that female Veterans feel respected while receiving care in VA facilities.

Some variation in performance across regions and VA facilities may be inevitable because of differences in patient characteristics. In addition, some localized strategies for improvement may not scale up well because of contextual factors. However, these findings point to opportunities to improve Veteran access to VA care along several dimensions as well as the need to consider alternative standards for measuring access to care.

Assessment of Quality of VA Care

Access to care is only beneficial if high-quality care is provided. VA has long played a national leadership role in the quality measurement arena. The assessment showed that VA health care quality was good overall on many measures and domains compared with non-VA comparators. However, as with access to care, quality performance was uneven across VA facilities, with many opportunities for improvement.

The findings of previous studies of quality of care provided in VA settings compared with non-VA settings vary by quality domain. Studies of safety and effectiveness indicated mixed performance, with 22 of 34 studies of safety and 20 of 24 studies of effectiveness showing that quality of care was the same or better in VA facilities. Only five articles assessed patient-centeredness, but all demonstrated better or same VA care quality compared with care in non-VA settings. Four articles assessed equity in VA settings, with one showing better performance, two showing same performance, and one showing worse performance compared with non-VA settings. The nine articles evaluating measures of efficiency, such as hospital length of stay, demonstrated mostly mixed or worse performance in VA facilities compared with non-VA facilities, although two studies showed better performance. Only one study assessed timeliness of care in VA facilities, and it showed worse performance than the non-VA facilities.

There is substantial variation in quality measure performance across VA facilities, indicating that Veterans in some areas are not receiving the same high-quality care that other VA facilities are able to provide. For example, there was a 21-percentage-point difference in FY 2014 performance between the lowest- and highest-performing VA facilities on the rate of eye exams in the outpatient setting for patients with diabetes. Although this variation is lower than that observed in private-sector health plans, a high-priority goal for VA leadership should be narrowing these gaps to ensure that quality of care is more uniform across VA facilities so that Veterans can count on high-quality care no matter which facility they access.

VA outpatient care outperformed non-VA outpatient care on almost all quality measures. VA hospitals performed the same or better than non-VA hospitals on most inpatient quality

measures, but worse on others. VA performed significantly better, on average, on almost all 16 outpatient measures when compared with commercial, Medicare, and Medicaid HMOs. On average, VA hospitals performed the same or significantly better than non-VA hospitals on 12 inpatient effectiveness measures, all six measures of inpatient safety, and three inpatient mortality measures, but significantly worse than non-VA hospitals on two effectiveness measures and three readmission measures.

On most measures, Veteran-reported experiences of care in VA hospitals were worse than patient-reported experiences in non-VA hospitals. Average VA facility-level performance was significantly worse than non-VA facilities for six of ten patient experience measures, including communication with nurses and doctors.

VA uses many systems for monitoring quality. VA currently uses multiple quality monitoring systems—tailored for different care settings and audiences—to collect and report information about the health of Veterans and the care provided to them. Among these systems is ASPIRE, which is part of the VA Transparency Program, which offers publicly available information on the VA Hospital Compare website about how VA is performing relative to other health care organizations across the country. ASPIRE presents information about all aspects of quality, including preventive care, care recommended for acute and chronic conditions, complications and outcomes of care, and patient-reported measures of health care experiences at the national, regional, and local levels of the VA system. In addition to ASPIRE, VA has more than 500 other quality measures that can be used to monitor quality of care regionally and locally and to inform quality improvement projects.

There were mixed opinions on the impact of VA's many quality measures. In interviews, VA administrators and several health care workers noted that attention to quality measurement has led to positive changes in care delivery, for example, by using quality data to identify high-risk patients for more-intensive case management or to initiate patient education in response to high readmission rates. However, several respondents felt that measuring quality did not always have a positive effect on how facilities deliver care. Some noted that the current list of access and quality measures is "just too long" and the measurement process is a burden for VA providers and other staff members.

This level of variation in performance across VA facilities suggests that significant opportunities exist to improve access to care in VA through systematic performance improvement. These findings suggest that a systematic effort is needed to identify and eliminate unwarranted variation, and to develop and encourage the use of best practices to improve performance across the VA system.

Improving Access for Veterans

Looking to the future, the size, demographics, and health needs of the Veteran population, as described by Assessment A, will change. VA will need to adjust its resources and capabilities to meet the changing demand for services among Veterans. VA combines its resources and capabilities to generate the supply of health care services available to enrollees. Access to care, particularly the timeliness of care, is determined in large part by whether the overall level and geographic distribution of supply is well aligned with Veterans' needs. To provide insight into

potential challenges to ensuring timely access, we compared projected supply with projected demand in FY 2019 under several scenarios, including (1) an increase in the number of VA providers but no change in productivity; (2) an increase in productivity with no change in the amount of resources; and (3) changes in both resources and productivity.

VA forecasts an increase in demand for VA care by FY 2019. VA's EHCPM forecasts a 19-percent increase in demand for VA health care services nationally from FY 2014 to FY 2019, due to a projected 5.1-percent increase in enrollment and the aging of enrollees. Although the forecast assumes that the number of Veterans will decrease, a growing proportion of Veterans are enrolling in VA health care (Milliman Inc., 2014), and the EHCPM model includes an assumption that this trend will continue through FY 2019. While the EHCPM is used by VA for planning purposes, it is possible that its predictions of increased demand for VA health care services will be inaccurate. Estimates from Assessment A suggest that the number of patients using VA health care services is expected to increase through 2019, then decrease thereafter.

Assuming that the EHCPM demand forecast is accurate, VA will face challenges in meeting demand under current provider growth trends. Given the caveats noted above, our projections under our first supply scenario (increase in the number of providers) indicate that, if the supply of VA providers continues to increase at historical growth rates, and other resources grow in proportion so that providers continue to deliver a similar amount of health care (that is, no increase in productivity), it will be more difficult for VA to meet the demand for services and provide adequate access to Veterans in FY 2019. These challenges will be more acute in some regions and at some VA facilities than others, so considerations of distribution will be as important as consideration of levels.

Substantial increases in the productivity of existing resources will be needed to meet projected demand. Our second supply projection considers the effect of increasing productivity of each specialty in each administrative parent to benchmark levels—25th, 50th, or 75th percentile of the FY 2014 productivity distribution. Our projections indicate that, if productivity were increased to at least at the 75th percentile for each specialty at each administrative parent, VA would be able to produce enough health care services to meet projected demand. However, such a large increase in productivity would likely be very difficult to achieve.

If both the number and productivity of resources are increased, VA can produce enough supply to meet projected demand. The third supply projection considers the effect of combining increases in the number of providers and the productivity of resources. We found that, if historical hiring trends were to continue and productivity were raised to the 25th percentile of the FY 2014 distribution, the supply produced in FY 2019 would exceed the projected demand. While the overall level of supply is sufficient to provide timely access to care, there are some VISNs in which demand is expected to exceed supply. As such, Veterans in some regions could experience access problems, indicating a need to redistribute supply across geographic areas to meet all enrollees' health care needs.

Changes in policy can help ensure Veterans' continued access to VA care. Comparing options with a policy objective of increasing Veterans' access to care within the VA system, we found that, of the options we considered, the three with the highest estimated impact on access are formalizing full nursing practice authority, increasing the number of VA physicians, and

expanding virtual access to care. None of these options are mutually exclusive; they could be combined in a number of different ways. Each of these options has different potential barriers that present tradeoffs. The primary barrier to formalizing full nursing practice authority is political (key stakeholder opposition); the barriers to hiring physicians are related to cost and administrative challenges associated with the hiring process; and the primary barrier to expanding virtual access to care is cost.

Options with a policy objective of increasing access outside VA system have considerable uncertainty related to potential impact on access. Greater collaboration with and reliance on private-sector health care organizations to enhance VA capacity to provide timely access to care will be crucial to the success of these options. One option—consolidating existing purchased care programs—has the most certain impact. The current system of overlapping programs was widely cited as problematic and does not have any clear benefits. This option is discussed in greater detail in Assessment C.

The impact and feasibility of increasing non-VA resources available for Veterans' health care would be highly dependent on the scope of the change. Shifting certain types of services from VA to purchased care could potentially improve both access and quality of care, but doing so could also increase challenges in care coordination. Shifting a greater share of services from VA to purchased care would require more fundamental changes to VA. The TRICARE program could serve as a model for an option to restructure VA as a purchaser rather than provider of health care, and, indeed, its relative success within DoD highlights the potential of such an option. However, our analyses indicate that many Veterans without access to VA health care also face significant barriers to accessing purchased care, including distance and cultural barriers. Thus, the option to transform VA from a provider to a purchaser of health care would not necessarily have a significant positive impact on access.

Conclusions

The assessment highlights many opportunities to improve VA capabilities to provide timely and accessible care. We identified a large number of barriers to effective use of VA resources. We also found widespread variation in performance across VA facilities. We did not find evidence of a system-wide crisis in current access to VA care. However, our projections indicate that, without changes, it will be increasingly difficult for VA to provide good access to care for our nation's Veterans.

This assessment has several important limitations, a number of which stem from the fact that the assessment was conducted over a very short time frame. The lack of direct input from Veterans is key. To address this limitation, we conducted analyses of secondary data sources that included Veterans' perspectives, as well as interviews with representatives of Veterans Service Organizations. Another limitation is that the projections of future resources are based solely on provider and productivity data and do not directly include changes in other key resources, such as physical space, equipment, and IT. Moreover, our projection analysis does not account for changes in demand that might occur if supply, and thus access, was increased. A projection model that included all resources and the interactions between them (for example, system dynamics) was beyond the scope of this assessment. Differences between VA and other

health care organizations, in terms of both the organization of the delivery system and the patient population, limit the value of comparisons between VA and non-VA health care organizations. Therefore, in most cases, we used qualitative data from interviews and literature reviews to assess the adequacy of VA's resources and capabilities.

Recommendations for Consideration

Based on the findings of Assessment B, we make several recommendations to improve access to care for Veterans.

VA should use a systematic, continuous performance improvement process to improve access to care. Although many VA facilities achieve very high levels of performance on key access and quality measures, there is also a great deal of variation across the system. A systematic effort is needed to identify unwarranted variation, identify and develop best practices to improve performance, and embed these practices into routine use across the VA system. Some of the best solutions may be developed locally to reflect local needs and contexts. Solutions should be designed to be responsive to Veterans' preferences, needs, and values.

VA should consider alternative standards of timely access to care. Timeliness standards should be reexamined. VA should examine the utility of existing alternative benchmarks, such as same-day availability of the third next available appointment. Access standards for other dimensions, such as cultural access, should also be developed and used in performance monitoring and improvement. VA should develop methods to routinely compare the timeliness of VA care with non-VA benchmarks and publish these comparisons for transparency.

VA and Congress should develop and implement more sensitive standards of geographic access to care. VA should compare the "one-size-fits-all" approach of driving distance to alternative standards that are more sensitive to differences between Veteran subgroups, clinical populations, geographic regions, and individual facilities. This assessment highlighted the importance of time spent driving, mode of transportation, traffic, and availability of needed services as key considerations in assessing geographic access to care.

VA should focus efforts to increase Veterans Choice Program utilization in areas with the lowest rates of geographic access to VA facilities. These areas can be identified in geographic assessments that consider locations of facilities relative to enrollee populations, along with estimates of access to more complex and specialized service offerings in VA facilities.

VA should continue moving toward using a smaller number of quality metrics in quality measurement and improvement activities. VA maintains an extensive set of quality measures. Although use of these measures has led to improvements in care, the proliferation of measures creates burdens on staff and resources and can lead to emphasis on the measures rather than improvement in areas of care that are more likely to improve patient outcomes. VA has already

moved toward reporting systems that rely on a smaller number of measures, such as Strategic Analytics for Improvement and Learning (SAIL).[2]

VA should take significant steps to improve access to VA care. Our projections indicate that increases in both resources and the productivity of resources will be necessary to meet increases in demand for health care over the next five years. The options we considered that have the highest estimated potential impact are formalizing full nursing practice authority, increasing physician hiring, and increasing the use of virtual care. These are commonly proposed options for increasing access to VA care. In addition, new models of health care delivery are emerging rapidly in the U.S. health care system that could improve access to care. VA should seek to be an early adopter of these new models and should build a strategy that enables and supports such innovation.

VA should establish itself as a leader and innovator in health care redesign. Our assessment found that VA has historically been on the leading edge in several important areas, such as development and use of health IT. It is also on the forefront on many other innovative delivery methods, such as team-based primary care. As a large integrated delivery system, VA is well placed to innovate in comparison with many other U.S. health care delivery systems. It should endeavor to maximize this opportunity, given the constraints associated with being a public entity (for example, hiring processes, salaries, budgeting). VA should also endeavor to learn from current leaders in areas where its leadership position has eroded, particularly in health IT, and seek to reestablish its leading position.

VA should streamline its programs for providing access to purchased care and use them strategically to maximize access. Currently available programs are overlapping and confusing to Veterans and VA employees as well as non-VA providers. VA should clearly identify the objectives of purchased care access and streamline programs to meet those objectives.

VA should systematically identify opportunities to improve access to high-quality care through use of purchased care. Some types of care may be more effectively and efficiently delivered by non-VA providers. Identification of these types of care and the impact of shifting care to non-VA providers requires an in-depth systematic analysis that was beyond the scope of this assessment.

These recommendations would help VA improve Veterans' access to care across the VA system and ensure that future demand for VA care can be met. Although this assessment did not find a system-wide crisis in access to VA care, it did identify a high degree of variability in performance across VA facilities, a number of barriers to effective use of VA resources and capabilities, and likely future challenges. These recommendations should be implemented and progress regularly evaluated to ensure continuous improvement in performance. Such improvement will be needed to ensure that we meet our nation's commitment to care for Veterans.

---

[2] Although SAIL uses fewer measures to simplify reporting, they are composite measures which still incorporate numerous individual performance measures.

1   Introduction

1.1   Background

Access to quality health care is a central part of our nation's commitment to Veterans. In February 2014, a recently retired Department of Veterans Affairs (VA) physician alleged that at least 40 Veterans died while waiting for care at the Phoenix VA Health Care System. While the allegations of deaths were not proven, this raised questions about how effectively the commitment to Veterans was being fulfilled (VA, Office of Inspector General, 2014). Does VA have the resources and capabilities to ensure that Veterans have access to the health care they need? What is the best way to ensure that Veterans' needs are met?

Following the Phoenix allegations, the VA Office of Inspector General investigated the timeliness of VA health care, finding that wait lists for appointments were being used inappropriately. Some VA staff regularly entered false information regarding patients' preferred dates of care to minimize reported wait times between the preferred date and the actual date of appointments. They kept paper lists of patients for days or weeks before adding them to the official electronic wait list. The Inspector General also pointed to systemic issues within VA that may limit Veterans' access to care, including lack of available appointments within certain clinical specialties and problems with care transitions for patients discharged from mental health services.

The Phoenix allegations focused a strong spotlight on Veterans' health care. However, accessibility and timeliness of care are longstanding areas of concern within VA. Just in the past decade, there were 20 other reports similar to the VA Inspector General's 2014 report, as well as a series of U.S. Government Accountability Office (GAO) reports addressing time spent waiting for health care, physician staffing levels, and other issues related to health care access. VA has many ongoing programs and initiatives to increase access to care for Veterans, including programs to give Veterans access to non-VA health care providers.

The Veterans Choice Act was passed to address these issues and to provide other short-term improvements in Veterans' access to care. The Veterans Choice Program expanded VA authority to furnish care to Veterans through agreements with non-VA providers. Veterans are eligible for the Veterans Choice Program if they are unable to schedule an appointment within 30 days of their preferred date or live more than 40 miles from a VA medical facility. The Veterans Choice Act includes a number of other provisions designed to increase access to VA and non-VA providers, including improved access to telemedicine through mobile medical centers; 27 new major medical facility leases; increased transparency of performance data on VA providers, including wait times; new residency and other training and education programs; and recruitment and appointment of personnel in occupations identified by the VA Inspector General as having the greatest shortages. The law includes appropriations for VA to support these activities.

Section 201 of the Veterans Choice Act includes a requirement for an independent assessment of VA health care addressing 12 specific questions (denoted A through L, based on the legislative language). This report addresses Assessment B, which the Veterans Choice Act

describes as "an independent assessment of the current and projected health care capabilities and resources of VA, including hospital care, medical services, and other health care furnished by non-VA facilities under contract with VA, to provide timely and accessible care to Veterans" (Veterans Choice Act, Section 201).

1.2   Objectives

The objectives of this report are to assess VA's current and projected resources and capabilities, the level and nature of access to VA care, and barriers and facilitators to access. Against this background, we then explore how selected policies could affect Veterans' access to high-quality care. Specifically, we address the following research questions:

- What are VA's current resources and capabilities in key domains?
- What are current levels of access to VA care?
- What is the quality of care in VA?
- What are VA's projected resources and capabilities to provide timely and accessible care, and how might different policy options enhance VA's resources and capabilities for treating Veterans in the future?

1.3   Scope

We defined key types of health care resources and capabilities, as described in Subsection 1.4. Some types of health care resources are examined in greater detail by other Section 201 assessments. In areas of overlap, we coordinated with the other assessments, providing an overview in this report with reference to more detailed discussions in the other assessment reports.

The following bullets summarize the other assessments conducted as part of this project:

- Assessment A: Current and projected demographics and unique health care needs. We used VA's projections of Veteran demand for health care services to analyze how VA resources and capabilities to provide access to care would change under different policy scenarios. Assessment A discussed VA's demand projections, arrived at an independent projection of how the Veteran population and its unique health care needs will change in the future, and examined how future demand for VA health care could change under different policy scenarios.
- Assessment C: Authorities and mechanisms for care at non-Department facilities. We discussed current VA resources and capabilities to provide access to care under contract and purchased from non-VA entities, and discussed policy options to improve access through greater use of purchased care. Assessment C described the authorities and mechanisms to provide purchased care in detail. While Assessments B and C used similar data to describe purchased care use, Assessment C described policy options to change VA authorities and mechanisms to purchase care in greater detail.
- Assessment D: System-wide access standard. In our assessment of access to VA care, we used access standards in use by VA and compared these with available private-sector

standards. Assessment D performed a more systematic review of standards for access, scheduling, and wait times. (The results of this review were not available while we were conducting our analysis).

- Assessment E: Workflow process for scheduling. We included scheduling as one type of capability studied. Assessment E assessed VA scheduling processes in greater detail.

- Assessment F: Organization, workflow processes, and tools to support inpatient care. Clinical workflow is one type of barrier to access considered in our analyses. Assessment F assessed VA systems and processes that support care delivery within the hospital setting in greater detail.

- Assessment G: Staffing levels at medical facilities: Both Assessments B and G used VA data to estimate provider counts and productivity for physicians and associate providers in the VA system. Assessment G processed and made these data available to Assessment B. Assessment B included estimates of provider counts and productivity for therapists (for example, physical therapists and occupational therapists), which Assessment G did not. Assessment B combined these data with wait-time and interview data to estimate the specialties with capacity constraints and to identify factors affecting capacity. Assessment B also estimated VA enrollees' geographic access to non-VA physicians and estimated potential capacity constraints of those physicians.

- Assessment H: Information technology strategies. We studied VA IT resources and capabilities that directly impact Veteran access to care. Assessment H focused on VA IT in greater detail from the strategy and management perspectives.

- Assessment I: Business processes of the Veterans Health Administration (VHA): Assessments B and I analyzed some common data on purchased care spending. Assessment I assessed processes related to purchased care, such as the accuracy and timeliness of VA payments to vendors and providers, as well as revenue collection for VA provided care.

- Assessment J: Purchasing, distribution, and use of pharmaceuticals, supplies, and devices: We included medical technology and supplies as one type of resource used by VA, while Assessment J focused in more detail on purchasing, distribution, standardization, and use of pharmaceuticals, supplies, and devices.

- Assessment K: Construction and maintenance projects at medical facilities. We included physical infrastructure as one type of VA resource and analyzed geographic access to VA facilities. Assessment K evaluated VA processes to deliver medical facilities, including capital management, construction, leasing, and maintenance.

- Assessment L: Competency of leadership. We did not directly study leadership, but we recognize that it affects the resources and capabilities we studied. Assessment L directly assessed VHA leadership.

1.4   Definitions of Key Concepts

Access to care has been defined in conceptual models that are widely used in research and other assessments of access. Similarly, definitions and frameworks of health care quality and

organizational capacity, resources, and capabilities have been developed. We drew on these frameworks to define the key concepts that are the foundation of Assessment B.

1.4.1   VA Resources and Capabilities

The VA system includes a wide range of health care capabilities that draw on resources owned or leased by VA, as well as resources under contract and purchased from non-VA entities.

Resources are assets that VA can use to provide access to care for Veterans. Important resources include the financial means to support health care for Veterans, human resources, facilities, relationships with other organizations to provide care, and IT (Table 1-1).

Capabilities are the ability of VA to use its resources in coordinated tasks to provide access to care for Veterans (Helfat & Peteraf, 2003). The fact that VA has a resource does not necessarily mean that the resource is used effectively to enable a capability to provide access to care. For example, VA may have a certain number of facilities staffed by cardiologists, but only some of those facilities may have the capability to provide some specialized cardiology services.

Table 1-1. Types of VA Health Care Resources

Types of Resources	Definition
Fiscal	Funding sources and allocations, as well as alternative sources of finance, operating budget, and capital (for example, VA budget allocations).
Workforce and human resources	The employees who support and provide health care for Veterans (for example, physicians, nurses, clinical support staff).
Physical infrastructure	The physical structure needed to support provision of care (for example, medical centers, outpatient clinics, medical equipment).
Interorganizational relationships	Relationships with other organizations that VA can use to improve Veterans' access to care (for example, the Veterans Choice Program).
IT	Information and information technology (IT) resources such as computing and IT equipment, IT support, and databases (for example, patient portals, electronic health records, telemedicine).

Source: Adapted from Meyer et al., 2012.

1.4.2   Access, Timeliness, and Quality

A broad definition of **access** is "the fit between the individual and the health care system" (Fortney et al., 2011; Penchansky & Thomas, 1981). Put another way, Veterans' access to health

care depends on how well the health care system addresses patient needs. Both the characteristics of the health care system and the characteristics of the individual are important in determining this match. For example, can a Veteran with diabetes see a podiatrist before poor foot care leads to infection and possible limb amputation? Can a Veteran with endometriosis and symptomatic anemia have access to a gynecologist for surgery? Does a Veteran with posttraumatic stress disorder (PTSD) have access to psychotherapy with a provider trained in evidence-based treatment for PTSD?

Access to health care services does not automatically translate into actual service use. Veterans may have excellent access to care that, in theory, fits their needs, but they may or may not take advantage of available care to use health care services. Access to care is a prerequisite for use, however, and therefore a key factor affecting Veterans' health and experiences of care.

Access is a general concept that subsumes more specific aspects of the fit between individuals and the health care system (Penchansky & Thomas, 1981). **Timeliness** is a dimension of access focused on how promptly needed care is available (Fortney et al., 2011). The allegations at the Phoenix VA Health Care System focused on time spent waiting for health care appointments, one aspect of timeliness. Our assessment team defined *untimely care* as delays in care that put Veterans at risk of poor health outcomes, either because symptoms are not resolved in a time frame compliant with VA guidelines or because delays cause patients not to follow up with treatment. Delays in care that could put Veterans at risk of death or other poor health outcomes are clearly harmful in a clinical sense. However, even if delays do not directly change patient outcomes, they may be important from the Veteran's perspective. For example, time spent in a waiting room could lead to missed time at work or with family, and long waits for appointments could cause anxiety.

Timeliness of care means different things for Veterans with different health care needs. For example, consider three scenarios:

- A Veteran seeks to enroll in VA health care and establish a relationship with a primary care physician. How long does it take for the Veteran to enroll? How much time elapses between enrollment and the first visit to the primary care physician?

- Following the first visit, the Veteran is referred to a cardiologist and a dermatologist for consultation on two specific health problems. How long is it before the Veteran sees these specialists?

- As a result of these visits, the Veteran requires ongoing care that must be closely coordinated between the primary care provider and the specialist physicians. When the Veteran arrives at the next primary care appointment, will the relevant information from the specialist visits be available to the primary care physician?

In this report, we examine available data on the timeliness of VA health care. Other dimensions of access are listed in Table 1-2. These dimensions—including geographic access to health care providers, financial considerations, digital connectivity, and the cultural acceptability of health care—are vital in ensuring that health care is accessible to Veterans. We did not assess VA's current eligibility structure because our assessment scope was resources and capabilities to provide care, not eligibility for benefits.

Table 1-2. Dimensions of Access to Health Care

Dimensions of Access	Definition
Geographic	The ease of traveling to health care providers. For example, how far does a Veteran live from needed health care services? How long does it take to travel to appointments? Is it possible to take public transportation, and if so, how long is spent in transit?
Timely	The ability to obtain care and get it promptly. For example, when are Veterans able to schedule appointments for needed care? How long do they wait during health care visits?
Financial	Eligibility for VA services and the cost of VA services. For example, how much do Veterans pay out-of-pocket for VA health care services?
Digital	Connectivity enabling digital communications with providers, caregivers, peers, and computerized health applications. For example, do Veterans own or have the right to use digital channels of communication?
Cultural	The acceptability of health services to the patient. For example, can Veterans receive services in a language in which they are comfortable communicating? For a Veteran with a stigmatizing illness, are services offered by providers whose behavior does not cause the Veteran to feel discriminated against?

Source: Derived from Fortney et al., 2011.

The **quality** of health care services is critical to understanding access to care, since access is beneficial only if adequate quality care is provided. The Institute of Medicine has defined six dimensions of health care quality (Table 1-3): Care should be safe, timely, equitable, effective, efficient, and patient-centered (Institute of Medicine, 2001). In this report, we examine the quality of VA health care in comparison with non-VA care as measured in previous studies and by analyzing more recent VA performance data.

Table 1-3. Dimensions of Health Care Quality

Dimension of Quality	Definition
Safe	Avoiding injury to patients from the care intended to help them. For example, do hospitalized patients develop avoidable infections?
Timely	Reducing wait times for both providers and patients. For example, are stroke patients treated quickly?
Equitable	Providing care that does not vary in quality because of personal characteristics such as gender, race/ethnicity, and socioeconomic status. For example, is a heart attack diagnosis more likely to be missed in women than men?

Dimension of Quality	Definition
Effective	Providing evidence-based services to those who could benefit, and not giving services to those unlikely to benefit. For example, do patients with diabetes receive recommended screening?
Efficient	Avoiding waste, including waste of equipment, supplies, ideas, and energy. For example, are duplicate unnecessary medical tests provided to the same patient?
Patient-centered	Providing care that is responsive to individual patient preferences, needs, and values. For example, how well do health care providers communicate with patients?

Source: Institute of Medicine, 2001.

1.5   Improving Access for Veterans

The Veterans Choice Act aims to improve access to VA care in the short term. However, longer-term solutions are also needed to ensure that VA is positioned to meet Veterans' needs in the future. Over time, the size, demographics, and health needs of the Veteran population will change. VA will need to adjust its resources and capabilities to meet the changing demand for services and to select appropriate policies to meet demand. VA has a number of options. For example, some policy options for ensuring access to health care focus on increasing the number and type of resources that VA owns or that it purchases from the private sector. Other policy options for ensuring access to health care seek to improve the productivity of VA's existing capabilities to provide care (for example, by formalizing task assignments in outpatient clinics to improve clinic workflow). These are selected examples among many proposed options for improving the nation's ability to fulfill its commitment to Veterans. We assess a number of policy options designed to improve access, providing information on the expected impact on access, fiscal considerations, operational feasibility, stakeholder acceptability, and the tradeoffs among them.

1.6   Organization of Report

The remainder of this report consists of six sections:

- Section 2 provides an overview of the methods used in the assessment.
- Section 3 provides an assessment of five types of resources and capabilities: fiscal, workforce and human resources, physical infrastructure, interorganizational relationships, and IT.
- Section 4 provides an assessment of access to VA care along five dimensions: geographic, timely, financial, digital, and cultural.
- Section 5 provides an assessment of the quality of VA care, using the six domains outlined by the Institute of Medicine: safety, timeliness, equity, effectiveness, efficiency, and patient-centeredness.

- Section 6 discusses approaches VA could use to adjust resources and capabilities to improve access for Veterans.
- Section 7 describes our conclusions and recommendations.

The report also includes nine appendices, five of which are included in a separate document:

- Appendix A: Methods
- Appendix B: Survey
- Appendix C: References
- Appendix D: Acronyms
- Appendix E: Summary of Qualitative Interviews
- Appendix F: Supplementary Access Materials
- Appendix G: Supplementary Quality Materials
- Appendix H: Projections
- Appendix I: Survey Data Tables.

2 Overview of Methods

2.1 Introduction

In this section, we provide an overview of the mixed-methods approach we used to assess VA's current resources and capabilities, the level and nature of access to VA care, barriers to and facilitators of access, the quality of care, and policy options for enhancing VA resources and capabilities. We collected data through literature reviews, key informant interviews, a survey of VA administrative parent organizations, and from VA and non-VA data sources.[3] We conducted analyses of the data and other secondary sources, including VA and other data sources, to inform the assessment.

In addition, we selected seven "illustrative clinical populations" to provide a more detailed understanding of VA capabilities, resources, and accessibility in selected subpopulations of Veterans. We analyzed these to supplement analyses of VA as a whole in areas where overall analyses are too broad to provide a sufficient understanding of relevant issues.

We also developed a method for projecting future resources to compare with forecasted changes in patient demand for VHA treatment to identify potential gaps. To support analyses of future options for VA to address identified gaps, we used a multipronged approach to identify and analyze a reasonable range of feasible policy options to enhance VA's ability to provide timely and accessible care to Veterans.

This section provides a high-level discussion of the specific methods used in Assessment B, as follows:

- Subsection 2.2: Illustrative Clinical Populations
- Subsection 2.3: Literature Reviews
- Subsection 2.4: Interviews
- Subsection 2.5: 2015 Survey of VA Resources and Capabilities
- Subsection 2.6: Data Sources and Measures
- Subsection 2.7: Data Analyses
  - Resources and Capabilities (Subsection 2.7.1)
  - Access to Care (Subsection 2.7.2)
  - Quality of Care (Subsection 2.7.3)
- Subsection 2.8: Assessing Options for Enhancing VA Resources and Capabilities
  - Future Policy Options (Subsection 2.8.1)

---

[3] According to the VHA Handbook (VA, 2013b) an administrative parent is defined as a collection of all the points of service that a leadership group (Medical Facility Director, Deputy Medical Facility Director, Chief of Staff, Associate or Assistant Director, and Nurse Executive) manages. The points of service can include any institution where health care is delivered. All the data originating from these points of service roll up to a single station number representing the administrative parent for management and programmatic activities.

○ Projecting Needed Resources in the Future (Subsection 2.8.2).

Additional information about methodology can be found in Appendix A.

2.2   Illustrative Clinical Populations

To provide a more detailed understanding of VA capabilities, resources, and accessibility in selected subpopulations of Veterans, we selected seven "illustrative clinical populations." We conducted analyses focused on these clinical populations to supplement analyses of VA as a whole in areas where overall analyses are too broad to provide a sufficient understanding of relevant issues. In the analyses of the illustrative clinical populations, we identified the resources needed to treat these populations (for example, types of providers, infrastructure, equipment) and conducted analyses assessing the level of those resources. We measured geographic access to specific services needed by these populations. In addition, the 2015 Survey of VA Resources and Capabilities was designed to provide information specifically about these populations and to identify points in the care process where they may face delays.

We selected the seven illustrative clinical populations to ensure that the portfolio of populations considered in these analyses reflects populations of particular interest to VA (for example, high prevalence, congressional focus, service connection) and is diverse on important characteristics. We defined a clinical population as a group of individuals with a need for specific health care resources. Therefore, a clinical population could include individuals with certain clinical conditions (for example, type II diabetes mellitus, PTSD) or individuals who have received a certain type of medical treatment (for example, who are in need of gynecological surgery). The seven populations selected are Veterans with acute coronary syndromes, colon cancer, PTSD, substance use disorder (SUD), traumatic brain injury (TBI), type II diabetes mellitus, and women's diagnoses requiring gynecological surgical intervention.

We selected clinical populations by applying screening criteria to each candidate population and applying breadth criteria to a subset of populations that met the screening criteria. We defined the screening criteria as follows:

1. **Importance:** Selected clinical populations should be "important," defined as being of particular interest to those seeking to understand VA resources and capabilities, including populations that are either unique to or disproportionately prevalent in the Veteran population. The importance may be due to high prevalence, high costs, or high visibility (that is, listed as VA priorities or which have received specific public, congressional, or legislative attention).

2. **Measurability:** Selected clinical populations should be feasibly identified in the VA population using International Classification of Diseases-9 codes in a reliable and valid manner (subject to limitations of administrative data due to variation in coding practices). This allows for analyses of encounter data to illustrate access-related issues in the selected populations.

We defined the breadth criteria to ensure diversity along the following dimensions:

1. **Type of care:** Medical and behavioral health care services should be represented, as should health care services required to treat service-connected disabilities.

2. **Acuity:** The care required by the selected populations should vary in the level of urgency, covering the range of preventive care, routine chronic illness care, and urgent acute care.

3. **Care setting:** The services typically used by the selected populations should be provided in a variety of health care settings (for example, acute care hospitals, emergency departments, outpatient primary care clinics, outpatient specialty care clinics).

4. **Workforce:** A variety of types of providers who typically treat the selected clinical populations should be represented, including specialists and generalists; medical, surgical, and behavioral health care providers; ancillary staff; and providers who work in teams.

5. **Population diversity:** The conditions should reflect population diversity (sex, age).

We applied the screening criteria using a two-step process. First, to identify important and measurable clinical populations, we selected the 37 conditions identified by the VA–Department of Defense (DoD) Reporting & Analysis Datamart Technical Advisory Group as high-interest groups. We used prevalence data provided by the VA Healthcare Analysis and Information Group to select the 10 most prevalent medical high-interest groups, the five most prevalent behavioral health high-interest groups, and all conditions that were primarily attributable to military service. The result was the 20 populations listed in Appendix A, Table A-1. We made some adjustments to the initial list of 20 populations before applying the breadth criteria to eliminate some populations that were too broad and to meet the population diversity criterion (which required the addition of a population composed mainly of women). Based on input from VA experts in women's health, we included the category of conditions that require gynecologic surgery. We then used the breadth criteria to select six additional clinical populations from the set of 20 to provide the desired diversity of characteristics. In Table 2-1, we list the seven selected clinical populations and describe them based on the breadth criteria.

Table 2-1. Description of How Selected Populations Contribute to Breadth Criteria

Clinical Population	Description of Contribution to Breadth Criteria
Acute coronary syndromes	Acute inpatient care, emergency department care, and chronic illness care. Specialty workforces (cardiology, cardiovascular surgery, emergency medicine, interventional radiology) play a substantial role.
Conditions requiring gynecologic surgery	Surgical conditions. Can be inpatient or outpatient surgery. Specialty workforce (gynecologists, operating room staff trained in gynecologic surgery). Population diversity (women).

Clinical Population	Description of Contribution to Breadth Criteria
Type II diabetes	Primarily routine outpatient care for management of chronic condition. Some acute exacerbations. Primary care workforce, occasional specialty care (endocrinology, nutrition, podiatry, ophthalmology). Often managed by a team.
Colon cancer	Time course is sub-acute, but timeliness of care is particularly important. Infrastructure needs include outpatient clinics, inpatient hospital care (sometimes semi-elective), surgical facilities, and specialized outpatient facilities (for example, chemotherapy, radiation therapy). Primary care for screening and sometimes diagnosis. Specialty workforce (for example, oncology, surgery, radiation therapy) needs predominate after diagnosis.
TBI	Often service-connected. Interdisciplinary, rehabilitation-focused care. Population diversity (younger Veterans). Workforce (neurologists and physical medicine and rehabilitation, and pain specialists).
PTSD	Usually service-connected. Primary care and outpatient specialty mental health; some specialized residential PTSD programs. Workforce includes psychiatrists and psychologists trained in evidence-based psychotherapy for PTSD. Treatment can be delivered via telemental health.
SUD	Chronic condition with acute exacerbations. Primarily outpatient care in primary care, specialty care, or specialty substance abuse care, but frequent emergency care for a subsection of the population. Residential rehabilitation (for example, domiciliary, residential treatment) plays a substantial role; inpatient detoxification services. Some medications are either expensive (injectable naltrexone) or difficult to access (methadone, buprenorphine, injectable naltrexone).

2.3 Literature Reviews

The Assessment B team conducted several literature reviews to provide background and context for the assessment. For each type of resource (for example, fiscal, physical infrastructure), we conducted a targeted literature review to identify information about current levels, trends over time, and key issues and concerns. We also conducted formal, in-depth systematic literature reviews to assess the evidence related to access, quality, and potential policy options for enhancing VA's resources and capabilities.

2.3.1 Targeted Literature Reviews

The targeted literature reviews in each resource area included both the peer-reviewed and gray literature. We developed search terms for each type of resource and searched databases such as PubMed and GreyLit. We reviewed the articles and reports returned by the search and abstracted relevant information. We incorporated data from the literature review into the

analyses of current levels of resources, geographic variation, trends over time, and key issues or concerns. Example questions, sources, and example search terms are shown in Table 2-2.

Table 2-2. Key Questions and Search Terms Used in Targeted Literature Reviews

Resource Category	Sample Questions	Data Sources	Example Search Terms
Fiscal	▪ How does VA develop its budget? ▪ How does VA allocate the funds it receives from Congress? ▪ What are the challenges associated with VA's funding processes and what are the consequences? ▪ How do VA funding and expenditures on medical care compare with the private sector?	▪ PubMed ▪ GreyLit ▪ Congressional testimony	▪ Veterans Administration and: ▪ Budget, expenditure, resource allocation
Workforce and Human Resources	▪ How does VA assess and plan current and future workforce capacity? ▪ What are the observed and perceived constraints on workforce capacity within VA's system? ▪ What factors affect the capacity of the VA workforce? ▪ What types of approaches does VA use to expand workforce capacity?	▪ PubMed ▪ Google Scholar ▪ Grey Literature Report ▪ VA documentation	▪ Veterans Administration and: ▪ Workforce, staffing, human resources, manpower, personnel, scheduling ▪ Physician, nurse, hospitalist, hospital staff, doctor, clinician ▪ Personnel selection, recruit, retention, turnover, burnout, retain ▪ Capacity, capability, productivity, efficiency,

Resource Category	Sample Questions	Data Sources	Example Search Terms
			relative value scales, practice management
Physical Infrastructure	▪ What proportion of a population of Veterans is within a certain distance or travel time from a facility or care? ▪ What are barriers or facilitators to geographic access to health care for Veterans?	▪ Cumulative Index to Nursing and Allied Health Literature ▪ Ovid MEDLINE ▪ PubMed	▪ Veteran and: ▪ Access or geographic or distance or travel ▪ Health or medical or disorder
Interorganizational Relationships	▪ What are the resources and capabilities of non-VA health care organizations to provide additional access to health care for Veterans?	▪ VA and DoD public documents ▪ Reports from the GAO, Congressional Research Service, and VA Office of Inspector General ▪ Congressional testimony	▪ Veterans Administration and: ▪ Purchased care, individual authorizations, Patient Centered Community Care Program (PC3), Access Received Closer to Home (ARCH), Veterans Choice Program, Non-VA Care Coordination, Fee Basis Claims System ▪ Sharing agreements, affiliated academic medical centers, DoD, Indian Health Services, Federally Qualified Health Center (FQHC)
IT	▪ What are the current IT	▪ VA internal	▪ Veterans

Resource Category	Sample Questions	Data Sources	Example Search Terms
	resources and capabilities that VA uses to provide access to care for Veterans? ▪ How do IT resources and capabilities vary across geographic regions and health care facilities? ▪ What are barriers and facilitators to achieving desired levels of IT resources and capabilities in VA?	reports and presentations ▪ PubMed	Administration and: ▪ IT ▪ Clinical video telehealth, VistA (Veterans Health Information Systems and Technology Architecture)/ Computerized Patient Record System (CPRS), data exchange, mobile apps, patient portal, MyHealtheVet

2.3.2 Systematic Literature Reviews

We conducted systematic reviews to assess access, quality, and potential policy options. Systematic reviews follow very rigorous procedures and are intended to provide a comprehensive, in-depth review of the topic under consideration. For these reviews, we followed guidelines outlined in the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Statement (http://www.prisma-statement.org/index.htm). The key steps in these systematic reviews were developing the search strategy (see Table 2-3), selecting studies for inclusion in the review, abstracting data from the selected articles, assessing the quality of the evidence, and synthesizing the results.

Table 2-3. Key Questions and Search/Inclusion Strategies Used in Systematic Literature Reviews

Category	Sample Questions	Search and Inclusion Strategies
Access	▪ How accessible is VA care in each of the dimensions of access outlined by the Assessment B conceptual model of access? ▪ What are the	▪ Search terms included: ○ Veterans and VA health care facilities ○ access (defined as the availability of services) ○ utilization (defined as the use of services) ▪ Searched PubMed for articles between January 1, 2005, and April 10, 2015 ▪ To be included, the article had to evaluate access to care and/or the relationship between access to care

Category	Sample Questions	Search and Inclusion Strategies
	facilitators and barriers to access to care in VA?	- and the utilization of services at VA facilities. - Articles were classified according to characteristics of access outlined by the Assessment B conceptual model.
Quality	How does the quality of care provided by VA compare to that for non-VA health care facilities and systems?	- Started with terms from prior systematic reviews on health care delivered in VA versus non-VA settings (Shekelle, Asch et al., 2010; Kehle, Greer, et al., 2011) - Searched PubMed for articles between January 1, 2005 and January 1, 2015 - To be included, the article had to present a comparison of quality of care in VA and U.S. non-VA settings. - If an article had been included in the previously published systematic review on quality in VA versus non-VA settings, the team used already abstracted data and reviewed the paper to ensure that all dimensions of quality were included. - Articles were classified according to dimensions of quality outlined by the Institute of Medicine.
Policy Options	What are feasible policies or approaches to improving access to care to Veterans?	- Searched PubMed for all English-language articles published from 1995 to present using a broad search strategy combining terms representing VA resources and capabilities and each of the types of VA health care resources shown in Table 1-1 - Also conducted separate targeted searches on policy options raised during key informant interviews, such as contracted care, DoD care, waitlists and scheduling, physician recruitment and hiring and overall access to care, as well as on articles written by specific authors suggested by advisory panel - Searched gray literature for research and policy reports pertaining to timely and accessible care in VA - Articles were abstracted for key findings and recommendations.

Titles and abstracts identified through the search were screened by two team members trained in the critical analysis of literature. An article was selected for full-text screening when both team members agreed it should be included. When differences in the initial assessment (inclusion or not) occurred, the specific abstracts were discussed with at least one other senior member of the Assessment B team.

Each full-text article selected for screening was reviewed by two trained team members using screening forms designed for the review. To be included, the article had to meet inclusion criteria specific to each review. For each article that met the screening criteria, information was independently abstracted by two reviewers using an abstraction form.

Once the forms were completed, all the data were evaluated by the review team, and any discrepancies between reviewers were resolved. Each article was assigned an overall score, based on relevance and quality of statistical methods.

2.4   Interviews

Interviews with VA employees and others with VA expertise addressed questions that could not be answered with sufficient detail by literature review or analysis of quantitative or survey data. Interviews spanned a number of topics and research questions related to VA resources, capabilities, access, and quality, including:

- Types and levels of VA resources
- Barriers and facilitators to increasing levels of resources of different types
- Barriers and facilitators to using resources effectively to provide access to care
- Barriers and facilitators to Veterans' accessing VA care
- Perspectives on quality and access measurement
- Major challenges VA is facing in providing timely and accessible care to Veterans
- Policy options currently being considered and/or evaluated that might help improve VA's ability to provide timely and accessible care
- Feasibility of and potential obstacles to successfully adopting policy options.

2.4.1   Respondent Selection

VA/Expert Respondents. To identify specific offices or individuals within VA that could address the topics outlined above, we searched organizational staffing charts and senior personnel lists supplied by VA, as well as descriptions of the responsibilities of each office available in the 2014 Functional Organizational Manual v2.0a. We identified potential interviewees outside of VA through literature review. These included policy-makers, key stakeholders, and academic and other health care and public policy researchers who authored reports related to VA or health care issues germane to the evaluation of VA capacity.

Facility Respondents. All the topics listed above, with the exception of the policy options topics, required interviews with facility-level personnel. The respondent groups, by facility type, included:

- VA Medical Center (VAMC): Director, Associate Director, Associate Director of Patient Care Services, Chief of Staff, Quality Director, health care providers in seven specialties, paraprofessionals/clinical support staff such as care coordinators, social workers, medical support assistants

- Community-Based Outpatient Clinic (CBOC): Medical Director, nurse managers, health care providers in primary care, behavioral health, and obstetrics/gynecology)
- VISN: Chief Medical Officer, Quality Management Officer, Chief Information Officer.

We drew a purposive sample of VAMCs. We selected the sample to include a variety of facilities that, while not technically representative of the universe of VAMCs, would provide variation on key characteristics. We created six VAMC groups based on three characteristics: capacity, complexity, and metropolitan context. *Capacity* refers to the size of the facility, which was measured in terms of the number of patients served; *complexity* refers to the level of the VAMC's ability to treat a large number of conditions; and *metropolitan context* is the size of the urban area served. Additional information on how we defined these metrics can be found in Appendix A, Subsection A-2.

We began with a list of 150 VAMCs from a September 2014 extract from the VHA Site tracking System that was accurate when we began the selection process in January 2015.[4] We then eliminated some VAMCs from this list of the following reasons:

- Seventeen pairs of VAMCs coreported their statistics in the 2012 Hospital Quality Report Card. Because it was not possible to assign a specific number of visits to each VAMC, we elected to eliminate 17 VAMCs, one in each pair.

- We excluded one VAMC without capacity data available in a small/medium metro area.

- We excluded one VAMC that lacked information on its complexity level.

This left 131 VAMCs for consideration from the initial list of 150. Based on the three attributes, we grouped the VAMCs as shown in Table 2-4.

Table 2-4. Capacity, Complexity, and Metropolitan Context of VAMCs Used in Selecting Interviewees

Complexity	Rural, Small-Capacity	Small/ Medium Metro, Small-Capacity	Small/ Medium Metro, Medium-Capacity	Small/ Medium Metro, Large-Capacity	Large Metro, Small-Capacity	Large Metro, Medium-Capacity	Large Metro, Large-Capacity
Complex (1a–1c)	0	8	24	22	2	8	11
Less Complex (2–3)	20	23	9	0	4	0	0

---

[4] VA reclassified its medical facilities in March 2015. Other analysis in this report used these later classifications, which increased the number of VAMCs to 166. See Section 3.3.1.

Complexity	Rural, Small-Capacity	Small/ Medium Metro, Small-Capacity	Small/ Medium Metro, Medium-Capacity	Small/ Medium Metro, Large-Capacity	Large Metro, Small-Capacity	Large Metro, Medium-Capacity	Large Metro, Large-Capacity
Total	20	31	33	22	6	9*	11

Source: Authors' analysis of 2012 Hospital Quality Report Card, Veterans Affairs Site Tracking system extract from September 30, 2014, and American Community Survey.
Notes: *One medium-sized VAMC in a large metro area was missing information on its complexity level. Blue-gray shading indicates groups from which VAMCs were selected for interviews.

We selected VAMCs from the groups shown above. The goal was to provide a distribution across the three categories of interest and to avoid smaller cells that include atypical VAMCs. Given the distribution of size and complexity across urbanization levels, we selected one VAMC from each of the following groups (shaded in Table 2-4):

- Rural, small, less complex
- Small-medium metro, small, less complex
- Small-medium metro, medium, complex
- Small-medium metro, large, complex
- Large metro, medium, complex
- Large metro, large, complex.

Of the 131 VAMCs, we eliminated 23 because they were not in the selected categories, and, to minimize the response burden on facilities, another 29 because they had already been selected for site visits by another Veterans Choice Act Assessment.[5] Due to overlap in these two categories, there were 84 VAMCs remaining to select from.

The final sample included two VAMCs per facility size category and a distribution across urbanization that is roughly proportionate to the distribution of facilities. We made the selection to account for geographic diversity. We also created ratios based on the 2012 report card of primary to specialty visits, and inpatient to outpatient visits, and we aimed for diversity in this regard as well.

We also contacted interviewees at the VISN level. We selected the VISN associated with each VAMC for interviews, unless the VISN was the subject of a site visit by another Veterans Choice Act Assessment (three VISNs). In those cases, the three remaining VISNs that were not subjects of site visits or interviews were substituted.

Finally, we selected one CBOC associated with each VAMC. When possible, we used the

---

[5] The number of VAMC site visits was later increased to 38, but this did not affect our selection.

Veterans Affairs Site Tracking data to identify those characterized as multispecialty CBOCs.

2.4.2   Protocol Development

We developed interview protocols that featured defined questions and then used elicitation techniques to provide respondents with space to offer rich answers and make connections on their own. These protocols allowed the team to focus the interviews on specific topics that matched the project goals without overly constraining and shaping respondents' answers.

Protocols were iteratively reviewed to ensure that the research questions were being covered. One to four question sets were targeted to each respondent group. Each protocol included an introduction describing the purpose and ground rules for the interview and covering verbal consent and confidentiality.

All RAND research that involves the acquisition of private, individual-level data are required to follow the common federal rule for the protection of human subjects. These guidelines are described in 45 Code of Federal Regulations 46 and in RAND's Multiple Project Assurance of Compliance (on file with the Department of Health and Human Services). The qualitative interviews underwent review by the Human Subjects Protection Committee, RAND's Internal Review Board. Our Internal Review Board submission included protocols, consent language, a recruitment email script, and a data safeguarding plan.

2.4.3   Interviews

For the expert interviews, we targeted 48 respondents and completed interviews with 38 respondents, representing a response rate of 79 percent. If the respondent consented, the interview was audio recorded and then professionally transcribed for analysis.

For the facility interviews, we targeted 88 respondents overall across the six VAMCs, six VISNs, and six CBOCs. Overall, we were able to identify individuals for the vast majority of respondent groups. We completed interviews with 61 respondents, representing a response rate of 69 percent. All facility interviews were conducted via telephone, usually with multiple interviewers or an interviewer and a note taker. If the respondent consented, the interview was audio-recorded and then professionally transcribed for analysis.

2.4.4   Analysis

Analysis was conducted using Dedoose, a commercial mixed-method, web-based data analysis platform. All interview transcripts were uploaded into Dedoose for thematic analysis. To identify and connect themes from across the interview data, we developed a coding structure for each domain. Domain-specific coding teams developed the coding structure based on the interview protocols and then dual-coded interview transcripts to establish coding reliability for that domain. The coding teams continued to develop codes and refine the coding structure as content was analyzed. Each domain coding team independently coded all transcripts with questions relevant to that domain. The overall code structure was continually revised through dialog within the qualitative team, particularly the team experts in the domain in question.

2.5   2015 Survey of VA Resources and Capabilities

The 2015 Survey of VA Resources and Capabilities was designed to identify clinically meaningful delays in care for the seven illustrative clinical populations chosen for Assessment B, and for primary care more generally. When survey respondents identified a delay in care, they were asked about the reasons for the delay and their proposed solutions. The survey was also designed to identify difficulties VA may be facing in recruiting, hiring, and retaining the clinical personnel necessary to provide care to Veterans in these populations.

The survey sample frame was all of VA's 141 administrative parents (local health care systems with at least one hospital and its affiliate clinics). The administrative parent within VA is defined as

> a collection of all the points of service that a leadership group (Medical Facility Director, Deputy Medical Facility Director, Chief of Staff, Associate or Assistant Director, and Nurse Executive) manages. The points of service can include any institution where health care is delivered. All of the data that originate from these points of service roll up to a single station number representing the administrative parent for management and programmatic activities.

The invitation to participate in the survey was sent via email directly to the Chief of Staff of the administrative parent. The email included instructions, links to the survey modules, and a signed letter from Dr. Carolyn Clancy, VA Interim Under Secretary for Health, encouraging VA employees to assist the Veterans Choice Act assessments. The survey was a web-based survey with eight modules allowing each module to be completed independently. The Chief of Staff was responsible for completing the Chief of Staff module, identifying the most appropriate individual to complete each of the clinical condition modules, and overseeing the completion and return of all survey modules. The survey was in the field for approximately two and a half weeks from Thursday, May 7, 2015, through Tuesday, May 26, 2015.

Detailed survey methods and results are provided in Appendix B.

2.6   Data Sources and Measures

In addition to data collected through the literature reviews, interviews, and survey, Assessment B drew upon various other data sources and measures, as described briefly in this subsection. Information about the analyses conducted using these and other data are found in Subsection 2.7.

2.6.1   Resources and Capabilities

Data sources and the concepts that we measured to assess current resources and capabilities across domains are described in Table 2-5.

Table 2-5. Data Sources and Measures for Assessing Resources and Capabilities (Other Than Literature Review, Interviews, Survey)

Resource Area	Data Sources	Concepts Measured
Fiscal	- Fiscal Year (FY) 2016 VA Budget Request - FY 2014 Veterans Equitable Resource Allocation Handbook	- Congressional appropriation - Allocation of funds to VISNs
Workforce and human resources	- Staffing and productivity data provided by Assessment G. including data collected from: - VISTA New Person File - VISTA Patient Care Encounter File - Monthly Program Cost Report - SK&A Office-Based Physician, Nurse Practitioner, and Physician Assistant Database - VA Planning Systems Support Group Enrollee file - VHA Support Service Center (VSSC) [See Strategic Analytics for Improvement and Learning Cube] - Medical Group Management Association Academic Survey - Medical Group Management Association Physician Compensation and Production Survey from Assessment G	- Supply of physician labor, by specialty - Supply of associate providers - Supply of therapists - Productivity - Location of non-VA providers - Timeliness of care

Resource Area	Data Sources	Concepts Measured
Physical infrastructure	▪ Veterans Affairs Site Tracking System ▪ American Community Survey ▪ American Hospital Association 2014 Annual Survey of Hospitals ▪ VA Planning Systems Support Group Enrollee file ▪ VHA Daily Bed Report, FY 2015 ▪ VA Veterans Transportation Program, 2015 ▪ HUD VASH Utilization Report ▪ HUD 2014 Raw Housing Inventory Count ▪ VA Surveys (Complementary and Alternative Medicine, Cardiovascular Specialty Care Services, Emergency Departments, Pain Management, Physical Therapy, Prosthetics and Sensory Aids Service, Recovery Oriented Mental Health Care, Surgical Services) ▪ VA Clinical Inventory Facility Profile Report ▪ VA Clinical Inventory Facility Services Report	▪ Number and distribution of VA facilities ▪ Complexity of VA facilities ▪ Availability of specific services and technologies related to illustrative clinical populations ▪ Geographic access to VA facilities
Interorganizational relationships	▪ VA/DoD Medical Sharing Office ▪ Fee Basis Claims System extract from Assessment I ▪ VA Central Fee Payment extract from Assessment C ▪ VA Budget Requests 2012-2015	▪ Amount and types of care purchased from DoD ▪ Purchased care spending, utilization, and distribution

Resource Area	Data Sources	Concepts Measured
IT	▪ VSSC	▪ Access to IT capability ▪ Use of the capability ▪ Usability and user satisfaction

2.6.2   Access

We used a number of data sources to assess the five dimensions of access described in Section 1, Introduction (see Table 1-2): geographic, timely, financial, digital, and cultural. To identify performance measures, we conducted an environmental scan of access measures in VA performance measure reporting systems and publications, including the Strategic Analytics for Improvement and Learning Value Model (VA, 2014h), VA Hospital Compare ASPIRE (VA, 2014d), Linking Knowledge & Systems (VA, 2014c), the VA Facility Quality and Safety Report (VA, 2013d), and other published reports. Measures include system-level measures, such as the percentage of new patients who complete a primary care visit within 30 days of their preferred date, and patient-reported measures, such as the percentage of patients reporting that, in the past 12 months when they called for an appointment for care needed right away, they were always able to get an appointment as soon as needed. In addition, the team analyzed 2010–2014 data from the VHA Survey of Veteran Enrollees' Health and Reliance upon VA (Survey of Enrollees). The Survey of Enrollees is an annual survey of more than 40,000 enrolled Veterans designed to collect information on Veterans not available from other sources for the VA Enrollee Health Care Projection Model. Analyses of the Survey of Enrollees allow for assessment of Veterans' attitudes regarding each of the dimensions of access, such as the degree to which VA providers treat patients with respect (cultural access) and the degree to which VA offers Veterans the best value for their health care dollar (financial access).

Table 2-6 shows the data sources and access concepts that we measured. A full list of access measures by domain is found in Appendix A, Table A-3.

Table 2-6. Data Sources and Measures of Access

Access Domain	Data Sources	Concepts Measured
Geographic	▪ VA Survey of Enrollees ▪ Veterans Affairs Site Tracking System ▪ American Community Survey ▪ Esri v10.2 Business Analyst Extension ▪ VA Planning Systems Support Group Enrollee file ▪ VA Clinical Inventory Facility Profile Report ▪ VA Clinical Inventory Facility Services Report ▪ SK&A Office-Based Physician, Nurse Practitioner, and Physician Assistant Database	▪ Ease of getting to VA facilities ▪ Travel distance ▪ Travel time ▪ Accessible by public transit ▪ Veterans' perspectives regarding ease of getting to VA facilities ▪ Proximity to non-VA providers
Timely	▪ VSSC ▪ VA Survey of Healthcare Experiences of Patients Patient-Centered Medical Home (SHEP PCMH) Survey ▪ VA Survey of Enrollees	▪ Timeliness of care for VA primary care, specialty care, and mental health care appointments ▪ Wait times for appointments ▪ Veterans' perspectives regarding timeliness of care, appointments and information
Financial	▪ Medical Expenditure Panel Survey ▪ VA Survey of Enrollees	▪ Cost of VA care ▪ Out-of-pocket expenses ▪ Lost work time ▪ Veterans' perspectives regarding the value of VA care
Digital	▪ VA Survey of Enrollees	▪ Veterans' Internet access
Cultural	▪ VA Survey of Enrollees	▪ Veterans' perspectives regarding the degree to which VA personnel treat them with respect
Cross-Cutting	▪ Yelp reviews of VA facilities	▪ Veterans' comments regarding experiences visiting VA facilities

2.6.3   Quality

We selected a subset of measures for analysis from the more than 500 measures of quality available in the VA system. We prioritized quality measures that reflect national standards and are reported by national performance measurement programs, as follows:

- Measures in the Healthcare Effectiveness Data and Information Set (HEDIS) developed by the National Committee for Quality Assurance (National Committee for Quality Assurance, 2014) for care in the outpatient setting.

- Measures of patient experiences with health care received in the outpatient and inpatient settings from the SHEP. SHEP surveys are adapted from the Consumer Assessment of Healthcare Providers and Systems (CAHPS) family of surveys (Agency for Healthcare Research and Quality [AHRQ], n.d.).

- ORYX measures (also known as the National Hospital Quality Measures) developed by the Joint Commission (Joint Commission, 2015) for care in the inpatient setting.

- Patient Safety Indicators developed by the AHRQ about adverse events and complications of care that may occur in the hospital (AHRQ, 2015).

- Thirty-day risk-standardized mortality and readmission measures developed by the Centers for Medicare & Medicaid Services (CMS) in conjunction with the Hospital Quality Alliance (CMS, 2014) for the inpatient setting.

Table 2-7 contains the data sources and concepts we measured to assess quality. A full list of quality measures can be found in Appendix A.

Table 2-7. Data Sources and Measures of Quality

	Data Sources	**Concepts Measured**
Safety	▪ AHRQ Patient Safety Indicators (data from VA and CMS Hospital Compare for non-VA hospitals) ▪ CMS Hospital Compare (data for VA and non-VA facilities) ○ Outcome measures	**Patient safety** ▪ Adverse events and complications ▪ Inpatient outcomes ▪ Readmission and mortality

	Data Sources	**Concepts Measured**
Effectiveness	**Outpatient** • HEDIS Outpatient Quality Measures (data from VA and National Committee for Quality Assurance reports for non-VA) **Inpatient** • CMS Hospital Compare (data for VA and non-VA facilities) ○ ORYX measures	**Outpatient** • Screening, prevention, and wellness • Chronic condition management • Comprehensive diabetes care • Cholesterol management for patients with cardiovascular conditions • Antidepressant medication management **Inpatient** • Care processes for selected conditions (for example, acute myocardial infarction, pneumonia, heart failure, and surgical care)
Patient-centeredness	• VA SHEP PCMH (data from VA for outpatient experiences; no nationally representative non-VA data) • VA inpatient SHEP (data from VA for inpatient experiences) • CAHPS Hospital Survey (data from CMS Hospital COMPARE for non-VA hospitals)	**Veterans' reports of outpatient care experiences** • Communication with health care providers • Self-management support • Comprehensiveness of care • Helpful, courteous and respectful office staff **Veterans' reports of inpatient care experiences** • Communication with nurses and doctors • Responsiveness of hospital staff • Hospital environment • Care transition

Note: Performance measure data did not allow for assessment of Institute of Medicine quality domains of timeliness, efficiency, or equity.

2.7 Data Analyses

Using the quantitative and qualitative data sources described in the previous subsections, we conducted analyses to assess VA's current resources and capabilities, the level and nature of access to VA care, barriers and facilitators to access, and, where possible, how VA compares with external benchmarks. We looked for and considered external benchmarks for each measure that we assessed. Cases in which we do not report a benchmark reflect one of three possible reasons. In some cases no external benchmark was found. In the others a benchmark was found, but the comparison was deemed invalid due to differences in the patient population

(for example, demographics, health needs, reliance on VHA) or in the way that care is delivered. The third possibility is that the benchmark comparisons were being carried out by another assessment (for example, Assessment G compares VHA physician labor supply and productivity to external benchmarks) and are reported elsewhere.

In this subsection, we briefly highlight the methods used in the analyses of VA Resources and Capabilities (Subsection 2.7.1), Access to VA Care (Subsection 2.7.2) and Quality of VA Care (Subsection 2.7.3).

2.7.1   VA Resources and Capabilities

2.7.1.1   Fiscal Resources

Our primary method for assessing fiscal resources was a targeted review of the literature, with a particular focus on VA documents related to the budgeting and allocation process (see Subsection 2.3). The literature review was complemented by several descriptive quantitative analyses detailing the expenditures on Veterans over time, using publicly available data from catalog.data.gov. We collected qualitative information from facility leadership regarding problems with the allocation models and flexibility with funding. We conducted interviews with congressional experts on VA to understand how congressional priorities impact VA's overall allocation (see Subsection 2.4).

2.7.1.2   Workforce

We used a number of measures to assess VA's health care workforce resources and capabilities. We developed descriptive data tables describing total workforce and productivity estimates for physicians, associate providers (for example, nurse practitioners, physician assistants, social workers, clinical nurse specialists), and therapists (for example, physical, speech, and occupational therapists). We generated reports for representative specialties, including those relevant for the illustrative clinical populations, that contain summary data at the facility level on physician workforce capacity and productivity within a given specialty. We also used wait-time data in combination with specialty-specific productivity estimates to identify facility-specialty combinations that may be particularly prone to capacity constraints.

We interviewed VA employees and others with VA expertise to gather information related to resources, capabilities, access, and quality. In particular, we asked about any provider number and productivity issues that may be causing capacity constraints at their facility. We supplemented these analyses with an extensive review of the literature (see Subsection 2.3).

VA providers. We measured the supply of the *specialty workforce* using full-time equivalent (FTE) counts for physicians, associate providers, and therapists. We used various FTE measures. For overall measures of FTE counts, we used "worked" FTEs, which does not include non-work-related paid time such as paid leave. For all other FTE measures, we used "clinical" FTEs which is a subset of worked FTEs calculating after removing non-clinical activities such as administration and research. We measured specialty physician and associate provider productivity using relative value units (RVUs), a commonly used method of counting health care output that weights each health care service for the time and other resources needed to

provide it. Because of the way RVUs are constructed, they are best used for comparisons within rather than across specialties. For therapists, we measured productivity in terms of the number of encounters per therapist clinical FTE. For *primary care*, we measured productivity of physicians by measuring "panel size" of primary care physicians, which we defined as the number of unique patients (by social security number) seen by each primary care physician per year. We also assessed variation in specialty care workforce supply and productivity and the extent to which various factors might affect workforce supply through changes in the recruitment and retention of various provider types. We also combined wait-time and productivity data to assess the source of potential capacity constraints (that is, insufficient FTE or productivity). For each of the seven illustrative clinical populations, we selected a subset of specialties that care for patients within the population and characterized facilities based on a measure of accessibility (measure of wait times for new patients) and productivity (RVU estimates). We used the wait-time variables to categorize each facility-specialty combination as having high or low wait times and described the distribution of these capacity constraints across facility-specialty combinations. We then used the findings from the literature reviews and interviews to identify specialties for which there are likely capacity constraints as well as potential causes of capacity constraints.

2.7.1.3 Physical Infrastructure

We identified and geocoded the locations of all VA health care sites: hospitals, VAMCs, health care centers, multispecialty CBOCs, primary care CBOCs, other outpatient services sites, extended care sites, and domiciliary residential care treatment programs. We also identified and geocoded the locations of Transportation Services and Veteran Housing Services.

We reported enrollee-adjusted size estimates (average daily number of patients per 10,000 enrollees) for each medical facility, aggregated at the VISN level. We also examined the number and distribution of sites by their complexity level. Each site has a range of capabilities. We identified and defined clinical care services that are definitive for one or more of the seven illustrative clinical populations described in Table 2-1. Table 2-8 lists an example of such services for TBI. A full list of 27 services and their definitions is provided in Appendix A (see Table A-2). To provide more detail about resources available for specific conditions, we report the number and distribution of sites that offer the services needed for the selected clinical populations.

Table 2-8. Example of Condition-Specific Services for Traumatic Brain Injury

Services	Definition
Polytrauma Support Clinic Team	An interdisciplinary team of health care providers who provide and coordinate rehabilitation services for patients with traumatically induced structural injury and/or physiological disruption of brain function as a result of an external force. Polytrauma support clinic teams also conduct comprehensive evaluations of patients with positive TBI screens, and develop and implement rehabilitation and community reintegration plans.
Polytrauma Network Site	Site that provides inpatient and outpatient rehabilitation care and coordinate polytrauma and TBI services throughout the VISN, generally with less comprehensive services than Polytrauma Rehabilitation Centers. (VA-specific term)
Polytrauma Rehabilitation Center (Program)	Regional referral center for the comprehensive acute rehabilitation for Veterans with complex and severe polytrauma. Polytrauma rehabilitation centers maintain a full staff of dedicated rehabilitation professionals and consultants from other medical specialties to address the complex medical and psychosocial needs of patients with polytrauma. These centers serve as a resource for educational programs and best practice models for other facilities across the polytrauma support clinic. (VA-specific term)
TBI Specialty Care	Specialty services designed for evaluation and treatment for patients with TBI.

Sources: All definitions, except for TBI, adapted from the VHA Handbook 1172.01, March 20, 2013. Definition for TBI provided by RAND experts.

To examine how VA facility locations, size, complexity, and service offerings may be related to delays in care, we interviewed 29 medical facility staff[6] and Veteran advocates about their experiences in the system. Interviewees were asked to describe how physical infrastructure is used in patient care. We asked about physical space, medical equipment and supplies, diagnostic capabilities, exam rooms, and inpatient facilities. We discussed the extent to which these parts of VA infrastructure are undersupplied, adequate, or oversupplied. Interviewees

---

[6] Interviewed staff included facility associate directors, chief medical officers, clinicians, and administrators.

were also asked to comment on strategies that could address under- or oversupply of physical infrastructure.

2.7.1.4 Interorganizational Relationships

We used several measures to describe the extent of care provided through relations with non-VA entities. Measures of utilization included non-VA outpatient visits, mental health outpatient visits, and patients treated in non-VA inpatient settings compared with VA facility utilization. We also measured total VA spending on various categories of purchased care as well as care purchased from VA partners such as DoD and the Indian Health Service.

We performed a targeted literature search to obtain information on VA purchased care. In addition, the team reviewed qualitative information gathered from interviews conducted by Assessments B, C, and I, and responses to questions contained in the 2015 Survey of VA Resources and Capabilities regarding the use of non-VA medical care. This information provided additional context and detail regarding the various types of VA purchased care and the challenges associated with accessing, utilizing, coordinating, and reimbursing care.

2.7.1.5 IT

We conducted a review of the academic and gray literatures to identify the full range of IT resources and capabilities in use at VA and any evaluations of their impact on timely and accessible care. We selected six capabilities as most relevant to Assessment B. Three of these are emerging modes of access: (1) telehealth (clinical video in particular), (2) patient portal (MyHealtheVet), and (3) mobile applications (limited to those that facilitate Veteran communication with VA). Two capabilities are hypothesized to be relevant to timely and accessible care via their relationship to efficiency of VA providers: (4) data exchange (including within VA, VA-DoD, and VA–private sector) and (5) core electronic health record functionalities (with a specific focus on the impact of usability). We also identified one capability (or class of capabilities) that we hypothesized is relevant to timely and accessible care by prevention, addressing the "demand" side of care: (6) care management (home monitoring in particular). We collected a variety of measures related to these capabilities.

We used interviews with stakeholders internal and external to VA to address the mechanisms by which the capability may affect timely and accessible care to Veterans, VA's resources and capabilities to use the capability, and barriers to expanding use of and improvements to the capability. We led or participated in three different types of qualitative data collection efforts. First, we recruited for and conducted our own interviews with stakeholders inside and outside of VA. Second, we participated in facility-level interviews led and coordinated by the qualitative team. Third, we participated in interviews led and coordinated by Assessment H.

2.7.2 Access to VA Care

2.7.2.1 Geographic Access

We built a geographic information system (GIS) that would facilitate geographical analyses of VA resources and enrollees in 2013–2014, extending methods used in previous studies of

access to health care (Branas et al., 2005; Nallamothu et al., 2006; Klein et al., 2009; Culpepper et al., 2010; Concannon, Nelson, Goetz, & Griffith, 2012; Concannon, Nelson, Kent, and Griffith, 2013). A GIS links data by place and facilitates analyses that account for joint distributions of geographic, facility, population, and other data. Data are organized in a GIS by *layer group,* a capability that readily enables analysis in a variety of different geographic aggregations. The GIS was built in Esri's ArcGIS Version 10.2.

The primary outcome of the analysis is an estimate of the proportion of the enrollee population with access to VA and non-VA providers. Enrollees are Veterans who have signed up for the VA health care system.[7] We analyzed several different access standards, including a 40-mile straight line distance, 40-mile driving distance, 60-minute driving time, and 60-minute public transit time. All driving time analyses were adjusted in separate analyses for traffic slowdowns during rush hour travel in 101 metropolitan areas for which observed rush hour slowdowns are documented in the *2012 Urban Mobility Report* (Schrank, Eisele, & Lomax, 2012).

The team estimated the proportions of enrollees who have geographic access—according to each of these standards—to VA medical facilities with different levels of complexity and different capabilities. The VA system measures complexity of each administrative parent and its satellite VAMCs and CBOCs in six levels. The VA system also identifies specialized services and capabilities that are available to treat individual clinical populations; we looked at access to 27 of these services. These analyses focused on access to physical infrastructure, such as beds and clinical care space, and access to diagnostic and interventional medical technology, such as catheterization labs and coronary artery bypass graft suites for patients with acute coronary syndromes. In all analyses, we assessed variation in geographic access estimates by VISN.

We also estimated geographic access to purchased care for enrollees living outside the 40-mile driving distance boundaries around VA medical facilities. This assessment focused first on access to non-VA hospitals at three levels of complexity (academic, teaching, and community hospitals). Next, we focused this assessment on access to non-VA clinicians practicing in 12 clinical specialties.

2.7.2.2   Timeliness

We analyzed system-level measures of timeliness, including wait times for primary care, mental health care, and specialty care appointments, as well as Veteran reports regarding access to timely care, appointments, and information from the SHEP PCMH survey. We assessed timeliness of care in VA overall and compared across VA facilities. Nationally representative data for non-VA settings are not available for these measures. Therefore, we provide context for VA performance on these measures by presenting data on non-VA performance from the literature (for measures of wait time) and a public database (for SHEP measures).

---

[7] Not all enrollees have actually received VA health care, but we use enrollees as our primary means of distinguishing that group of Veterans who are eligible to access VA health care.

For each measure, we conducted descriptive analyses of the performance rates available at the facility level, noting the variation in performance across facilities nationwide. We summarized the distribution of each measure using the mean, minimum, maximum. Means reported in Section 4 were calculated as a simple unweighted mean of the facility-level means. A VA benchmark was calculated as the mean of the top 10 percent of VAMCs based on performance for each measure. This benchmark reflects the rate of performance on a given measure that has been shown to be achievable at 14 VA facilities. For measures related to wait times in the first half of FY 2015, we classified the performance of each facility into one of three categories relative to the benchmark: "near the benchmark" (within 0.5 standard deviation [SD] above or below the benchmark), "below the benchmark" (0.5 to 2.0 SD below the benchmark), or "far below the benchmark" (>2.0 SD below the benchmark).

The statistical significance of the difference between each pair of means for VA and non-VA facilities was tested using a t-test. We tested for statistically significant differences in SHEP PCMH scores on selected measures between VA hospitals grouped by their performance on wait times for primary care, specialty care, and mental health care, using t-tests for pairwise comparisons with Bonferroni adjustment for multiple comparisons.

For measures with rates available for more than one year, we created a descriptive time series and classified changes over time as improving, worsening, or remaining the same, using the Cohen's d statistic as a measure of effect size to determine whether an improvement is large enough to be of interest after accounting for variability in the data. Cohen's d is calculated by dividing the change over time in measure rates by the standard deviation of the rates in the earliest time period. As variability of a measure rate decreases relative to the magnitude of the change in measure rates over time, the magnitude of Cohen's d increases, indicating a larger effect. According to Cohen (1988), no specific value or cutpoint indicates when an effect is significant or meaningful; however, he suggested three categories of effect magnitude: "small, $0.2 \leq d < 0.5$," "medium, $0.5 \leq d < 0.8$," and "large, $d \geq 0.8$."

We analyzed data from the Survey of Enrollees regarding Veterans' attitudes related to each of the dimensions of access, and analyzed online reviews of VA facilities to assess the relative frequency of comments related to access in each dimension.

The team analyzed five years of data (2010–2014) from the Survey of Enrollees to describe attitudes of Veterans related to access to VA care. We assessed the proportion of Veterans completely agreeing or agreeing with each question relevant to access over time, and by Veteran characteristics, including age, sex, race/ethnicity, income, employment status, insurance status, self-reported health, and priority group. To determine the degree to which observed changes over time were due to changes in the sociodemographic composition of Veterans, we also conducted multivariate logistic regressions predicting each question of

interest. Models included independent variables for all the Veteran characteristics noted above, as well as an indicator variable for each year.[8]

In addition, we analyzed narrative reviews of VA facilities submitted by users of the online rating website Yelp. Yelp reviews are posted voluntarily, and therefore may not be representative of the full population of Veterans; however, the reviews are useful for gaining perspectives from Veterans regarding barriers and facilitators to access to care at VA facilities. We identified VA facilities by their telephone numbers, combined duplicate Yelp entries for the same facility, and excluded reviews for nonmedical services offered by the facilities (for example, canteens or cafeterias). With permission from Yelp, we collected from the website full-text reviews posted between July 2007 and March 2015. One researcher read a subset of the reviews to identify thematic categories that reflect a concept or theme that could be present or absent in any particular review. We paid particular attention to the dimensions of access identified in the Assessment B conceptual model.

2.7.3   Quality of VA Care

We compared quality measures across VA facilities where available using the same methods used in analysis of timely access measures (Subsection 2.7.2.2). For each quality measure, we conducted descriptive analyses of the performance rates available at the facility level, noting the variation in performance across facilities nationwide. We summarized the distribution of each measure using the mean, minimum, and maximum. The performance rates for the quality measures reported in Section 5 and Appendix G tables were calculated as unweighted means of the facility-level means.[9] A VA benchmark was calculated as the mean of the top 10 percent of VAMCs based on performance for each measure. The statistical significance of the difference between each pair of means for VA and non-VA facilities was tested using a t-test.

For HEDIS quality measures for outpatient care, we compared VA performance rates with those for commercial, Medicaid, and Medicare health plans, as reported by the National Committee for Quality Assurance State of Health Care Quality Report (National Committee for Quality Assurance, 2015). The measures used by VA and the National Committee for Quality Assurance differ in some important ways (see Appendix A for details).

For ORYX quality measures for inpatient care (The Joint Commission, 2015), we compared VA performance rates between VA and non-VA hospitals as reported on the CMS Hospital Compare website. For other inpatient measures, we compared VA performance rates provided by VA (some measures) and on CMS Hospital Compare (other measures) with data for non-VA

---

[8] The Survey of Enrollees data collection modes changed in 2012. Our multivariate modeling did not explicitly account for this, but the trends we report are consistent in the time periods before and after 2012, suggesting that reported changes over time reflect true differences in Veterans' responses.

[9] The value of mean measure rates calculated for this report may differ slightly from means reported in VA publications for the same time period, due to differences in methods used to calculate the means. For this report, we calculated an unweighted mean of facility-level means, whereas VA calculates a national mean value for each performance measure based on patient-level data.

---

hospitals on CMS Hospital Compare. To ensure optimum comparability between VA and non-VA facilities in our analysis, we identified a subset of non-VA facilities with similar characteristics using data from the American Hospital Association (American Hospital Association, 2014). This dataset includes facility-level characteristics for 135 VA facilities and 6,332 non-VA facilities.[10] We analyzed measures for this report for which there were data available both for VA patients and the non-VA comparison groups. The full set of quality measures used in this assessment is shown in Appendix A, Subsection A.5.

To identify non-VA hospitals most similar to VA facilities, we conducted propensity score matching based on the predicted likelihood that a non-VA facility could be a VA facility given certain characteristics (covariates). Our approach for identifying matched non-VA facilities is described in Appendix A, Subsection A.5.2. For matching, we selected four facility characteristics most likely to differ between VA and non-VA hospitals, and shown to be predictive of performance on Hospital Compare measures (Lehrman et al., 2010): bed size (<100 beds, 100-199 beds, and 200+ beds), Census division (East North Central, East South Central, Mid-Atlantic, Mountain, New England, Other, Pacific, South Atlantic, West North Central, and West South Central), location (urban, rural),[11] and teaching status (teaching facility, nonteaching facility).[12] Three non-VA facilities were matched to each VA facility. After conducting propensity score matching, there were no significant differences between VA and the matched non-VA facilities for any characteristic in the model, indicating that the two sets of facilities were well matched. In estimating the results for VA and non-VA comparison groups, if a VA hospital had a missing value for a measure, the non-VA hospitals matched to that hospital were excluded from the analysis of that measure. In addition, if one of the matched non-VA hospitals had a missing value for a measure, the remaining two non-VA hospitals were "up-weighted" by a factor of 3/2 or 1.5, and if two of the matched non-VA hospitals had a missing value for a measure, the remaining hospital was "up-weighted" by a factor of 3. Results are presented for comparisons of VA facilities and non-VA hospitals overall. Appendix A, Subsection A.5.2 provides additional detail regarding the propensity score matching methods.

---

[10] Seven of 135 VA facilities in the American Hospital Association could not be matched to the CMS Hospital Compare file, and were therefore not included in the analysis of CMS Hospital Compare measures (see Appendix A, Subsection A.5.2 for more detail).

[11] Facilities are categorized as urban or rural based on the American Hospital Association definition: "A rural hospital is located outside a Metropolitan Statistical Area (MSA), as designated by the U.S. Office of Management and Budget (OMB), effective June 6, 2003. Urban hospitals are inside Metropolitan Statistical Areas."

[12] Teaching facilities are defined to include major and minor teaching hospitals, with a major teaching hospital having a Council of Teaching Hospitals designation and a minor teaching hospital having another teaching hospital designation. Facilities without a teaching hospital designation were classified as nonteaching facilities.

2.8   Policy Analysis

2.8.1   Developing Policy Options

To identify and evaluate potential policy options for improving VA's ability to provide timely and accessible care to Veterans, we used a multipronged analytic approach combining data from a systematic literature review, key informant interviews, and quantitative analyses projecting the impact of various policy scenarios on access, with ongoing input and guidance from a panel of in-house advisors with expertise in VA health care delivery research and operations.

First, in consultation with our in-house advisory panel, we established a framework of potential policy options based on 1) their primary objective to enhance timely access to care either within VA or outside VA and 2) the approach to achieving the stated objective, either by modifying the amount and/or type of resources utilized or by increasing the productivity of existing resources.

Second, we established the criteria for evaluating policy options. We began with a standard set of evaluation criteria, which we refined for saliency to current VA context through an iterative process using data from key informant interviews, a systematic literature review, and input from our advisory panel. Our final set of evaluative criteria included impact on access, fiscal impact, stakeholder acceptability, and operational feasibility. Additional information about how we refined our evaluation criteria is found in Appendix A (see Subsection A-6.1).

Third, we identified a set of potential policy options for improving VA's ability to provide timely and accessible care to Veterans through the systematic literature review. The literature review approach is described above in Table 2-3 and in Appendix A (see Subsection A.6.2). We used this initial set of options as a starting point for developing a final list of policy options and iteratively added, removed, and modified options as further information was collected through the key informant interviews and advisory panel guidance.

Finally, we applied the evaluation criteria to each of the final policy options. We excluded from our final list policy options that (1) were infrequently raised during interviews, or (2) were expected to face significant challenges with respect to at least two of the evaluation criteria. We used the evaluation criteria to compare and contrast items on the final list of selected policy options in order to provide context for their viability as an approach to improving timely and accessible care in VA.

2.8.2   Projecting Future VA Resources and Capabilities

We projected the amount of health care services supplied under several scenarios and compared these figures to projected demand from VA's Enrollee Health Care Projection Model (EHCPM). The demand projections have some limitations (described in Section 6), but are used in VA planning. Assessment A projects how factors affecting demand, such as the size and composition of the Veteran population and their unique health care needs, will change over time, but does not provide estimates of the demand that VA will face. Still, the estimates from A provide useful context for interpreting and assessing the EHCPM demand estimates. The

results from Assessment A indicate that the number of VA patients is expected to rise slowly through FY 2019 and then begin to decrease. This is consistent with the increases in demand projected by the EHCPM through FY 2019. However, based on results from Assessment A, we expect to see decreases in demand after FY 2019.

In the first supply scenario, the projection accounts for changes in the number of VA providers based on historical trends but assumes no changes in productivity between FY 2014 and FY 2019. This projection indicates how the growth in VA provider supply would need to differ from historical growth rates to meet the demand EHCPM projects if there were no other changes that affect productivity. The second supply scenario projects the health care services supplied, accounting for changes in the productivity of existing resources, holding the provider supply constant between FY 2014 and FY 2019. This projection provides an estimate of the effect of productivity changes alone with no changes in the amount of resources. In the third supply scenario, we allow both the number of providers and their productivity to change.

Under supply scenario one, we forecasted the number of provider FTEs, given historical trends, for each specialty and administrative parent combination. We estimated a time series regression model using FTE data from the VA Productivity Cube for FY 2008 through FY 2014. We then compared the percentage growth in FTEs between FY 2014 and FY 2019 to the percentage growth in projected demand from the EHCPM over the same time period. If the difference in the growth rate is large, it is more likely that VA will have difficulty meeting projected demand under this scenario. For example, if, from FY 2014 to FY 2019, an administrative parent has a 10-percent increase in cardiology FTEs and a 15-percent increase in cardiology demand RVUs, the growth in projected demand would exceed the growth in projected supply and thus could point to a potential gap in the future.

For supply scenarios two and three, we estimated how much additional supply can be created through improved productivity (that is, RVU per FTE). For supply scenario two, we estimated how much additional supply can be achieved in FY 2019 over realized supply in FY 2014 if low-productivity providers increase their productivity (holding the number of FTEs constant). We created benchmarks that represent realistic productivity levels that could be achieved in VA system. To do this, we analyzed FY 2014 variation in services provided at each administrative parent in each specialty (measured as RVUs per provider FTE). We identified the 25th, 50th, and 75th percentiles of the distributions of productivity for each specialty. We then projected the effects of increasing productivity of existing resources at all administrative parents to at least the level of the 25th, 50th, and 75th percentile of the FY 2014 distribution for each specialty:

- **Productivity Level 1**: All administrative parents operate at least at the FY 2014 25th productivity percentile within each specialty nationally
- **Productivity Level 2:** All administrative parents operate at least at the FY 2014 50th productivity percentile within each specialty nationally
- **Productivity Level 3:** All administrative parents operate at least at the FY 2014 75th productivity percentile within each specialty nationally.

In scenario three, we projected the effect on supply of an increase in the productivity of low-productivity providers in combination with the forecasted change in FTEs.

We also analyzed several hypothetical policy options that explore how the projected demand for FY 2019 might be met through better matching demand RVUs to capacity FTEs without adding additional FTEs. These policy options involve either redistributing the demand geographically through a mechanism such as telehealth, or redistributing the supply through targeted layoffs and hiring or incentivizing current providers to relocate. To project this option, we assessed how many RVUs would be gained for each specialty if all administrative parents were performing at or above the current 25th, 50th, and 75th percentile of RVU/FTE for each specialty. We then compared this gain in RVUs to the projected increased demand of RVUs from FY 2014 to FY 2019 from the EHCPM. We calculated this change in RVUs as a percentage of the sum of the total FY 2014 RVUs and the proposed RVU gain. This percentage reflects the proportionate amount of care that would be redistributed to achieve the 75th percentile performance on RVUs/FTE across all administrative parents.

2.9   Section Conclusion

This section has provided a high-level discussion of the following methods used in Assessment B:

- **Illustrative clinical populations:** We selected seven illustrative clinical populations to provide a more detailed understanding of VA capabilities, resources, and accessibility in selected subpopulations of Veterans, and to supplement analyses of VA as a whole.

- **Literature reviews:** We conducted several literature reviews to provide background and context for the assessment. For each type of resource (for example, fiscal, physical infrastructure), we conducted a targeted literature review to identify information about current levels, trends over time, and key issues and concerns. We also conducted formal, in-depth systematic literature reviews to assess the evidence related to access, quality, and potential policy options for enhancing VA's resources and capabilities.

- **Interviews:** We conducted interviews with VA employees and others with VA expertise to address questions that could not be answered with sufficient detail by literature review or analysis of quantitative or survey data. Interviews spanned a number of topics and research questions related to VA resources, capabilities, access, and quality.

- **2015 Survey of VA Resources and Capabilities:** The 2015 Survey of VA Resources and Capabilities was designed to identify clinically meaningful delays in care for the seven illustrative clinical populations chosen for Assessment B, and for primary care more generally. The survey also sought to identify difficulties VA may be facing in recruiting, hiring, and retaining the clinical personnel necessary to provide care to Veterans in these populations.

- **Data sources and measures:** Assessment B drew upon numerous data sources and measures to assess current resources and capabilities across domains, to assess the five dimensions of access, and to analyze the quality of care available in the VA system.

- **Data analyses:** Using both quantitative and qualitative data sources, we conducted analyses to assess VA's current resources and capabilities, the level and nature of access

to VA care, barriers and facilitators to access, and, where possible, how VA compares with external benchmarks.

- **Assessing options for enhancing VA resources and capabilities:** We developed a method for projecting future resources to compare with forecasted changes in patient demand for VHA treatment to identify potential gaps. We used a multipronged approach to identify and analyze a reasonable range of feasible policy options to enhance VA's ability to provide timely and accessible care to Veterans.

In the following sections, we will show the results of the analyses we performed using these methods. Additional information about the methods can be found in Appendix A.

This page intentionally left blank.

3   Assessment of VA Resources and Capabilities

VA is a unique, extensive health care delivery system with a large number and variety of resources and capabilities at its disposal. VA's estimated FY 2015 budget for health care is about $60 billion, and the FY 2016 advanced request is $63 billion. VA includes 144 hospitals, approximately 700 outpatient clinics, more than 30,000 employed physicians, and more than 25,000 associate providers and therapists. VA is unique in both its scope and its roles. In terms of scope, no other U.S. health care system has a comparable geographic reach and diversity of health care resources.

Primary among VA's roles is direct health care service delivery to the more than 9 million Veterans enrolled for VA health care (2.8 percent of the U.S. population). However, VA does not provide care for all Veterans, or even all enrollees; 42 percent of Veterans are enrollees, and 64 percent of enrollees are users of VA health care. Among users, while some receive all of their health care from VA providers, others have coverage through health insurance such as Medicare, Medicaid, or private coverage. VA estimates that current VA users get, on average, about 21 percent of their total physical medicine visits from VA, 38 percent of their emergency room visits from VA, and 66 percent of their prescriptions from VA.

VHA operates several dozen specialty programs and "Centers of Excellence" largely focused on clinical topics of special importance to Veterans (e.g., the War Related Illness and Injury Study Center). While the organization and mandates vary by topic, both the programs and centers are generally based in VAMCs and offer patient care as well as conduct research and do outreach to both patients and health care providers. Many operate as "hub-and-spoke" systems with the centers serving as hubs and having relationships with other VA medical facilities. For example, there are 16 Epilepsy Centers of Excellence and several dozen other medical facilities that belong to the National VA Epilepsy Consortium.

VA also performs roles other than direct patient care that contribute to its unique position. These roles include health care training and graduate medical education, research, and national security emergency support.

In this section, we examine the resources and capabilities that VA currently has at its disposal to generate the supply of health care services available for Veterans. As described in Section 1, we categorize the resources and capabilities into five broad domains:

- Fiscal resources
- Workforce and human resources
- Physical infrastructure
- Interorganizational relationships
- IT.

For each domain, we describe the current level of resources and capabilities, as well as barriers to using them effectively. Where possible, we also describe variation in the level of resources and capabilities across VISNs and administrative parents. In a small number of cases, we are able to compare VA resources and capabilities against external benchmarks to provide a sense

of where VA stands relative to the private sector. In most cases, however, the differences between VA and other health care systems and the populations they serve make such comparisons difficult to interpret and thus of limited value.

3.1   Fiscal Resources

Fiscal resources are critical to VA's current and future ability to provide accessible, high-quality care. As described in Section 1, fiscal resources constitute the revenue stream or funding mechanisms for the organization. Meyer, Davis, and Mays (2012) describe a variety of measures for analyzing fiscal resources, including overall budget and sources of revenue, as well as expenditures such as per capita spending. A higher level of financial resource is not necessarily an indication of better performance on health outcome measures, since financial resources contribute to an organization's ability to acquire or develop other resources and capabilities such as hiring staff, funding programs, or acquiring physical infrastructure (Mays et al., 2009).

In this subsection, we examine VA's financial resources in two ways:

- Assess the budget development process and how it is affected by congressional priorities.
- Consider how funds are allocated to facilities and identify any problems with the allocation process as well as other constraints on the funding process that prevent facilities from using money effectively.

The first approach we use for assessing VA fiscal resources is to examine the VA budgeting process. As described below, there are indications that VA develops its medical services budget from older data and that there can be problems with the assumptions used in this process. Medical administration, facilities, and IT budgets are developed through separate processes.

We also consider how congressional priorities affect the VA budget. Congress appropriates VA's budget as a nondefense discretionary program; thus, congressional priorities can influence both the level of money available and the way VA chooses to spend the money once allocated. Funding for other large federal health programs differs in important ways from the VA health program. Medicare is considered an entitlement program; funding is provided from the Medicare Trust Fund, spending is mandatory, and the program's annual cost has no formal budget constraint. TRICARE funding is included in the DoD appropriation and is therefore discretionary, but the benefit is well defined, and DoD must cover any costs incurred beyond the appropriated funding. Congressional priorities can also direct money away from the overall budget for patient care toward specific programs through the special purpose funds. According to interviewees at VA medical facilities, these "silos" of money can make it difficult for facilities to efficiently make use of their entire budgets in any given year.

A second approach we use to assess VA's fiscal resources is to examine how VHA's own allocation process affects the level of resources available across regions. VHA's allocation process can cause difficulties for particular facilities because the allocation method also uses data from several years prior to the actual allocation year, although the allocation method is different from the method used to create the budget projections. Allocations for items such as facilities and IT can also affect the facility-level spending process. We also consider other

---

funding constraints identified by facility leaders that they believe limit their ability to use resources effectively.

In addition, we discuss whether we can use comparisons of the level of spending that results from the budgeting and allocation processes to private-sector spending to assess whether VA's total level of financial resource is adequate. While in theory such comparisons would be useful, as will be discussed below, in practice the differences in the patient population and the way care is delivered between VA and the private sector make comparisons of per capita spending difficult to interpret and thus of limited value.

A summary of the methods used in these analyses is shown in the box.

Overview of Methods and Data for Assessment of Fiscal Resources

- To assess VA's budget process, we conducted a targeted literature review of VA documents, government reports, peer-reviewed literature, and recent congressional testimony. Data sources included the FY 2016 VA Budget Request and FY 2014 Veterans Equitable Resource Allocation Handbook.
- The literature review was complemented by several descriptive quantitative analyses detailing the expenditures on Veterans over time, using publicly available data from catalog.data.gov.
- We also interviewed VA leadership in the VA Central Office and in facilities for their perspectives on the budget and allocation processes.
- For complete details of the methods used to assess fiscal resources, please refer to Section 2 of this report.

3.1.1 VA Budget for Health Care

VA is funded through annual congressional appropriations. Most VA funds are budgeted through *advance appropriations*, which are typically designated one or more years in advance of the time the funds become available. The intent of advance appropriations is to give VA additional time to plan spending. *Regular appropriations* act as supplements to fund unexpected needs that arise (Panangala, 2014).

As with other federal departments, budget planning for VA starts roughly 18 months before the appropriation decision by Congress. The agency develops a budget request using the EHCPM, described in greater detail below. The budget is then sent to the Office of Management and Budget for review, and then submitted to Congress as part of the President's budget in January, nine months before the beginning of the fiscal year. Congress holds budget hearings during the spring months and develops an appropriations bill giving federal agencies the authority to spend the specified funds. In recent years, passage of the appropriation bill containing VA health care funding has generally been delayed, necessitating a continuing resolution that freezes spending at the prior year level and precludes spending on new programs.

VA's budget for the variable costs of outpatient and inpatient care is formulated using the EHCPM, which projects the estimated demand and cost for services. The budget includes funding for medical staff, supplies, and equipment. EHCPM was first introduced in 1998 to

---

support the forecasting of Veteran health care enrollment as mandated by the Veteran's Health Care Eligibility Reform Act of 1996 (Congress, 1996). For FY 2016, the model projects about 90 percent of the health care budget (VA, 2015a). The remaining 10 percent consists of several categories of services that are modeled separately from the EHCPM. For example, capital planning and some IT services are planned centrally for VA through a separate process. There are several additional programs not budgeted through the EHCPM, including the Civilian Health and Medical Program Veterans Administration, which provides care to widows, spouses, and dependents of some Veterans, and purchased care, which allows Veterans to use private providers under some circumstances (Panangala, 2014).

Congress approves the overall VA budget, adjusting it up or down. In an unusual step, Congress, in passing the Veterans Choice Act in 2014, provided additional funds through an appropriation to be spent over three years on purchased care for certain Veterans unable to get care in VA facilities. During the typical appropriations process, members of Congress can influence VA priorities by highlighting the need for specific medical services or programs during budget hearings. After VA proposes a budget based on its projected needs, Congress approves the budget or a modified version of it, VA then allocates the money to the VISNs and the VISNs further allocate funding to facilities (discussed in Subsection 3.1.2).

3.1.1.1 Budget Process

As noted above, the EHCPM is VA's main budgeting tool and is used to project the demand for medical services. The EHCPM consists of three submodels: the Enrollment Projection Model, the Utilization Projection Model, and the Unit Cost Projection Model, all of which we describe below (GAO, 2011b; Milliman, Inc., 2014). The results of the Enrollment and Utilization Projection Models are combined to generate an estimate of the quantity of medical services that enrollees will want to obtain from VHA (that is, the quantity of medical services demanded), annually for 10 years. The Unit Cost Projection Model is then used to translate the quantity of services demanded into an estimated cost of delivering those services in each year.

Enrollment Projection Model. This model divides the Veteran population into enrolled and non-enrolled pools and then calculates new enrollment by applying the historical enrollment rate to the non-enrolled pool. In any fiscal year, expected enrollment is equal to current enrollment plus net new enrollment. Age, VA benefits eligibility, geographic area, and special conflict status are the four main demographic characteristics used to calculate the enrollment rates.

Utilization Projection Model. This model uses utilization data from the recent prior time period for a variety of service categories (Harris, Galasso, & Eibner, 2008). Milliman estimates utilization rates by compiling utilization data from a variety of sources, including VA, Medicare, and commercial claims databases. Utilization rates for the approximately one-half of VA users who are age 65 or older are developed from combined VA and Medicare data for this population. Utilization rates for younger users are adjusted from Milliman's proprietary rates based on commercial health plan data. The adjustments reflect differences in the VA population compared with the general population (which obtains health care from the private sector). The model determines a VHA-specific utilization rate by service, which is then applied

---

to the projected average number of enrollees. The utilization projection also incorporates variation according to geographic location, benefits, age, gender, morbidity, and reliance on VA health care versus other sources of care to which enrollees have access.

Unit Cost Projection Model. The third submodel derives detailed VA unit costs on the basis of VA's Decision Support System direct costs, Medicare-allowable charges, and charges non-VA providers bill VA in various health care services categories. The derivation also involves a comprehensive set of adjustments to account for the characteristics of VA health care services and case-mix. Total projected expenditures in a given projection year are obtained by multiplying the estimated enrollment, utilization rate, and unit costs.

Concerns about the EHCPM. A number of concerns have been raised about the EHCPM. The model is proprietary and highly complex, so it is difficult to evaluate (Harris, Galasso, & Eibner, 2008). Substantial and detailed adjustments are required to adapt commercial health plan utilization data to the VA enrolled population under age 65, who have different health needs and use VA for only some of their health care. Assessment A discusses these problems in further detail. The utilization rates for Medicare-age enrollees, which are measured from data on utilization of VA and other providers through Medicare, are more directly tied to actual service use by this population.

VA constructs unit costs based on a combination of VA's Decision Support System financial data for services VA provides that others do not (such as some mental health or special prosthetic programs). VA uses Medicare or community payment rates for some of the more granular levels of detail. The average cost for a given service goes through a variety of adjustments to account for geographic location or to reflect the additional needs of sicker patients. Harris, Galasso, and Eibner (2008) found that the unit cost approach does not take into account the true marginal cost of increased utilization, which would have to include whether there was enough space for staff to see more patients, or whether more expensive equipment would be needed.

The EHCPM also uses available data to project forward several years into the future. VA uses separate trend adjustments to account for changes in medical inflation and utilization rates for particular services. Since projections are based on the current allocation, the amount budgeted and subsequently funded will be adequate only if the current budget is adequate and the assumptions used to estimate trends are correct. Otherwise, it may take several years for the errors to be recognized. For example, among those who have other insurance, reliance on VA for services can vary over time, and major U.S. policy changes, such as the 2010 Patient Protection and Affordable Care Act, can impact reliance on VA if there is a resulting increase in the number of younger Veterans with other insurance.

Assessment A analyzed data on the Veteran population, enrollment, and use of VA health care and developed projections through 2024. For many years, VA has seen a steady trend upward in the number of Veterans enrolling and using VA health care, even while the total Veteran population has steadily decreased. If this upward trend continues at a steady rate, EHCPM will account for this trend appropriately. However, if the trend accelerates (as it did in the years before and after 2000), the budget projection will fall short of what is needed to maintain access. The analysis in Assessment A identifies reasons for uncertainty in projecting the number

of users in future years, but concludes that the upward trend is likely to end in the next decade. In this case, future budget requests are less likely to fall short of requirements.

Facilities capital improvements and IT budgets. These items are budgeted separately from the EHCPM, often using prior trends to budget for major line items, such as facility maintenance and administrative costs. Budgeting these items separately means the needs of facilities in terms of having a completed building lease in which to house new staff may not be completed in a coordinated fashion (GAO, 2011b). The facilities capital improvements budget is developed through the master plan, which includes major and minor construction projects and nonrecurring maintenance projects such as renovation of existing facilities. Recurring maintenance is part of the overall medical care budget and includes funding for maintenance, engineering services, linen cleaning, etc. The IT budget is developed for the whole VA through the board of the Office of Information and Technology (Department of Veterans Affairs, Office of Information and Technology, 2014).

Assessments K and H discuss the budgeting process for facilities and IT, respectively, in greater detail. Assessment H found that VA should revise the planning and budgeting process to ensure business needs are effectively identified, prioritized, and funded and used to drive IT investments. Assessment K found that there is a shortfall between the actual budgeted amount and the amount needed to adequately maintain older buildings, and this gap is projected to widen over time. Assessment K also found that VA could more efficiently use existing space by outsourcing facility maintenance or operating administration.

Payments from third-party payers. VA gains a small portion (approximately 5 percent, or $3.2 billion, of the $63 billion for FY 2016) of its budget through collections from third-party payers for non-service-connected care at VA facilities and copayments for various services (VA, 2015a; VA, 2014e). VA is mandated to cover the costs of care provided to Veterans with disabilities rated at 50 percent or higher, to certain other groups of Veterans, and for service-connected medical conditions. The Balanced Budget Act of 1997, however, authorized VHA to bill private insurers and collect copayments for non-service-connected care. This collection is deposited to the Medical Care Collections Fund to cover expenses for providing the medical care with no fiscal year limit.

VA is prevented by law from billing Medicare (fee-for-service or Medicare Advantage plans), the main source of other insurance for Veterans (VA, 2015a).[13] Since Medicare Advantage plans are paid a capitated rate for providing care to all enrollees, the government is paying twice for the same services when Veteran enrollees instead use VHA. A study found that half of the Veterans enrolled in both VA and Medicare Advantage plans used both systems to access care (Trivedi et al., 2012).

There are various initiatives within VHA to improve the collection of both copayments and payments from third-party payers—issues that Assessment I describes further. The process has

---

[13] VA, however, is allowed to bill private supplemental insurers ("Medigap" plans) for non-service-connected medical care.

not always gone smoothly. A 2004 GAO report studied the costs associated with collecting payments from third-party payers for the Medical Cost Collections Fund (GAO, 2004a). The report found that many VISNs underreported the cost of collecting these claims. The report recommended that VHA improve the uniformity of the collections process by issuing guidelines concerning which costs associated with collections should be reported.

3.1.1.2 Current Funding Level

The FY 2016 advanced appropriation includes $49 billion for medical services, $6.2 billion for medical support and compliance, $5.0 billion for medical facilities, and $3.2 billion in collections (VHA, 2015a). Table 3.1-1 details the major operations categories and the estimated budget for 2015 along with either revised requests or advance appropriation amounts for FY 2016 and FY 2017. For FY 2016, the advanced appropriation of $63.1 billion is a 7-percent increase above the FY 2015 enacted level. The advanced appropriation is a request, and the level of funding is dependent on Congressional approval.

Table 3.1-1. Major Categories of VA Budget Allocation (in Millions)

Fund Account	2015 Request	2016 Advance Approp.	2016 Revised Request	2017 Advance Approp. Request
Medical Services	$45,383	$47,603	$48,727	$51,673
MCCF Collections	$3,048	$3,253	$3,227	$3,300
Medical Services (with collections)	$48,431	$50,856	$51,954	$54,973
Less: Veterans Choice Act	*($740)*	*N/A*	*($1,573)*	*N/A*
Subtotal	**$47,691**	**$50,856**	**$50,381**	**$54,973**
Medical Support & Compliance	$5,880	$6,144	$6,214	$6,524
Less: Veterans Choice Act	*($11)*	*N/A*	*($17)*	*N/A*
Subtotal	**$5,869**	**$6,144**	**$6,197**	**$6,524**
Medical Facilities	$4,739	$4,915	$5,020	$5,074
Less: Veterans Choice Act	*($1,017)*	*N/A*	*($775)*	*N/A*
Subtotal	**$3,722**	**$4,915**	**$4,245**	**$5,074**
Total	**$59,639**	**$61,915**	**$63,810**	**$66,571**
Total, less Choice Act	**$57,871**	**$61,915**	**$61,445**	**$66,571**

Source: Reproduced from the FY 2016 VA budget request (VA, 2015a).
Note: The estimates for the Choice Act do not include some funds for IT and facilities, so the total does not add to $5 billion.

The Veterans Choice Act is expected to affect spending in several areas, including medical services and facilities. The Veterans Choice Act allocated $5 billion for VA to use in directly providing medical services, including hiring more than 9,600 new providers in primary care, specialty care, and mental health care.[14] The breakdown of part of the $5 billion is shown in Table 3.1-1, in the form of subtractions (substitutions) from the 2015 and 2016 budgets. The Act also allocated $10 billion to be spent on private-sector health services. If the Veterans Choice Act increases demand for purchased care, meaning that some Veterans access services through the community that they would otherwise have accessed through VHA, this may transfer additional spending from VA's existing budget. The estimates of the transfer amount range from $452 million to $733 million in 2017 (VA, 2015a). However, these estimates are uncertain, as the number of Veterans who will ultimately access the program is unknown.

Spending on additional resources for VA care funded by the Veterans Choice Act will need to be incorporated into budget requests for FY 2018, which are now being developed for inclusion in the President's 2017 Budget. The additional funds for the Veterans Choice Cards were not funded through the regular appropriations process. As a result, it is unclear how the overall budgeting process will be affected after these funds are exhausted. The Congressional Budget Office estimated that the increase in VHA spending would be approximately $42 billion over the 2014–2017 period, derived from both the additional ability of Veterans to use purchased care and the money allocated to hire additional staff within VHA (Congressional Budget Office, 2014).

3.1.1.3 Congressional Priorities and Their Impact on the Budget

The GAO has stated that, "Budgeting is and will remain an exercise in political choice, in which performance can be one, but not necessarily the only, factor underlying decisions" (GAO, 2002b). Congressional priorities can affect the budget both through the overall level of appropriation and by authorizing extra spending, as was done with the Veterans Choice Act. Hearings also give Congress the opportunity to emphasize certain programs or to raise or address constituent concerns. Ultimately, because VA is one of many federal departments, the funding for VA is affected not only VA's request and congressional priorities for VA, but also the needs of other departments and programs included in the federal budget.

Recent areas of concern. For the 113th and 114th Congresses, the major areas of recent concern in terms of medical services are access (both wait times for appointments and travel distance), quality of and access to behavioral health services, and the ability of VA and DoD medical information systems to talk with each other. We focus here on wait times and geographic accessibility for Veterans because these concerns have led to the most-recent direct congressional action affecting the VA budget.

As a result of concerns over wait times for appointments and geographic accessibility, Congress passed the Veterans Choice Act in 2014, which, as described above, provided additional funding

---

[14] Section 801 provides $5 billion for spending on hiring more physicians and improvements in infrastructure. Section 802 provided $10 billion for purchased care.

to VA both to increase the use of non-VA providers ($10 billion) over three years and to hire more clinical and support staff in-house ($5 billion). Interviews with congressional experts noted that the Veterans Choice Act added another layer to existing purchased care programs. Congressional experts said that the enactment of the Veterans Choice Act means that, eventually, all the purchased care programs, such as PC3 or the traditional purchased care program, will have to be reconciled, since they are attempting to achieve the same goals.

The Veterans Choice Act provided three years of mandatory spending for VA. Since VA is typically funded from discretionary funds in the appropriations bills, after three years, ongoing increases in spending for activities derived from the Veterans Choice Act will have to come from discretionary funds. This has the potential to affect the overall adequacy of VA funding if the budget is not increased to account for ongoing costs related to the Veterans Choice Act, particularly since the act required the hiring of additional providers, which will lead to recurring costs in the budget going forward. Congressional experts said that, in the long term, the VA discretionary appropriation will have to fund these costs. If the purchased care funded through the Veterans Choice Act is extended, the presumption is that Congress will fund it. The additional staff will have to be incorporated into VA's existing budget projection models (the EHPCM, discussed above), leading to increases in VA's overall budget.

In general, Congress does not give VA specific earmarks or funds to be spent on specific services, except for purchased care through the Veterans Choice Act. However, the committee hearings process gives VA direction on where Congress *would like* to see emphasis placed. In turn, the VA Central Office can respond with directives to emphasize certain programs or service lines. The Central Office can also allocate funds that have to be spent for specific purposes, thus being directly responsive to congressional concerns. Many facilities, however, view these funds as taking away from direct patient care. This will be discussed in the subsection on allocation below.

In summary, the main issues identified with the VA budget process include concerns about the data used for budget planning and inflexibility in budgeting stemming from the congressional appropriation processes. VHA develops its budget from older data, and there can be problems with the assumptions used in this process. In addition, Congress can influence VA through the agency's overall appropriation, by providing extra funding off-cycle or by emphasizing specific priorities through the hearings process. Issues highlighted during the hearings process are often turned into special purpose funds from the VA Central Office.

3.1.2   Allocation of Funds

In the previous subsection, we described how the budget is formulated and enacted. We now turn to a discussion of VA's process for allocating the congressional appropriation to the VISNs, which is a separate process from the one used for budget formulation. We also discuss issues with the allocation process that may lead to constraints at the VISN and facility level. Finally, we discuss other constraints not related to the allocation process, but that can also hamper facilities' effective use of fiscal resources.

3.1.2.1   Allocation Process

Once Congress approves the overall appropriation, VA allocates funding to the VISNs through the Veterans Equitable Resource Allocation (VERA) model. This is a separate process and formula from the EHCPM, which is used to develop the overall budget. These models operate independently, as they serve different purposes. The VERA model serves to split the VA "budget pie" into equitable pieces, using a capitated-style model, while the EHPCM is designed to formulate the size of the overall "pie." Capitation is a process through which health insurance plans pay providers a set fee per person per year, which may be adjusted for health risks. Capitation arrangements incentivize health providers to manage their patients' overall utilization, as any unused funds become profit at the end of the year. VERA differs in several important ways from the usual capitation system. It allocates funding based on actual users, excluding enrollees in the area served by the VISN who do not receive any care. Because patients in different VISNs have a different mix of health care, the model incorporates a risk adjustment formula. Because VA patients obtain only some of their care from VA, this formula is based on the medical conditions treated at VA. Finally, VA has the aligned incentives of an integrated system with capitated payments, but not the same incentive to manage utilization to the point of expecting profits at the end of the year—all funds need to be obligated or spent.

Under VERA, the general purpose funding for medical care is allocated based on the number and types of patients treated and includes funds for administration and some facility maintenance. Specific purpose funds are allocated separately according to special legal or programmatic requirements, national support functions, and projects for which VA thinks that economies of scale can be achieved at a national level.

Patients are classified into types according to health condition, severity, age, and priority group, and the VISN receives an expected payment per patient type per year (2014 VERA Book [VA, 2014j]).[15] Specific purpose funds are allocated for a variety of programs, including prosthetics, rural health, and homelessness. Patients are broken out into 60 categories of health conditions and then rolled up into 10 price groups based on severity of condition. The 10 main groups roll up into the three main categories of complex care, basic vested care, and basic nonreliant care.[16] Complex care is the most expensive category, and these patients account for 4 percent or less of the VHA population but about one-quarter of the spending (2014 VERA Book [VA, 2014j)].

Table 3.1-2 summarizes the payment per patient for each of the 10 condition groups, as well as an example condition or service under the condition group. The payment per patient in each category is calculated using the proportion of total funds each group costs using VA's internal data. There are adjustments for location-specific differences in labor costs and high-cost patients. High-cost patients are defined as those in the top 1 percent of spending for priority

---

[15] Priority groups establish eligibility for VA health care based on service-connected disability, income, and other factors.

[16] The term *vested* reflects those Veterans receiving the majority of their care at VA.

---

groups 1 through 6, or those with very long stays in community living centers. The threshold for the 2014 VERA model was based on utilization from 2012, with a threshold amount of $108,000 for standard cases and $242,000 for long stays in the community living centers (2014 VERA Book [VA, 2014j]).

Table 3.1-2. VERA Allocation Amounts per Condition Group

Price Groups	Diagnosis Example	Priority Groups 1–6	Priority Groups 7–8
1. Non-Reliant	Pharmacy use only	$291	$222
2. Basic Medical, Heart, Lung & GI	Cardiovascular disease	$2,729	$1,621
3. Mental Health	Addictive disorders	$3,534	$2,394
4. Oncology, Legally Blind	Oncology	$5,094	$3,339
5. Multiple Problem	Multiple medical	$12,214	$10,059
6. Significant Diagnosis	Metastatic cancer	$21,730	$17,447
7. Specialized Care	Stroke	$16,373	$11,824
8. Supportive Care	Needs home-based primary care	$30,096	$22,197
9. Chronic Mental Illness	Schizophrenia & dementia	$28,902	$28,902
10. Critically Ill	Polytrauma	$64,518	$60,639
10a. Long Stay Community Living Center	Nursing home care	$166,261	$166,261

Source: Reproduced from VA's 2014 VERA Book (VA, 2014j).

Note: *Non-reliant* indicates those who receive the majority of their care outside VA facilities in Priority Groups 7–8.

3.1.2.2   Allocation Levels

The VERA model in 2014 allocated 78 percent of the medical services funds from the congressional appropriation, with 22 percent withheld for the specific purpose funds. VISNs also received transformation funds to support initiatives to improve the coordination of and access to health care (for example, patient aligned care teams, telehealth). As discussed earlier, VISNs also oversee collection of copayments and, in some cases, billing of third parties for non-service-related care provided by VA. Table 3.1-3 shows estimates of the funds received by each VISN in each of these categories for FY 2014, the year for the latest VERA data. Table 3.1-3 shows that there was some reallocation of funding during the year from geographic areas with lower than expected levels of population served or lower utilization relative to areas whose utilization was higher than expected.

Table 3.1-3. VERA Allocations, Specific Purpose, Transformation, and Estimated Receipts, by VISN, FY 2014 (in millions)

VISN	FY 2014 VERA General Purpose Total*	FY 2014 Specific Purpose*	FY 2014 Trans-formation*	FY 2014 Projected Collections	FY 2014 Projected Reimbursements	FY 2014 Projected Totals	Total % Change from FY 2013 to FY 2014
01 Boston	$1,995	$323	$9	$125	$6	$2,458	0.3
02 Albany	$935	$155	$7	$54	$3	$1,154	2.4
03 Bronx	$1,637	$284	$10	$92	$9	$2,032	−1.7
04 Pittsburgh	$2,010	$289	$8	$121	$7	$2,434	−2.5
05 Baltimore	$1,122	$235	$4	$78	$5	$1,443	2.7
06 Durham	$2,247	$431	$18	$209	$7	$2,913	3.4
07 Atlanta	$2,479	$433	$13	$178	$10	$3,112	3.5
08 Bay Pines	$3,567	$620	$9	$290	$38	$4,524	−2.0
09 Nashville	$1,879	$286	$7	$155	$11	$2,338	0.0
10 Cincinnati	$1,660	$217	$10	$110	$7	$2,004	0.6
11 Ann Arbor	$1,756	$272	$13	$113	$3	$2,157	2.9
12 Chicago	$1,915	$357	$5	$168	$18	$2,462	2.2

Source: VA's 2014 VERA Book (VA, 2014j).

Notes: *Values are estimates, reported prior to the end of the fiscal year. VISNs 13 and 14 do not exist, as they were combined into VISN 23.

The VERA model governs allocations from VHA to the VISN level. VISNs, in turn, govern the allocation to facilities. Prior to 2011, each VISN could vary in how it weighted different criteria in determining the allocation, including funding in the previous year, workload, and square footage of the facility. In 2011, VA introduced a new model, called the Medical Center Allocation System, to distribute VERA funding from the VISN to facilities; this mode included a new measure of workload called "patient-weighted work" (2014 VERA Book [VA, 2014j]). The measure took existing measures for resource-adjusted workload and added factors for high-resource-intensity patients, differences in costs at the facility level, and a facility complexity level. This facility-level model has not been reviewed extensively, though in 2011 GAO did review the initial phase of the process and found that networks were adjusting the amounts for particular facilities after the Medical Center Allocation System calculation had been done without adequate documentation for the reasons (GAO, 2011a).

While the VERA model allocates funding for medical services, the budgets for capital planning and IT are handled through separate processes for the whole VA (not just VHA). IT projects are developed according to a strategic plan and are prioritized by IT Investment Governance Boards (Department of Veterans Affairs, Office of Information and Technology, 2014). Assessment K discusses in greater detail the process for capital improvements to facilities. In summary, the requests for capital projects are put on the prioritized list of projects called the Strategic Capital Investment Plan, which was established in 2012 (VA, 2015c). The process includes an analysis of facility-level gaps in space, workload/utilization, access levels, and even wait times and compares them with capital assessment and strategic plan. Projects are prioritized according to six criteria ranging from improving safety and security to "rightsizing" the inventory. While the total budget for major and minor capital outlays is under $5 billion for 2015, the facilities budget estimates that over $50 billion would be needed to complete all projects based on current market conditions (VA, 2015c).

3.1.2.3   Issues in the Allocation System

In interviews, facility directors described three main concerns with the VERA allocation system to the VISNs. The first is that the time lag in calculating the allocation can leave some facilities underfunded if their Veteran populations are growing quickly. Facilities are cognizant of the need to undertake various activities to ensure that their allocation is as high as possible in subsequent years. These may take the form of seeing more patients for more medical conditions or providing more services for the same patients and medical conditions to obtain a higher allocation from the VISN. To the extent that all facilities behave in this way, the allocations will not change much in the short run because the budget is fixed. Over the longer run, however, the behavior could increase the budget projected by EHCPM.

The VERA model was originally created to reduce geographic inequities in funding, given the shift of Veterans from the northeast to the south and west and the potential for cost differences related to climate and local health labor markets. Since its inception in the late 1990s, the VERA model has been updated based on feedback from a series of RAND and GAO reports (GAO, 1997a; Wasserman et al., 2001; Wasserman et al., 2003; Wasserman et al., 2004). Initial improvements to the model increased the number of patient classification categories from three to 10 to better identify the health risks of the population, and included

extra payments for patients with outlier spending (Wasserman et al., 2004). A 2002 GAO report noted that, because VERA is in part based on workload, VA facilities were incentivized to see more patients, which may be good if the increased workload alleviates access problems (GAO, 2002a). The report noted three key concerns, however, including the need for better identification of workload, adjustments for age of facility, and accounting for the degree to which Veterans seek care through VA rather than seeing non-VA providers using other forms of insurance. If Veterans are more reliant on VA and using more VA services, the costs will increase. Both these factors can potentially influence the costs of caring for patients in a given year, but may not be reflected in the VERA allocation.

Using older data. While the VERA system is largely viewed as an equitable way to divide a fixed budget, it is important to note that the system used with VERA is relying on past data rather than the same projected data used in the EHPCM. For example, the population counts for the 2014 allocation for basic care use the average number of users from 2010–2012, whereas complex care patients use a five-year average. This process can leave VISNs over- or underfunded in a given year if demand is changing rapidly unless VA can reallocate funding from other VISNs. It will be able to do this only if the aggregate funding is high enough. Other systems would provide a set fee (adjusted for health status) for all expected enrollees, regardless of whether they actually use any services. While VERA does attempt to predict workload, this time lag can leave certain networks and facilities that experience strong demographic shifts with insufficient funding. Many facility leaders interviewed noted the two-year time lag in the VERA allocations as a problem for areas that are growing quickly. For example, one respondent said the process caused them to start the year with a projected deficit:

> We had to take some steps locally to deal with that and delayed some funding of programs, that type of thing, to make sure we were going to close the year out—and we'll do fine now. But dealing with the increased workload that we're experiencing in conjunction with having budget challenges obviously makes for some very tough decisions.

Other issues. Respondents noted that their facilities were performing various activities to ensure that the VERA allocation was as high as possible. For facilities that are losing patients due to being in areas with poorer weather or less favorable economic conditions, there is pressure to maintain a patient load:

> We lose Veterans constantly during the year to death, to out-migration, and to changing patterns of the Veterans that sometimes they don't need to use us. They have private health insurance and they won't come to us. So that's constantly changing during the year but we lose about 3,000 Veterans per year and we replace at least those 3,000 and usually a couple hundred more.

In addition to losing patients to other areas, some facility directors said that, to ensure that their allocation better reflects their actual utilization, they are conscious to code services accurately: "Probably about five years ago we started looking at a lot of the things that impact VERA to make sure that we were maximizing . . . or we were documenting correctly, we were coding correctly, we were getting everything completed within the amount of time to capture the appropriate workload." It should be noted, however, that the coding systems in VA have

not worked particularly well, and Assessment I examines this issue in further detail. Additionally, Assessment G found that VA providers may not fully document and accurately code all of their clinical workload.

Respondents even suggested that there is some degree of including additional services to hit various workload levels:

> So there's different facilities in the system that have learned to ensure to maybe have a consult from surgery. After surgery was done you do a home-based primary care visit, 10 visits over maybe three weeks to make sure that they're up and running but then you're going to get reimbursed for that and your VERA value is going to be higher.

The process of adding services can also lead to attracting patients with more-complex needs in order to increase funding levels. However, this is likely to be a zero-sum proposition across VISNs in the short run until the budget projection model can incorporate the increases in severity of patients and increase the overall budget request.

> If we hire a cardiologist, is that going to attract more Veterans to us for cardiology services, which then turns into the VERA process, you know, they look at that and you're funded two years down the road [and] because you have additional Veterans coming in who have additional complexity and this is where you get your funding from.

While many respondents felt that the VERA methodology left them at a disadvantage, it should be noted that this concern was not uniform. Other respondents said that the VISNs are able to fill in funding gaps:

> What usually happens, at least from my experiences at the network or the VISN level, through their methodologies to distribute the VERA monies, those things can be somewhat smoothed and the VISN and the medical center can be a little bit more responsive, as far as to the real-time needs.

Others say that the VERA model is doing a relatively good job of gauging the workload and cost of doing business in different areas of the country:

> In that VERA funding model, I understand there is a component piece that is just for rural aspects of health care. That actually gives you a little bit of a bump and allows you to earn a little bit more, recognizing that costs in rural America are higher than other places.

3.1.2.4 Additional Funding Constraints

Through interviews with facility leaders, we identified several other constraints to using allocated funds efficiently at the facility level. Most facilities identified an inability to use their budgets flexibly across pots of money for IT, facilities, and medical care. Facility leaders felt that the capital planning process is misaligned with the budget process and said that they are not able to roll over funds from one year to the next. Finally, many respondents also noted that many, but not all, centralized VA processes were a barrier to providing adequate patient care. We discuss each of these issues here.

Lack of flexibility in spending. As described above, at a broad level, the VA appropriation for VHA is divided into accounts for medical care, medical support and compliance, and some

---

nonrecurring maintenance. The money is not fungible across domains because of appropriations law: "Appropriations shall be applied only to the objects for which the appropriations were made except as otherwise provided by law" (U.S. Code Title 31, Section 1301). For example, a VA Office of Inspector General report found that the Chief Business Office was in violation when it used $92.5 million to build a claims processing system. The violation was due to using funds from the Medical Support and Compliance appropriation rather than the IT Systems appropriations (VA Office of Inspector General, 2015b).

Many facility leaders said the inability to shift money between the major allocation line items, such as maintenance and medical services, makes it difficult to adequately manage the budget in a year:

> The pots of money, they've got to stop. . . . If you would actually trust the individuals that you have put in place to run your hospitals and realize what those resources were needed for that certain facility, then you would be able to manage it much better.

Another respondent noted that the lack of flexibility is detrimental to their ability to respond quickly to workload shifts:

> We have so many various appropriations in fenced money that it makes it very difficult in the field to deal operationally with your finance. So what it does is it really ties the hands of the facility and VISN leadership in making decisions quickly in response to workload shifts and that type of thing, because money is tied up in special purpose or fenced. That is a huge, huge issue I think for VHA.

Special purpose funds. VA facility leadership we interviewed believe that the special programs money take away from the overall budget for patient care: "They'll take money off the top and then allocate that money to the fields to provide seed money to start new programs, which is good. The problem is then they hire three people in D.C. to manage that program." Many respondents said VA Central Office initiatives removed flexibility from their budget and planning process:

> So they decide what your needs are, they decide that you need 15 mental health providers and say, "Here you go. You can only spend this money on this." And then at the end of the year if you didn't necessarily need that, you can't use the money for different operations somewhere else. You would have to return that money to Central Office.

One director said that, even if there is funding, in addition to having enough demand for the given service, the extra money may come without any regard to the physical space or IT requirements needed to fulfill the request: "[With the Veterans Choice Act money] we've been given the dollars to hire additional staff and in many cases people think, 'Where am I going to put them?'" Another respondent stated that their facility was told to hire more than 150 new staff for mental health:

> And in order to do that we're putting up modular buildings until the space is available. Then we can start bringing the people onboard. But you can't recruit until you have that space to accommodate that staff. So it works great when the money comes at the beginning of the fiscal year. You have time to plan well and you've got the space. But

when it comes at a very restricted time or the timeline is very short it makes it a challenge.

Finally, one respondent noted that requests from the Central Office may also come without enough or any funding attached:

The expectations on those mandates come that you are to address them immediately. . . . You're given a budget and you are reminded all the time that you have to stay within this budget; you have to manage within this budget. Usually then you go to staffing because that's where most of your budget is allocated to. And so where do you cut staffing, or where do you delay bringing people onboard? And that always impacts on quality of patient care.

While many facility leaders expressed frustration at the special purpose monies being diverted from the overall pot of money to be allocated through VERA, Central Office officials did say that some of the special purpose funding allows VA to respond to both congressional and Veteran Service Organization groups in a timely way:

It all ends up back in the field. It is just managed centrally, so although there is a tug sometimes because every VISN and every facility would like to get their money un-earmarked, if you will. "Don't tell me how much to spend on prosthetics. I will figure that out myself. Just give me the money," so there is that dynamic tension, but we seem to vet that out pretty well by making sure that what is in specific purpose is either required by law or some other special motivating factor.

Difficulty in funding new construction or renovations. Many respondents said that the ability to quickly approve facilities and IT requests would help them expand capacity in areas where it is needed most. The facilities master plan approves major and minor construction projects. It can take years for the process to authorize a project. An audit from the VA Office of Inspector General found that construction projects were often not well managed and needed more oversight (VA, Office of Inspector General, 2014a). The report indicates that the time required to insert projects into the timeline can mean that the final project may have no correlation to current demand:

Although projects under $1 million are selected and approved annually, a [Strategic Capital Investment Plan] project proposal submitted in FY 2014 will be scored, and if approved in FY 2015, will receive design funds in FY 2016 and construction funds in FY 2017 (page 9).

Many respondents also described the process for getting new buildings or major renovations into the capital strategic plan as cumbersome:

As the director of an organization, of a health care system, that if we identify a need to lease an extra 10,000 square feet to meet the demand and provide the source to the Veterans, it shouldn't take at the level of the deputy secretary to loop things quickly through the organization.

As a result, many respondents said the space constraints negatively affect their ability to hire providers: "The number of Veterans we're seeing is increasing, yet you can't add new parking, you can't add new offices, you can't add new exam rooms in a reasonable, even an

unreasonable, amount of time." Planning for new space can be difficult for facility leadership to anticipate:

> You know, you try to plan as much as you can in advance, but you just can't read the tea leaves all the time. And so when you try to make adjustments to clinics, to facilities, it's a multiyear approval and funding process, before you even get into construction. That slows us down.

No incentive to save for capital planning. While VA is similar to other capitated systems, such as a health maintenance organization (HMO), money not used on patient care at the end of the year cannot be saved and put toward new equipment or capital planning. Funds have to be obligated fairly quickly in the year in a "use-it-or-lose-it" fashion:

> You have to compete with all the other facilities across the country and then Congress decides what they're actually going to fund for that year and it may be two to three years down the line. So if I was running a private-sector hospital, I would be able to utilize a variety of different funding methods to do this, but it doesn't even benefit me to save resources during the year because I can't apply that to any of the following years.

Beyond saving money for capital projects, the critique about the lack of incentive to save money was also noted for within-year funding, so that there are no reserves at the facility level for emergencies, because all the funds have to be obligated six months into the year:

> I understand that we can't show Congress that we have all this equipment money sitting there at the end of the year, but having to have it obligated and spent in the first six months makes absolutely no sense. You need to hold onto a little bit in case something bad happens, something breaks, something goes wrong.

While there is a drive to obligate money as quickly as possible, some facility leaders said they readied a list of additional equipment or projects to absorb any last-minute funding. Respondents noted that there can be a rush to spend extra money at the end of the year: "The other thing is that sometimes then in late-August/mid-August, and all of the sudden they say, 'We've got money but you've got to spend it by September the 30th.' We've learned how to deal with that because it's happened year after year."

Centralized processes that take time away from patient care. IT, like capital infrastructure, does not all come from the same pot of money. As a result, managing the IT resources is challenging, as is requesting new items: "We need the ability to manage the IT budget in conjunction with the business." Another respondent noted that the centralized IT process across all of VA creates its own problems.

> So the disconnect you have is, we put money in the budget to buy more telehealth medical equipment. We get it. We don't score high enough in [the Office of Information and Technology], so we don't get the pipelines [bandwidth], if you will, and so we end up with equipment we can't fully utilize or we can't utilize it to maximum capacity if we've got small lines.

Beyond the centralized processes for facilities and IT requests, many respondents expressed frustration with the central contracting office. One respondent said the contracting process is a barrier to effective and timely care:

> I've got an issue on my desk right now where I've got a patient I need to send out to a long-term acute facility, not a typical community nursing home. We'll have to do an emergency contract, make phone calls every single day to get this done in two months. . . . You know how much executive time, not just for me but my associate director, the Chief of Staff, chief of social work, chief of logistics, calling around, doing . . . that is insane and this is something we have created within the VA.

Other concerns about the contracting process included the extensive reporting requirements and the requirements to prioritize small businesses for contracting in rural areas. One respondent summarized the situation as difficult at best:

> [The] simpler the process can be made to be, the better our Veterans will benefit. So as we go to pay bills, as we enter into contracts, the magnitude of things we have to do to expend that money on behalf of our Veterans sometimes slows the process and gets in the way. But we understand we're a public entity with a trust and that we have to do our due diligence to ensure that we're following the law, but that comes at an expense of the speed and volume of care.

Despite these findings from facility leadership on the difficulty in dealing with central processes, it is not necessarily true that all centralized processes are inefficient. For example, Central Office officials highlight that there may be efficiencies in centralizing certain business processes such as billing or paying claims for purchasing care from non-VA providers: "We looked at the fee basis care program . . . it was three or four years ago, and basically found that it was total chaos. And part of what was recommended there was greater standardization and more consistency because that is an area where there should be more consistency."

3.1.3 Comparing the Adequacy of VA's Health Spending with Private-Sector Spending

In the previous subsections, we discussed the budget development and allocation processes and described various problems with the allocation process that can cause facilities to be over- or under budgeted in a particular year. These problems include the time lag in the data, incentives for facilities to increase workload to increase future funding, and large maintenance costs for older buildings. However, these analyses do not directly answer the question of whether VA has enough money to provide timely and accessible care.

To answer this key question, we would need some benchmark against which to compare VA's costs of care. There is no natural comparator, given the integrated delivery system of VA, with its differences in population. There are other integrated delivery systems, such as Kaiser Permanente or Geisinger Health, but their beneficiaries generally receive all their care from their system, something that is not true for VA. This limits the value of such comparisons. The differences in the Veteran population compared with the private-sector population are discussed in detail in Assessment A. In 2011, the Congressional Budget Office estimated that the spending on Veterans of recent conflicts in Iraq and Afghanistan could total $40–55 billion from 2011 to 2020, since advances in technology have allowed many service members to survive injuries that were previously fatal (Congressional Budget Office, 2011).

Over the past two decades, many studies have attempted to address the question of whether VA care is more cost-effective than the same care would have been if purchased from the private sector; these studies have produced divergent findings. A 2009 study found that overall VA health costs and inpatient services costs are substantially higher than in the private sector (33 percent and 56 percent, respectively), but drugs prices are lower in VA (Weeks et al., 2009). In contrast, other studies have found that the cost of care provided in VA is lower. In an earlier set of articles in *Medical Care* in 2003–2004, the authors concluded that the cost to taxpayers for VHA services would be 15.6 percent higher if the same set of services were provided at Medicare payment rates (Render, Roselle, Franchi, & Nugent, 2003; Render, Taylor, Plunkett, & Nugent, 2003; Hendricks, Whitford, & Nugent, 2003; Nugent, Grippen, Paris, & Mitchell, 2003; Roselle et al., 2003; Nugent, 2004). A major driver of the difference in costs at the time was drug prices, since VHA negotiates lower prices for pharmaceuticals, and, at that time, Medicare's Part D drug benefit had not yet been enacted. Even now that Part D has been implemented, however, the price for VHA drugs is still lower than Medicare's; Medicare is prohibited from negotiating drug prices as VHA does.

The studies have similar methodologies, which is to price the same "basket" of services in either Medicare or the private sector. Weeks et al. (2009) estimated VA costs by determining the proportion of spending on the particular service and then dividing this by the number who received the service. They used the Medical Expenditure Panel Survey to estimate the cost in the private fee-for-service environment for the same basket of services. The *Medical Care* series of articles used Medicare allowed amounts for services and did a microcosting study to document the variety of services VA provided that do not ordinarily show up in administrative records because VA does not have to bill for them as an integrated delivery system. Both these methods fail to control for the variety of other costs, such as benefits for employees or the severity of patients that may make private-sector or Medicare estimates lower or higher.

Comparisons to the private sector, such as those described in these studies, are difficult to interpret because having lower spending is not necessarily an indication of more efficient spending. The Congressional Budget Office found that comparing per capita spending between VA and the private sector can be misleading because of differences in patient populations served and the fact that many Veterans, including users of VA health care, have at least part of their medical needs met at private facilities through Medicare or private insurance (Congressional Budget Office, 2014). The Congressional Budget Office found that comparing the costs of care for particular services (the cost of providing the service rather than total spending, which would include the quantity of services and their prices) can be a better approach. However, the Congressional Budget Office found that even this approach can be problematic because VA is an integrated delivery system, so not all services are assigned unit costs as they would be in a fee-for-service environment. Additionally, incentives are more aligned in integrated delivery systems, which can affect the intensity of services for each procedure. Thus, we conclude that comparisons of VA spending with that in the private sector are not valid ways of measuring whether VA has enough resources to provide timely and accessible care to Veterans.

3.1.4 Subsection Summary

VA is funded through annual congressional appropriations. Congress approves the overall VA budget, adjusting it up or down. Assuming that VA has requested enough money to meet its needs, and that Congress approves the budget, VA then allocates the money to its care networks VISNs and then to facilities. In passing the Veterans Choice Act in 2014, Congress, in an unusual step, provided additional funds through a mandatory appropriation to be spent over three years.

We were not able to determine whether VA has adequate fiscal resources for health care, given Veteran demand. There is no objective measure or benchmark against which to compare VA's budget and spending to know whether it has sufficient funding to provide timely and accessible care. Additionally, data are not available to measure unmet demand due to access barriers (not enough funding) or to assess the productivity of VA in delivering health care services with its current level of resources (not efficient at using existing resources). Shortcomings in the data for assessing access are discussed further in Section 4 of this report and in Assessment D's review of access standards. Shortcomings in assessing productivity are detailed in the Assessment G report.

We found that VA faces a number of barriers in planning for and using its fiscal resources effectively. The main issues identified in the VA budget process include concerns about the data used for budget planning and inflexibility in budgeting stemming from congressional appropriation processes. VHA develops its budget from older data using models that project past utilization and trends into the future. If access barriers curtail demand, past utilization will underestimate the resources required to provide access. If past trends are a poor predictor of future trends, budget requests will be too high or too low. As we discuss elsewhere in this report, VA does not have sufficient data to accurately identify unmet demand, and we were not able to evaluate EHCPM prediction accuracy over time. As discussed earlier and in the Assessment A report, however, it is possible that demand will level off in the coming years. If it does, this should facilitate budget projection.

Congressional priorities can affect VA's appropriation, as with the enactment of the Veterans Choice Act. The impact of increases in purchased care from the Veterans Choice Act on the budget in future years is currently unknown. The additional providers hired with Veterans Choice Act funds will also need to be accounted for in the next budget cycle.

The allocation of the funds to VISNs for medical services is based on a quantitative model designed to capture the local cost of service, the severity of patients, and the overall workload of a facility. This process is generally thought to be equitable. However, we found that it is using data that are several years behind the current allocation year. Unless VA and the VISNs closely monitor utilization and spending trends during the execution year and reallocate funding as needed, reliance on two-year-old data can leave facilities that are experiencing strong demographic trends over- or underfunded in the current year, and creates incentives for facilities to see more of certain types of patients in order to increase funding in future years.

Interviewees indicated that the separate IT and facility budgets are insufficiently linked to medical service funding and are detrimental to their ability to respond quickly to the need to

---

expand workforce at a facility. Facility directors believe that Central Office processes take too long, and facility directors lack flexibility to move money between funding streams. They also said that they lack flexibility to manage special purpose funding efficiently across their facilities.

In the next subsection, we turn from a focus on fiscal resources to consider VA's workforce and human resources capacity, that is, the employees who support and provide health care for Veterans.

3.2   Workforce and Human Resources

While VA's fiscal resources fund its health care system, VA's workforce and human resources consist of the people who support and provide health care for Veterans. VA employs physicians, nurses, and other providers directly, owning and operating hospitals and other facilities to meet eligible Veterans' needs under a fixed budget. VA also contracts with private physicians to deliver some services within VA facilities (GAO, 2013c). Additionally, as described in Subsection 3.4, under special circumstances VA will purchase care. As such, VA capacity to deliver services is affected by the capacity of both the VA and the non-VA workforce.

Understanding VA's total workforce capacity is complex due to this mix of internal and contracted services, but generally this capacity depends on two key factors:

- The number of providers, which will depend on the ability of VA to hire and retain staff at each facility
- Provider productivity, which is shaped by factors such as sufficiency of support staff, IT capabilities; VA's staff management capabilities, including culture and policy; and physical infrastructure (for example, number and size of exam rooms).

This subsection is divided into four parts. The first part describes how VA assesses and plans for the number of providers required to meet the needs of VA beneficiaries. The second part describes the numbers of clinicians providing direct patient care at VA and their productivity. The third part determines where the biggest workforce capacity constraints might exist by specialty. Finally, the fourth part discusses why workforce-related capacity constraints might exist. When comparing across specialties, we focus on 12 specialties that care for the seven illustrative clinical populations considered in Assessment B.

A summary of the methods used in these analyses is shown in the box.

> **Overview of Methods and Data for Assessment of Workforce and Human Resources**
> - To assess VA's health care workforce resources and capabilities, we developed descriptive data tables describing total workforce and productivity estimates for physicians, associate providers, and therapists, and generated reports for representative specialties, including those relevant for the illustrative clinical populations.
> - We used worked clinical FTE counts for physicians, associate providers, and therapists to describe the current workforce and work RVUs to measure specialty physician and associate provider productivity. For therapists, we measured productivity in terms of the number of encounters per therapist

clinical FTE. For primary care, we measured physician productivity by measuring "panel size," that is, the number of unique patients seen by each primary care physician per year.

- We assessed variation in specialty care workforce supply and productivity and the extent to which various factors might affect workforce supply through changes in the recruitment and retention of various provider types.

- We interviewed VA employees and others with VA expertise to gather information related to workforce planning, productivity, and barriers to recruiting and retaining workers. We supplemented these analyses with an extensive review of the literature.

- For each of the seven illustrative clinical populations, we selected a subset of specialties that care for patients within the population and characterized facilities based on a measure of accessibility (measure of wait times for new patients) and productivity (RVU estimates). We used the wait-time variables to categorize each facility-specialty combination as having high or low wait times and used the findings from the literature reviews and interviews to identify specialties for which there are likely capacity constraints as well as potential causes of capacity constraints.

- Data sources used in these analyses include staffing and productivity data provided by Assessment G (including data collected from the VISTA New Person File, VISTA Patient Care Encounter File, and the Monthly Program Cost Report); SK&A Office-Based Physician, Nurse Practitioner, and Physician Assistant Database; VA Planning Systems Support Group Enrollee file; MGMA surveys; and VSSC [See Strategic Analytics for Improvement and Learning Cube]

- For complete details of the methods used to assess workforce and human resources, please refer to Section 2 of this report.

This subsection will not discuss most indirect factors associated with provider capacity as they are discussed in other parts of this report or in other assessments:

- Assessment A addresses the demand for services.

- Subsection 3.4 of this report and Assessment C discuss purchased care.

- Subsection 3.3 of this report and Assessment K examine the space and medical supply inputs that can influence the number of providers available.

- Subsection 3.5 of this report discusses in greater detail the IT initiatives that may affect provider productivity.

- Assessment G constructs provider productivity measures and FTE counts, benchmarking them against private-sector productivity.

In addition, there is nontrivial overlap between work performed by Assessments B and G in terms of VA workforce. Both Assessments B and G use VA data to estimate provider counts and productivity for physicians and associate providers in the VA system. Assessment G processed and made these data available to Assessment B. Assessment B combines these data with wait-

time and interview data to identify the specialties with capacity constraints and factors affecting capacity in order to describe potential capacity constraints of those physicians. Assessment B also develops estimates of provider counts and productivity for therapists (for example, physical therapists and occupational therapists).

Despite the significant overlap between Assessments B and G, there are important differences in the approach to estimating provider FTE counts. In order to calculate total FTE counts, Assessment B focused on the worked FTEs, whereas Assessment G focused on paid FTEs, which includes worked FTEs plus additional labor mapping categories, most notably leave. We felt it was most appropriate for Assessment B to focus explicitly on the amount of time providers spent working (that is, worked FTEs). We believe that this is a closer reflection of the amount of resources available to provide timely, accessible care for Veterans. Differences in the FTE definitions have the most significant effect on estimates of the total number of providers as well as estimates of the proportion of time that providers spend performing clinical duties.

3.2.1   Assessing and Planning for Workforce Capacity

In this subsection, we discuss how VA assesses and plans for the number of providers required to meet the needs of VA beneficiaries. These processes lay the foundation for VA's workforce capacity. It is important to understand how these processes work and what their strengths and weaknesses are. This subsection also includes a brief discussion of how VA measures provider productivity and whether deficiencies exist in this process. We also discuss improvements to productivity measurements and workforce planning that were developed as part of the 2014 VA Interim Workforce and Succession Strategic Plan.

3.2.1.1   VA Approaches to Assessing and Planning for the Health Care Workforce

To determine the optimal number of health care providers in each facility, VA uses several tools to measure the workload and productivity of providers and the timeliness and quality of care they deliver. Generally, these reports are accessed by both facility and VISN leadership, but facility leadership are generally responsible for assessing staffing levels and taking personnel actions.

- **Primary care workload.** To measure the workload or productivity of primary care physicians, VA staffing models use a panel size method, which sets limits on the number of services a provider can deliver and the number of patients for which the provider can be accountable. The VA definition of a patient panel differs meaningfully from non-VA definitions. VA defines a panel as the number of patients that have visited a VA primary care provider within a defined time period (for example, 12 months for new patients and 24 months for established patients). Conversely, most non-VA providers define panels as all patients for which a provider is responsible regardless of the timing of their most recent visit. This may have unknown effects on comparison of panel sizes within and outside of VA.

- **Specialty care workload.** For specialty care, VA recently developed a staffing model based on work RVUs—values used for determining the relative time and intensity required to deliver a given service. RVUs are designed to determine physician payment in Medicare

and are used by most other payers. RVUs consist of a facility portion and a work portion. Our RVUs focus exclusively on the "work" portion of the RVU. A service with a higher work RVU is one that requires more time or more intensity work by a provider. VA differs from non-VA health care systems in the way they use productivity metrics. Outside of VA, productivity measures are often not used at all. When they are used, they are not typically used for workforce capacity planning.

- **Facility-level productivity.** Facility-level productivity estimates are calculated as the sum of the work RVUs divided by the number of physicians working at that facility. Facility-level RVUs are calculated separately for each facility by specialty. VA uses these values to estimate the number of providers needed to care for its projected specialty care patient population.

Determining primary care capacity. VA uses the Primary Care Management Module to assign each patient to a primary care team composed of one primary care provider and various support positions. To determine primary care team capacity, VA sets panel size expectations based on the number of active patients assigned to each primary care provider. Panel size expectations vary depending on levels of support staff, space, and patient complexity. Some facilities are also experimenting with linking factors such as patient experiences or outcomes to their estimates of needed staffing levels (Griffin & Swan, 2006). At a June 2014 House subcommittee hearing, Dr. Thomas Lynch, the Assistant Deputy for Clinical Operations and Management of VA, mentioned that VA may start using RVU-based approaches to assess productivity, efficiency, staffing, and capacity for primary care services, but details were not discussed at length in the documents we identified (House Committee on Veterans Affairs, 2014).

Determining specialty care capacity. The Office of Productivity, Efficiency, and Staffing produces productivity benchmark data for specialty care providers based on the distribution of productivity estimates within VA, given that little national guidance exists for most specialties. The source of the data is the Physician Productivity Cube (PPC), a unique national data set that houses VA specialist workforce, workload, and productivity data from various Corporate Data Warehouse databases. Like many private-sector health care organizations, VA measures specialty care productivity in the PPC as work RVUs (VHA, 2014), supplemented by information on the number of encounters and the number of patients. VA then created the Specialty Productivity Access Report and Quadrant Tool (SPARQ), which uses PPC data to generate user-friendly, summative reporting for VA facilities to review facility or specialty-specific productivity and wait-time data. This report allows VA and facility leadership to identify where a facility's wait times are long compared with other VA facilities and to understand the extent to which long wait times might be driven by low productivity relative to other facilities. SPARQ can be used to generate reports using PPC data to assist VA and facility leadership in evaluating specialty productivity, access, staffing, and efficiency (OPES, 2014).

One interview respondent described how the PPC helped them identify ways to improve productivity:

> So [the PPC] is a tool that everybody uses across VA, and we use it extensively here. What we're finding is that there are far too many people that are doing administrative

work that probably should be doing more clinical work. So we have been slowly but surely relentlessly cracking down on that.

Most facility leaders we interviewed described workforce planning as an iterative process; they rely on sister facilities and other comparative benchmarks to determine staffing levels, while also keeping apprised of access measures—primarily wait times—to ensure that staffing is adequate for demand in each specialty. However, they reported that they use the wait-time and productivity data available in the PPC and SPARQ and are interested in further refinements to the data (see below). Respondents cited these analyses of provider workload and related assessments of provider capacity as key inputs when facilities try to identify causes of poor access in certain specialties: "If we're struggling to get patients seen, then we're looking at all of the possibilities: Are there things we can do to make them more efficient? Is there a way to schedule additional clinics using either fee or part-time?"

VA has improved its tools for tracking productivity and workload over the past decade. VA relies heavily on the PPC to track provider workload and productivity and has used this data repository to develop user-friendly summative tools for facilities to review practice performance. RVU-based productivity measures have become the standard for specialty physicians. Discussions regarding its use for measuring primary care productivity are currently taking place, and it will likely become a VA physician-wide method in the future. Steps to advance the effective use of these data in staffing and workload decision making will likely occupy VA for the foreseeable future.

3.2.1.2 Challenges VA Faces in Planning for and Assessing the Health Care Workforce

We identified several key challenges associated with VA staff planning and assessment processes. These include a lack of guidance about what methods should be used, a lack of external productivity benchmarks, inaccurate or incomplete data inputs, and the inability of the data system to adequately account for certain types of providers and patient visits.

The VA Office of Inspector General determined in 2012 that VA facilities often do not have staffing plans because of unclear direction on which methodologies to use to identify occupations that are experiencing shortages (VA, Office of Inspector General, 2012a). In 2015, the VA Office of Inspector General also found that the methods to identify staffing shortages are not adequate because they are based on VA regional rankings, which do not have enough detail at the facility level to help facility leadership set staffing targets (VA, Office of Inspector General, 2015a).

The 2012 VA Office of the Inspector General report also highlighted the fact that many specialties do not have productivity standards—an issue that both the VA Office of the Inspector General and the GAO have repeatedly pointed out over the past two decades (GAO, 1997b; House Committee on Veteran' Affairs, 2013; VA, Office of Inspector General, 2012a). VA continues to work on this important issue. The PPC allows hospitals and health care systems to compare themselves against national medians, medical centers of similar size and complexity, and private-sector benchmarks. However, most studies that compare VA with the private sector highlight the fact that significant variation in patient populations, modes of care delivery, and

payment structures make a clean comparison difficult (Asch et al., 2004; Yaisawarng & Burgess, 2006). Assessment G addresses this issue in detail.

The accuracy of some data inputs into the staff planning process can be problematic. In particular, interviewees reported that variations in Current Procedural Terminology coding practices, inconsistently entered workload data, and incomplete or poorly detailed physician encounter data make it difficult to consistently measure productivity. Some interviewees expressed concern that RVU-based workloads do not capture the full spectrum of services provided because individual procedures and other services are not as reliably coded as bills generated in a fee-for-service system. As a consequence, the differences in RVUs between providers or facilities could reflect differences in coding practices rather than true differences in productivity. In addition, with an integrated delivery system, services and costs for services are not measured in individual units, making calculations of RVUs and comparisons to the private sector difficult. Some interview respondents noted issues with the accuracy of the labor-mapping data: "We're finding that . . . some people have been credited for doing things that they really shouldn't get credit for doing in terms of admin time, education time, and so forth."

The current data systems do not adequately account for certain types of providers in the staff planning process. Internal VA documentation highlighted several issues with data tracking that continue to be a problem (VHA, Office of Productivity, Efficiency, and Staffing, 2014b). For example, providers working for VA under contract are not directly counted in the FTEs for specialty care because the system includes only data for VA-salaried physicians. VA facilities can expand their workforce by using part-time providers acquired via contracts between VA and its affiliates (contracts), or via relationships with independent providers that work at VA for a fee (fee-basis). Contract providers have appointments at facilities with formal VA affiliations, such as medical schools. Fee-basis providers accept a temporary, intermittent, or part-time appointment for a fee, but they are not necessarily linked to a VA affiliate. Contracted and fee-based providers are unique from purchased care in that they work within the walls of VA.

Given that there is no data source available for the FTE value for in-house fee or contract physicians, the PPC does not calculate a direct productivity measurement for contracted physicians. Another issue is that the system does not provide specialty specificity for advanced practice providers, so encounters that have only a nurse practitioner or physician assistant listed cannot be easily mapped to specialties in the PPC. Additionally, medical residents are not distinguished from fully qualified physicians in practice productivity measures and are not included in specialty-specific counts, which may artificially lower productivity measures by specialty grouping. Perceived problems with productivity assessments have led some facilities to implement policies to improve the usefulness and accuracy of these data, including establishing procedures for comparing labor-mapping data to providers' scheduling grids. However, these procedures are labor-intensive and not widely implemented.

The data systems also are not able to fully account for certain types of visits. Interview respondents described how new initiatives such as telehealth and group clinics have strained the utility of these metrics:

> We have group visits that allow us to treat eight or 10 patients in a group setting, and if
> the wrong code is being used in the group setting, sometimes we don't get the workload

---

credit, and it looks like it might be a productivity issue whereas, in fact, the provider is
working very hard, is very productive; he's just not getting credit.

Despite progress in productivity and workload measurement, there are still a handful of
challenges VA needs to overcome to ensure that the data and tools it uses to plan and assess
the health care workforce are more valid and reliable. In addition to standardizing staff level
and productivity targets, VA is still refining the micro-level data that feed into its data systems.
Steps to address these accuracy issues have been taken, but adjustments to the way clinical and
administrative data are collected and classified are needed to improve upon existing systems.

3.2.2 Current VA Health Care Workforce Resources and Capabilities

Current VA capacity is a function of the number of providers in the VA workforce and their
productivity. This subsection provides an overview of the current (FY 2014) VA staffing numbers
and productivity data. One of the largest providers of health services in the world, VA had
nearly 300,000 employees in 2014 (Healthcare Talent Management, Workforce Management &
Consulting Office, & Veterans Health Administration, 2014). While VA's workforce grew 15.8
percent from 2008 to 2012, the growth rate slowed over that period. In this subsection, we
describe the numbers of clinicians providing direct patient care at VA and their productivity.
Although many types of employees provide VA patient care, because of limitations in the data
available to us, we focus on clinical providers, such as physicians; associate providers, such as
nurse practitioners and physician assistants; and therapists, such as physical and occupational
therapists. In other parts of this report, we will discuss issues involving other employees (for
example, registered nurses and support) that might affect the numbers and productivity of the
billing providers and therapists. Throughout this discussion, we use the "facility" as the unit of
analysis. We consider a facility to include an administrative parent facility, often a VAMC, and
its associated outpatient clinics (for example, CBOCs).

3.2.2.1 Workforce Numbers

Physicians spend their time in various ways, including providing clinical care, conducting
research, performing administrative tasks, and teaching. As a result, the number of physicians
employed by VA may overstate the level of resources allocated to patient care. Therefore, we
focus on the number of clinical FTEs: If a physician works full-time for VA but only half in clinical
care, he or she contributes 0.50 clinical FTEs. Clinical FTEs also include clinical activities outside
face-to-face patient appointments, but do not include other labor mapping categories, such as
paid leave. In FY 2014, VA employed a total of 31,269 physician[17] employees working either full-
time or part-time, for a total of 19,900 FTEs. On average, these physicians spend close to 80
percent of their FTEs in clinical care, for a total of 15,543 physician clinical FTEs across all
specialties. On average, there were approximately 121 physician clinical FTEs per parent facility.

---

[17] Consistent with VA methodology for designating "physicians," this category also includes a small set of
nonphysician clinicians including psychologists and chiropractors.

Physicians. Table 3.2-1 summarizes FY 2014 physician clinical FTEs and physician clinical FTEs per 1,000 unique patients for an illustrative set of specialties, focusing explicitly on 12 specialties that serve the illustrative clinical populations. The specialties with the largest FTE counts were mental health (an average of 34.2 physician clinical FTEs per facility) and internal medicine (an average of 27.94 physician clinical FTEs per facility). Other specialties were not as well represented. For example, the average physician clinical FTE per facility was 1.12 for endocrinology and 0.80 for obstetrics and gynecology.[18] The number of physician clinical FTEs in each specialty varied across facilities. The greatest variations, as measured by coefficient of variation, were for physical medicine and rehabilitation, emergency medicine, thoracic surgery, and mental health.

Table 3.2-1. VA Physician Clinical FTEs Overall and Per 1,000 Unique Patients at the Facility Level, FY 2014

Specialty	Count of Facilities	Overall Clinical FTEs —Mean (Standard Deviation)	Overall Clinical FTEs— Coefficient of Variation	Clinical FTE Per 1,000 Unique Patients at Each Facility— Mean (Standard Deviation)	Clinical FTEs Per 1,000 Unique Patients at Each Facility— Coefficient of Variation
Mental health	140	34.2 (21.36)	0.62	0.69 (0.24)	0.35
Internal medicine	140	27.94 (17.09)	0.61	0.57 (0.14)	0.25
Emergency medicine	111	4.11 (3.30)	0.80	0.08 (0.06)	0.75
Cardiology	126	3.01 (1.96)	0.66	0.06 (0.03)	0.47
Surgery	126	2.96 (1.58)	0.53	0.06 (0.03)	0.48
Gastroenterology	112	2.48 (1.57)	0.63	0.04 (0.02)	0.44
Physical medicine and rehabilitation	124	2.44 (2.11)	0.86	0.05 (0.04)	0.75

---

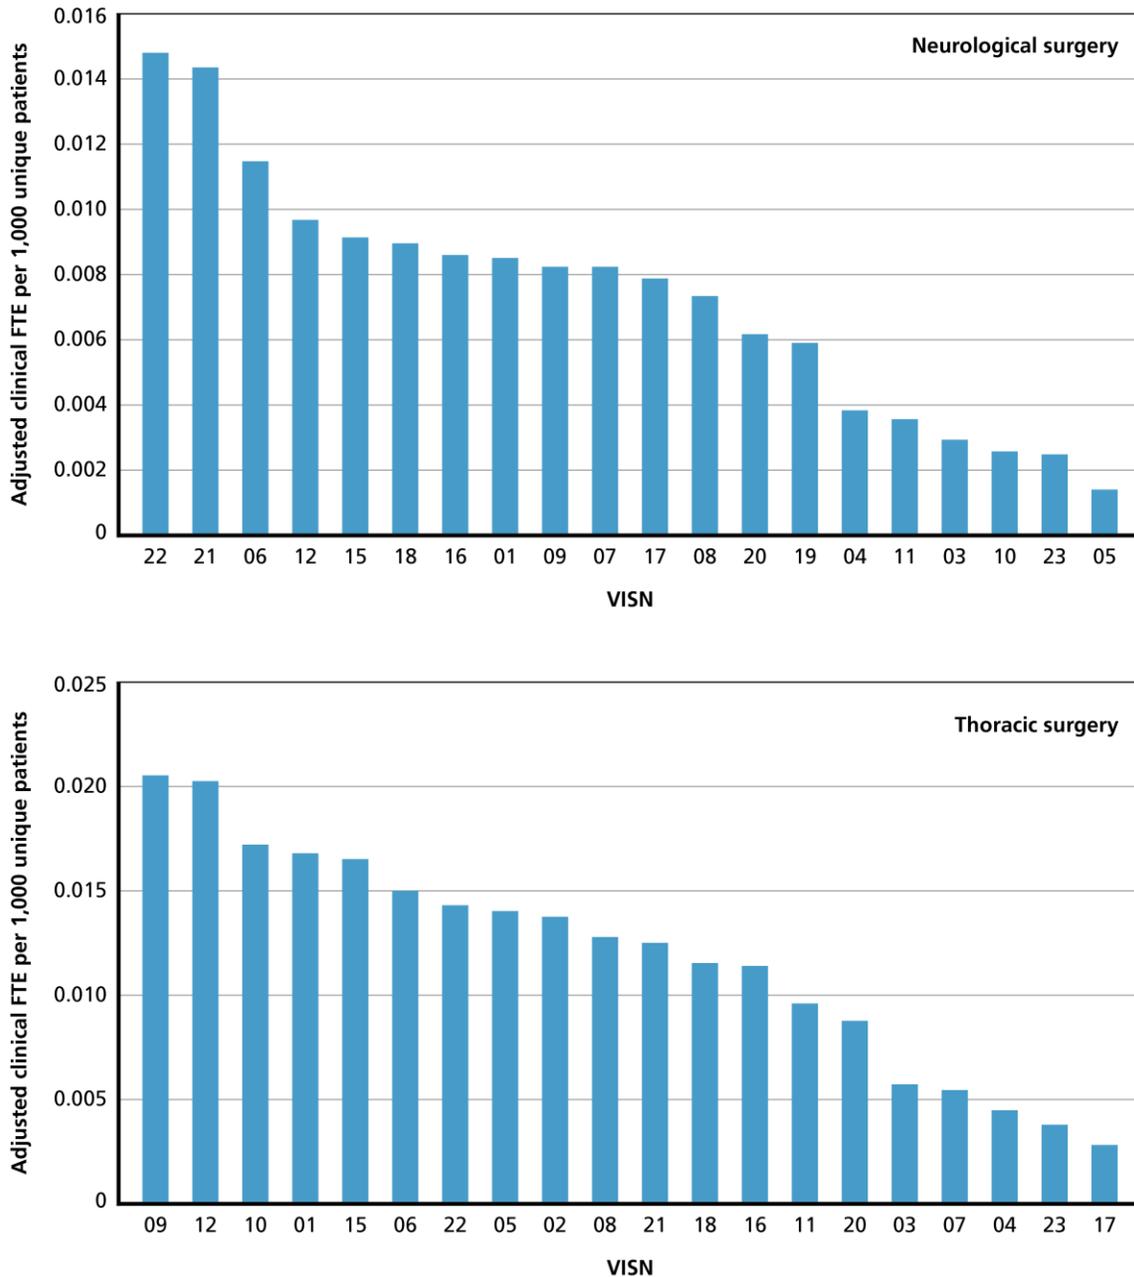
[18] Although VA does not offer obstetrical services, the related specialty is referred to as "obstetrics and gynecology" both within and outside the VA. We retained this nomenclature to be consistent with non-VA workforce analysis and internal VA documentation.

Specialty	Count of Facilities	Overall Clinical FTEs—Mean (Standard Deviation)	Overall Clinical FTEs—Coefficient of Variation	Clinical FTE Per 1,000 Unique Patients at Each Facility—Mean (Standard Deviation)	Clinical FTEs Per 1,000 Unique Patients at Each Facility—Coefficient of Variation
Neurology	126	2.25 (1.44)	0.64	0.04 (0.02)	0.52
Hematology-Oncology	105	1.94 (1.15)	0.59	0.04 (0.02)	0.44
Thoracic surgery	67	1.14 (0.85)	0.75	0.02 (0.02)	0.84
Endocrinology	99	1.12 (0.71)	0.63	0.02 (0.01)	0.59
Neurological surgery	54	0.94 (0.63)	0.67	0.02 (0.01)	0.66
Obstetrics and gynecology	81	0.8 (0.61)	0.76	0.16 (0.10)	0.64

Source: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G.

We also considered a measure that accounts for the number of patients seen in each facility: physician clinical FTEs per 1,000 unique patients who visited that facility in the past fiscal year. This measure allows for more comparable measurement across facilities, given that facilities can vary in size or number of affiliated sites, for example. In mental health, we found an average of 0.35 physician clinical FTEs per 1,000 unique patients, and, in emergency medicine, the facility average was 0.08 physician clinical FTEs per 1,000 unique patients. As expected, for most specialties, there was less variation across facilities in the number of providers per 1,000 unique patients than there was for total clinical FTEs. This likely reflects the fact that some of the variation across facilities in FTEs is explained by the size of the facility as measured by the total number of unique patients visiting that facility.

Some of this variation in FTEs per 1,000 could be explained by differences in regional practice patterns, differences in patient complexity, or differences in the use of contracted providers. For illustrative purposes, we also examined variation in the FTEs per 1,000 unique patients across VISNs. We found significantly less variation compared with the facility-level analysis. To illustrate the variation across VISNs, in Figure 3.2-1 we show the distribution for the specialties with the two highest coefficients of variation (neurological surgery and thoracic surgery). There is substantial variation in the FTEs per 1,000 patients in these two specialties. For example, for thoracic surgery, one VISN has as many as 0.02 clinical FTEs per 1,000 unique patients and another has as few as 0.001 clinical FTEs per 1,000 unique patients.

Figure 3.2-1. VA Clinical FTEs per 1,000 Unique Patients by VISN for Select Specialties, FY 2014


MS4675B-3.2-1

Source: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G.
Notes: City hubs associated with each VISN are listed in Table 3.1-3. One VISN is missing from the neurological surgery figure because that VISN does not have any clinical FTEs dedicated to that specialty.

Furthermore, to account for this variation across VISNs, we also performed regression analysis to create estimated FTE values controlling for VISN and patient complexity level at each facility.

Although we do not show these estimates, they suggest that there is still significant variation across facilities that cannot be explained by region and patient complexity.

Finally, the variation that we observe across facilities should be interpreted with caution, particularly for some of the specialties with relatively low FTE numbers. Specialties with the highest coefficients of variation tend to be those with small provider counts. For example, while thoracic surgery shows high levels of variation across VISNs, the mean FTEs per 1,000 unique patients type is only 0.02. Thus, a difference of less than 0.04 FTEs per 1,000 unique patients between the VISNs with the highest and lowest number of FTEs seems substantial, though is less so in absolute terms.

Primary care physicians work across a number of different specialties at VA. Assessment G worked with the Office of Primary Care to identify which of the 15,543 physician clinical FTEs are currently working in primary care clinics. That process yielded 3,385 primary care physician clinical FTEs. Table 3.2-2 shows the average number of primary care clinical FTEs across facilities. On average, there are 24.2 primary care physician clinical FTEs per facility or 0.62 physicians per 1,000 unique patients. We found relatively less variation across VISNs (data not shown).

Table 3.2-2. VA Primary Care Physician Clinical FTEs Overall and Per 1,000 Unique Patients at the Facility Level, FY 2014

Specialty	Overall Clinical FTEs— Mean (Standard Deviation)	Overall Clinical FTEs— Coefficient of Variation	Clinical FTEs per 1,000 Unique Patients— Mean (Standard Deviation)	Clinical FTEs per 1,000 Unique Patients— Coefficient of Variation
Primary care physicians	24.18 (15.06)	0.62	0.62 (0.16)	0.26

Source: Authors' analysis of primary care data provided by Assessment G.

Associate Providers. Associate providers (that is, nurse practitioners, physician assistants, clinical nurse specialists, certified registered nurse anesthetists, and social workers) support and supplement the work of physicians in VA. In FY 2014, VA employed 21,141 associate providers who work either full-time or part-time, for a total of 15,386 worked FTEs. Associate providers spent 94 percent of their time in clinical work, for a total of 14,441 clinical FTEs. These clinical FTEs consisted of 3,626 nurse practitioners, 1,587 physician assistants, 396 clinical nurse specialists, 598 certified registered nurse anesthetists, and 8,221 social workers. These associate providers cannot easily be mapped to a particular specialty, so we provide only the overall number per facility. In Table 3.2-3, we present information on the associate providers per physician clinical FTE. For nurse practitioner, clinical nurse specialist, and physician assistant positions, we present the clinical FTEs per all physician clinical FTEs; for social workers, we use

mental health providers; and for certified registered nurse anesthetists, we use anesthesiologists. For all other associate providers, we use all providers as the denominator. The greatest variation across facilities was seen for clinical nurse specialists, with an average of 0.023 clinical FTEs per 1,000 unique patients and a coefficient of variation of 1.13.

Table 3.2-3. VA Associate Provider Clinical FTEs Overall and Per 1,000 Unique Patients at the Facility Level, FY 2014

Specialty	Count of Facilities	Overall Clinical FTEs—Mean (Standard Deviation)	Overall Clinical FTEs—Coefficient of Variation	Clinical FTEs Per 1,000 Unique Patients at Each Facility—Mean (Standard Deviation)	Clinical FTEs Per 1,000 Unique Patients at Each Facility—Coefficient of Variation
Social worker	140	26.95 (25.64)	0.95	0.57 (0.45)	0.80
Nurse anesthetist	112	5.34 (3.97)	0.74	0.098 (0.055)	0.56
Physician assistant	135	4.65 (4.75)	1.02	0.097 (0.097)	1.00
Nurse practitioner	140	4.37 (5.50)	1.26	0.090 (0.099)	1.11
Clinical nurse specialist	116	1.21 (1.43)	1.18	0.023 (0.026)	1.13

Data sources: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G.

Assessment G also identified which of the associate providers work in primary care. That process yielded 1,188 primary care NP clinical FTEs and 330 primary care PA clinical FTEs. Table 3.2-4 shows the average number of primary care associate provider clinical FTEs across facilities.

Table 3.2-4. VA Primary Care Associate Provider Clinical FTEs Overall and Per 1,000 Unique Patients at the Facility Level, FY 2014

Specialty	Count of Facilities	Overall Clinical FTEs—Mean (Standard Deviation)	Overall Clinical FTEs—Coefficient of Variation	Clinical FTEs Per 1,000 Unique Patients at Each Facility—Mean (Standard Deviation)	Clinical FTEs Per 1,000 Unique Patients at Each Facility—Coefficient of Variation
Nurse practitioner	139	8.54 (5.42)	0.63	0.25 (0.14)	0.56
Physician assistant	103	3.2 (2.83)	0.88	0.09 (0.08)	0.88

Data sources: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G.

Therapists. Therapists also play a key role in caring for Veterans. In FY 2014, VA employed 5,615 FTE therapists, who spent 95 percent of their time in clinical work, for a total of 5,339 clinical FTEs. These clinical FTEs consisted of 1,793 physical therapists, 1,000 occupational therapists, 1,007 audiologists, 698 recreational therapists, 257 kinesiotherapists, 331 blind rehabilitation therapists, and 305 speech language pathology therapists. Table 3.2-5 presents the mean number of clinical FTEs across facilities by type of therapist. Physical therapists account for the largest number of clinical FTEs, on average, compared with the other therapist groups.

Table 3.2-5. VA Therapist Clinical FTEs Overall at the Facility Level and Per 1,000 Unique Facility Patients, FY 2014

Specialty	Overall Clinical FTEs—Mean (Standard Deviation)	Overall Clinical FTEs—Coefficient of Variation	Clinical FTEs Per 1,000 Unique Patients—Mean (Standard Deviation)	Clinical FTEs Per 1,000 Unique Patients—Coefficient of Variation
Physical therapy	12.33 (7.83)	0.64	0.26 (0.11)	0.42

Specialty	Overall Clinical FTEs— Mean (Standard Deviation)	Overall Clinical FTEs— Coefficient of Variation	Clinical FTEs Per 1,000 Unique Patients— Mean (Standard Deviation)	Clinical FTEs Per 1,000 Unique Patients— Coefficient of Variation
Occupational therapy	7.28 (5.80)	0.80	0.15 (0.09)	0.60
Audiology	7.25 (4.50)	0.062	0.15 (0.05)	0.33
Recreation therapy	5.28 (4.68)	0.89	0.12 (0.12)	1.00
Kinesiotherapy	3.74 (3.82)	1.02	0.08 (0.07)	0.88
Blind rehabilitation	3.12 (4.58)	1.47	0.06 (0.08)	1.33
Speech language therapy	2.36 (1.83)	0.78	0.05 (0.03)	0.60
Overall	37.86 (24.98)	0.66	0.78 (0.34)	0.43

Source: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G.

3.2.2.2 Workforce Productivity

In these analyses, specialty physician productivity is defined as work RVUs per physician clinical FTE. Work RVUs assigned to a particular procedure or office visit reflect the relative level of time, skill, training, and intensity needed to provide that service. Higher RVU work takes more time, more intensity, or both. Because of the way work RVUs are constructed, they are best used to compare productivity within specialties rather than across them. For primary care

services, VA productivity is measured using panel sizes. For therapists, productivity is measured as the number of encounters in a fiscal year. All of these are measured per clinical FTE. Assessment G examines physician productivity in detail and compares VA physician productivity to commercial benchmarks.

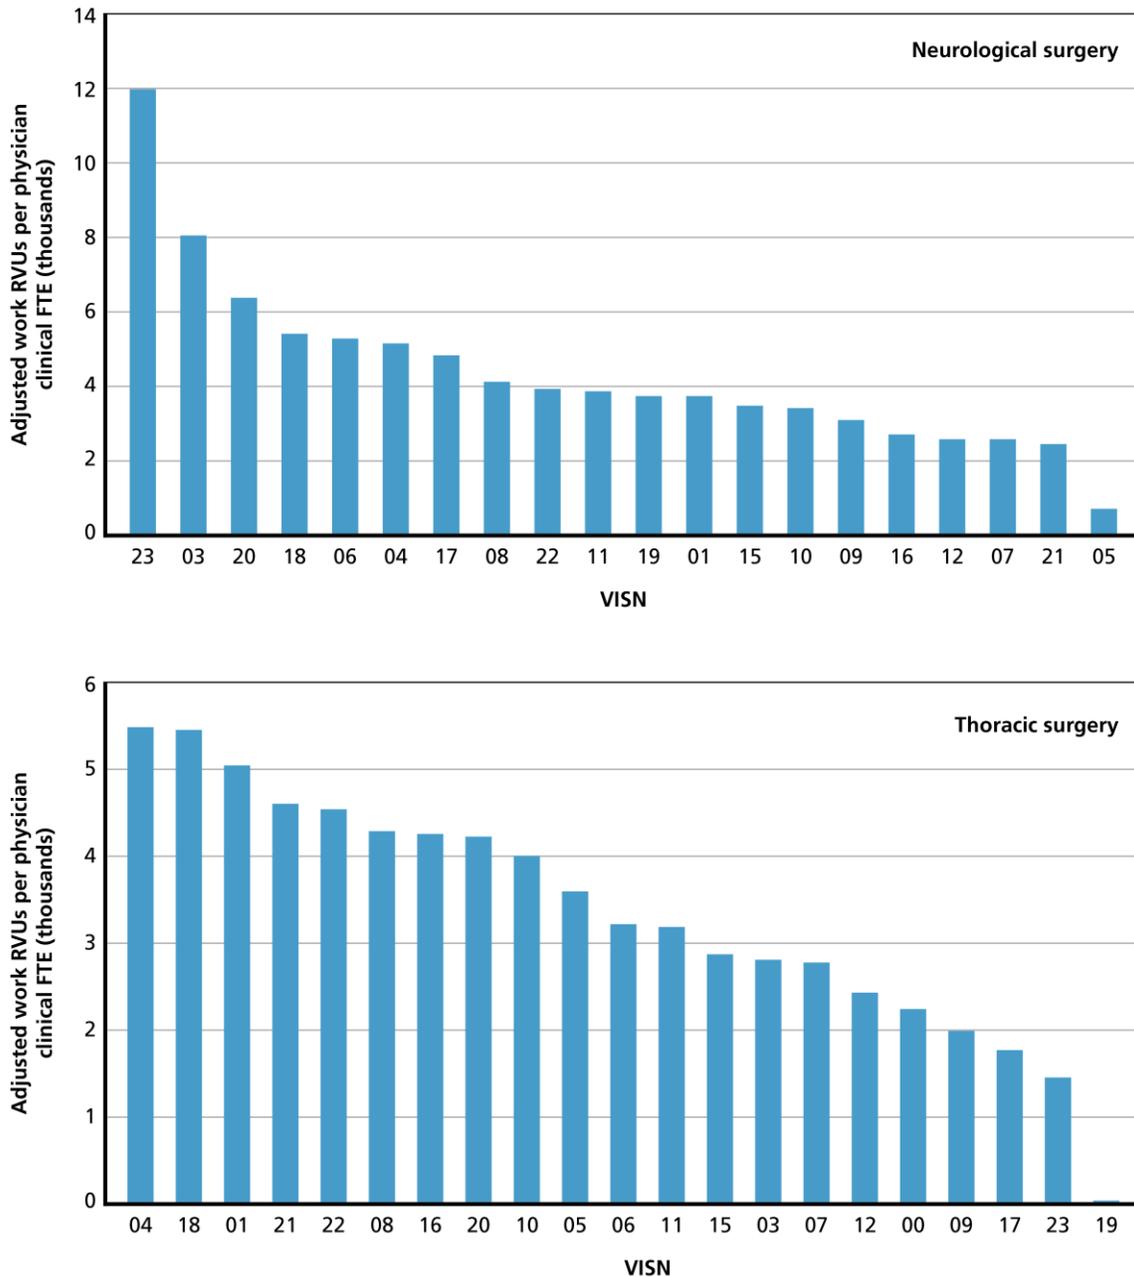
Specialty Care. The greatest variations in physician productivity were in neurosurgery and thoracic surgery, while the smallest variations were in internal medicine, neurology, mental health, and surgery (Table 3.2-6).

Table 3.2-6. VA Work RVUs Per Physician Clinical FTE for Select Specialties at the Facility Level, FY 2014

Specialty	Count of Facilities	Work RVUs— Mean (Standard Deviation)	Work RVUs— Coefficient of Variation
Gastroenterology	112	7,348 (3,414)	0.46
Cardiology	126	5,887 (2,379)	0.40
Neurological surgery	54	5,290 (11,116)	2.10
Surgery	126	3,874 (1,321)	0.34
Thoracic surgery	67	3,561 (2,781)	0.78
Hematology-Oncology	105	3,560 (1,531)	0.43
Emergency medicine	111	3,531 (1,552)	0.44
Endocrinology	99	3,496 (1,616)	0.46
Neurology	126	3,487 (1,161)	0.33
Physical medicine and rehabilitation	124	2,828 (1,230)	0.44
Obstetrics and gynecology	81	2,800 (1,314)	0.47
Internal medicine	140	2,768 (431)	0.16
Mental health	140	2,666 (498)	0.19

Source: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports.

Some of this variation in productivity could be explained by differences in regional practice patterns or differences in patient complexity. To examine this, we also examined variation across VISN by physician specialty. In general, we found less variation in physician specialist productivity by VISN than by facility. However, there was still substantial variation across VISNs. Figure 3.2-2 shows the distribution of productivity per FTE for the two physician specialties with the largest variation (that is, neurological surgery and thoracic surgery). For example, for neurological surgery, one VISN has as many as 5,471 RVUs per FTE and another has as few as 38 RVUs per FTE.

Figure 3.2-2. VA Work RVUs Per Physician for Select Specialties at the VISN Level, FY 2014


Source: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G.

Notes: City hubs associated with each VISN are listed in Table 3.1-3. One VISN is missing from the neurological surgery figure because that VISN does not have any clinical FTEs dedicated to that specialty.

To further examine variation in productivity, we used regression analysis (as we did in the provider count estimates) to create estimated productivity values controlling for VISN and

patient complexity level at each facility. Although we do not show these estimates, they suggest that there is still significant variation across facilities that cannot be explained by region and patient complexity.

There is also significant variation in the productivity of associate providers across facilities. Table 3.2-7 shows that nurse anesthetists and clinical nurse specialists have the highest level of variation across facilities.[19]

Table 3.2-7. VA Work RVUs Per Associate Provider at the Facility Level, FY 2014

Specialty	Count of Facilities	Work RVUs—Mean (Standard Deviation)	Work RVUs— Coefficient of Variation
Physician assistant	135	1,913 (1,539)	0.80
Nurse practitioner	140	1,833 (1,511)	0.82
Clinical nurse specialist	116	1,746 (1,719)	0.98
Social worker	140	893 (544)	0.61
Nurse anesthetist	112	413 (995)	2.41

Contracted Providers. Most VA facility leaders we interviewed used either fee-basis or contract providers to some extent, based largely on the demand for services and the accessibility of specialty care. In many locations, the demand for certain services was too low to justify hiring full-time staff: "We have quite a few [fee-basis physicians], particularly in surgery because we can pay them higher and they're intermittent, and it doesn't make sense to hire a full-time person." Most VAMCs were affiliated with university medical centers and relied on these facilities to provide a pool of contract and fee-based providers to supplement full-time VA staff. Interview respondents identified emergency department physicians, hospitalists, and surgeons as the specialties most often filled with contract or fee-based providers.

Table 3.2-8 reflects the percentage of all work RVUs (VA, contract, residents, and other employees) attributed to fee-basis and other (providers without a labor mapping) physicians

---

[19] Clinical nurse specialists are doctoral- or masters- prepared advanced practice registered nurses who function in a variety of capacities, such as quality improvement, nursing education, and diagnosis and treatment of specific patient population.

and associate providers across facilities that use contracted physicians. Overall, fee-basis and other providers account for about 10.7 percent of total work RVUs. Fee-basis and other specialist physicians and associate providers account for 12.5 percent and 6.2 percent, respectively, across all specialties. Emergency medicine has the highest proportion of RVUs attributed to contract physicians (29.68 percent), while physician assistants account for the highest proportion among associate providers (8.56 percent).

Table 3.2-8. Percentage of Total Work RVUs Attributed to Fee-Basis and Other Physicians and Associate Providers at the Facility Level, FY 2014

Specialty	Count of Facilities	% of Total Work RVUs
Emergency Medicine	123	29.68
Neurological Surgery	69	28.66
Thoracic Surgery	85	28.46
Gastroenterology	122	12.23
Obstetrics & Gynecology	104	11.52

However, many interview respondents described challenges with using fee-basis and contract providers. Most respondents preferred to hire full-time staff, primarily for accountability and stability reasons. Some described significant disadvantages to using contract providers compared with fee-basis or full-time providers, including the cost per FTE, the time required to negotiate contracts, and the degree of accountability: "Even though you can put items in a

contract that you hold people accountable to, they're not as accountable as people who actually work for you and are long term and are devoted to [the facility] and its Veterans." For these reasons, most respondents preferred to use fee-basis providers to fill in gaps. Other perceived advantages of fee-basis providers included flexibility, lower cost per FTE, and higher productivity: "Fee is more of a productivity model. So folks tend to be productive if they're working in a fee arrangement versus a salaried arrangement."

Primary Care. We examined the productivity of primary care providers by examining the mean panel sizes per clinical FTE within each parent facility for general primary care (Table 3.2-9). In 2014, the mean panel size was 1,128 patients per physician FTE and 874 patients per associate provider FTE, with moderate variation across facilities.

As mentioned in Section 3.2.1.1, VA uses the Primary Care Management Module to model panel size expectations per provider FTE at the facility level, adjusting for levels of support staff, space, and patient complexity. VA facilities can further adjust the models to set their own maximum panel sizes for their providers based upon local factors and using the guidance in the PCMM handbook. For example, a facility may set a lower maximum panel size for a new provider or for a provider serving a population with special needs.

We compared the actual mean panel sizes at each facility to the modeled and maximum panel size targets for each facility to identify facilities that appear to have "excess" capacity.[20] We identified a facility as having "excess capacity" if its panel sizes were less than their modeled or maximum panel sizes. We found that 75-91 percent of all facilities had excess capacity among their physicians' panels to manage more primary care patients, whereas between 67-72 percent of facilities had excess capacity among their associate providers' panels.

Table 3.2-9. VA Panel Size Per Primary Care Provider Clinical FTE, September 30, 2014

	Average Panel Sizes Per Clinical FTE—Mean (Standard Deviation)			Proportion of All Facilities with Excess Capacity Based on:	
	Actual Panel Size	Modeled Panel Size	Maximum Panel Size	Modeled Panel Size	Maximum Panel Size
Physicians	1,128 (165.8)	1,306 (71.8)	1,207 (161.8)	90.6%	75.0%
Associate providers	874 (197.2)	982 (62.3)	940 (194.4)	71.8%	66.9%

---

[20] Memphis (TN) VAMC and its associated clinics are currently piloting a new version of the Office of Primary Care's Primary Care Management Module. As a result of the ongoing pilot, data from these sites was unavailable and is therefore excluded from our analysis.

The fact that a large proportion of facilities have "excess capacity" in their primary care panel might be interpreted in three potentially contradictory ways. First, these findings might suggest that VA facilities have more than sufficient numbers of primary care providers to provide required primary care for VA patients. Second, this data may also suggest that significant productivity constraints limit the number of patients facilities can manage in their panels, meaning that they are unable to meet their panel size targets. Third, it is possible that the VA algorithm for assessing panel sizes overestimates the number of patients that primary care providers can manage. Findings from the 2015 Survey of VA Resources and Capabilities and qualitative interviews provide some insight into this issue (discussed in more detail below). Survey data shows that VA facility representatives view primary care physicians as some of the most difficult providers to recruit and retain in VA facilities. The qualitative interviews indicate that primary care providers' have difficulty seeing as many patients as staffing models would expect due to issues with information technology and support staff. Altogether, the data suggests that there are likely capacity constraints among primary care providers, but the data cannot provide conclusive evidence regarding the nature and scope of the constraints.

Therapists. Finally, we also examined variation in productivity among therapists across administrative parent facilities. We found substantial variation across facilities in the number of annual encounters per therapist (Table 3.2-10). The most variation across parent facilities was in recreation therapy, kinesiotherapy, and blind rehabilitation therapy. The number of encounters per therapist, however, does not account for the intensity of the encounters or the case mix at the facility, which may differ systematically across types of therapy. Therefore, comparisons within a particular category are more useful than comparisons across types for understanding differences in productivity.

Table 3.2-10. VA Encounters Per Therapist Clinical FTE at the Facility Level, FY 2014

Specialty	Mean (Standard Deviation)	Coefficient of Variation
Recreation therapy	2,136 (1,736)	0.81
Audiology	2,000 (598)	0.30
Kinesiotherapy	1,811 (1,232)	0.68
Physical therapy	1,631 (448)	0.27
Occupational therapy	1,420 (554)	0.39
Speech language therapy	1,191 (372)	0.31

Specialty	Mean (Standard Deviation)	Coefficient of Variation
Blind rehabilitation	850 (433)	0.51

Subsection Summary. In this subsection, we described current numbers (as of FY 2014) of key provider types currently working in the VA system by total numbers of provider clinical FTEs as well as the number of clinical FTEs per 1,000 patients at a facility. We also described the relative productivity of various provider types. We found significant variation across facilities and VISNs in terms of provider counts and productivity. The greatest variations in physician productivity were in neurosurgery and thoracic surgery, while the smallest variations were in internal medicine, neurology, mental health, and surgery.

3.2.3 Specialties with Potentially Insufficient Workforce Capabilities

In this subsection, we attempt to identify specialties for which the current workforce capabilities have had the greatest challenges providing timely care to patients. To do this, we first present results from an analysis of wait-time data by specialty, as longer wait times could potentially signal insufficient workforce capabilities. We then present related findings from the literature review and interviews. In Subsection 3.2.4, we attempt to identify workforce-related challenges to providing timely care within specialties that have potentially insufficient capabilities.

3.2.3.1 Wait-Time Data by Specialty

We first analyzed VA wait-time data to identify the specialties with the longest wait times among the 12 specialties discussed in Subsection 3.2.2, comparing wait times across all these specialties. To measure wait times, we used four specific measures, including the percentage of appointments completed within 30 days of preferred date and the mean wait time in days from preferred date, measured both for new and established patients. The data were collected from the VA SPARQ tool. We found that wait times were longest for neurological surgery, neurology, gastroenterology, and physical medicine and rehabilitation (Table 3.2-11).

Table 3.2-11. VA Wait Times for New and Established Patients by Specialty at the Facility Level, FY 2014

Specialty	New Patients—% of Appointments Completed Within 30 Days of Preferred Date	New Patients—Mean (Standard Deviation) Wait Time in Days from Preferred Date	Established Patients—% of Appointments Completed Within 30 Days of Preferred Date	Established Patients—Mean (Standard Deviation) Wait Time in Days from Preferred Date
Neurological surgery	90.0	8.73 (11.36)	96.2	5.78 (9.44)
Neurology	92.4	7.06 (6.93)	94.9	5.41 (4.91)
Gastroenterology	92.3	6.61 (9.82)	95.5	4.82 (5.94)
Physical medicine and rehabilitation	94.1	6.47 (7.07)	96.6	3.81 (3.06)
Internal medicine	92.9	4.95 (6.29)	97.8	2.60 (2.01)
Endocrinology	96.1	4.25 (5.73)	96.6	3.72 (3.58)
Surgery	96.9	4.25 (3.56)	98.7	2.68 (2.07)
Obstetrics and gynecology	96.4	4.06 (3.79)	97.6	2.82 (2.30)
Cardiology	96.8	2.86 (3.78)	97.0	3.59 (7.73)
Hematology-Oncology	99.0	2.11 (3.77)	99.2	1.78 (1.61)
Thoracic surgery	99.1	2.03 (2.53)	99.1	2.33 (4.63)
Mental health	98.6	1.56 (3.14)	98.8	1.12 (2.29)

Sources: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G; VA wait-time data for FY 2014 and the first half of FY 2015 obtained from VSSC by The MITRE Corporation.

We recognize that the wait-time variables are imperfect measures and that the "preferred date" may have relatively low validity and reliability. Therefore, wait times should not be viewed as a reliable estimate of the actual number of days that a patient must wait for an appointment. The VA wait-time data and standards are discussed in greater detail in Subsection 4.2.1.

Although the number of patients receiving appointments within 30 days is quite high across all specialties (that is, greater than 95 percent for established patients and greater than 90 percent for new patients), there are significant outliers across the facilities in terms of the average number of days that a patient has to wait; we have identified these differences as having high versus low wait times. We identified facilities as having high wait times for a given specialty if the average wait time for new patients for that specialty was above the 75th percentile of the

wait-time distribution. The difference in average wait times was roughly 10 days between facilities with low (2.07 days) versus high (11.67 days) wait times. In Table 3.2-12, we show that these patterns hold across specialties. All of the differences in wait times are statistically significant.

Table 3.2-12. VA Average Wait Times Across Facility-Specialty Combinations with High Versus Low Wait Times

Specialty	Low Wait Times— Number of Facilities	Low Wait Times— Mean (Standard Error) Wait Time in Days from Preferred Date for New Patients		High Wait Times— Number of Facilities	High Wait Times—Mean (Standard Error) Wait Time in Days from Preferred Date for New Patients	
Cardiology	114	2.09	(0.14)	11	9.91	(1.28)
Endocrinology	72	2.26	(0.15)	26	10.15	(0.85)
Gastroenterology	69	2.48	(0.16)	40	13.37	(1.60)
Hematology-oncology	98	1.56	(0.13)	6	8.04	(0.91)
Internal medicine	99	2.69	(0.13)	40	10.26	(0.84)
Mental health	135	1.40	(0.07)	4	6.39	(0.33)

^Only one facility had high wait times for thoracic surgery.

*Across all facility-specialty combinations.

3.2.3.2 Literature Review, Interview, and Survey Results on Specialty Workforce Capacity

The literature reviews, qualitative interviews, and 2015 Survey of VA Resources and Capabilities identified a number of specialties with potentially insufficient workforce capacity. The 2014 VA Interim Workforce and Succession Strategic Plan reported five challenging specialties related to retaining and recruiting physicians and for which demand is growing, including gastroenterology, cardiology, psychiatry, orthopedic surgery, and primary care. In the analysis of wait times, we also identified gastroenterology as a specialty with potentially insufficient workforce capabilities, and 67.3 percent of respondents to the survey reported challenges hiring and retaining gastroenterologists. We did not find high wait times for psychiatry, but respondents to the survey reported significant challenges in hiring (82.6 percent) psychiatrists. We also found relatively low wait times for cardiology, and relatively few respondents reported difficulty hiring and retaining cardiologists. The 2014 Strategic Plan noted that they also had difficulty hiring orthopedic surgeons. Although we did not include orthopedic surgery in Table 3.2-11, the specialty did have relatively high wait times (7.8 days) compared with other specialties. There are no wait times specifically attributable to the "primary care" providers that we discussed in Subsection 3.2.2, but in the 2015 Survey of VA Resources and Capabilities, 71.8 percent of the responding chiefs of staff reported difficulty recruiting or retaining primary care physicians.

In our interviews, multiple respondents identified 12 specialties and provider types with shortages: mental health, urology, orthopedic surgery, hospitalist, physical therapy, eye care (ophthalmology and optometry), audiology, ear-nose-and-throat, dermatology, vascular surgery, general surgery, and neurology. However, the number of interviews was small, so the results cannot be used to identify systematic shortages across these disciplines. We did, however, find substantial wait times in neurology data, which accords with the interviews.

In terms of the literature review, we did not identify peer-reviewed articles that discuss VA capacity constraints across all these specialties; thus, we focus our discussion on the five specialties mentioned in the 2014 Strategic Plan.

Psychiatry and/or Mental Health. This was the most commonly mentioned shortage in the interviews, with about one-third of respondents indicating a shortage at their facility. Like many other specialties, the psychiatry workforce is aging; the average psychiatrist is older than 55, and the proportion younger than 40 is declining (Scully & Wilk, 2003). Psychiatrists are in high demand, largely because of increased rates of PTSD from recent combat operations (Tanielian & Jaycox, 2008). Although PTSD is certainly contributing to an increase in demand for mental health services, VA enrollees suffer from a high rate of mental health burden. In fact, Assessment A found that approximately 50 percent of VA patients had at least one mental health diagnosis, including depression and anxiety disorders. VA mental health staffing shortages were frequently discussed in the literature (VA, Office of Inspector General, 2015a). A 2011 survey noted identified that 71 percent of mental health professionals thought that the number of mental health personnel in their VA medical center was not adequate (VA, Office of Inspector General, 2012b). Though the specialty's growth rate, which is the annual net increase in providers from the previous year, jumped from 2.4 percent in FY 2012 to nearly 7 percent the

following year (as a result of a mental health hiring initiative), psychiatry also had the second-highest loss rate in VA (8.9 percent) in FY 2013, primarily due to providers quitting (Healthcare Talent Management, Workforce Management & Consulting Office, & Veterans Health Administration, 2014).

Gastroenterology. National projections of the gastroenterologist workforce predict supply shortages and rising demand, tied largely to increased rates of colorectal cancer screening and an aging population. For example, Dall et al. (2009) predict a shortfall by 2020. The 2014 Strategic Plan noted that for VA, gastroenterology had one of the highest demand growth rates in FY 2012. Powell et al. (2009) surveyed 95 percent of VAMCs to assess how quality initiatives were affecting follow-up with patients who had positive colorectal cancer screenings. Gastroenterology capacity constraints were the most commonly cited barrier to timely follow-up (Powell et al., 2009). Similarly, a report investigating gastroenterology consult delays at the VAMC in Columbia, S.C., identified suboptimal staffing as a factor (VA, Office of Inspector General, 2013). Most gastroenterology managers and clinicians we interviewed described staffing deficiencies caused by positions not being filled, difficulty getting approval for new hires, and shortages in support staff including nurses and clerks.

Orthopedic Surgery. There is very little literature that directly examines the VA orthopedic surgery workforce, which had VA's highest total loss rate in FY 2013 at 9.9 percent (Healthcare Talent Management, Workforce Management & Consulting Office, & Veterans Health Administration, 2014). However, a 2013 GAO report that touched on the frequency of VAMCs referring patients to non-VA providers (purchased care) for orthopedic surgery services cited facility size, limitations in the recruitment of needed specialists, and lack of providers who can assist in the event of a complication during surgery (GAO, 2013c). A 2013 VA survey of 152 VAMCs found that, of the 113 that provide inpatient surgery, 96 percent (109) offered orthopedic specialty procedures (VA, 2014a). In total, 414 surgeons were VA-paid, 156 were contracted, and 199 were fee-based.

Cardiology. A 2012 VA Office of Inspector General report identified cardiology as one of 33 physician specialties with lower than expected productivity levels (VA, Office of Inspector General, 2012a). Dall et al. (2009) found, at the national level, a current shortage and predicted it would worsen over the next 20 years. The study projected greater demand for cardiology services because of an aging population and a workforce nearing retirement (43 percent are older than 55). Fye (2004) predicted a 20 percent decrease in the age-adjusted supply of cardiologists by 2020 and a likely increase in demand resulting from increased incidence and prevalence of cardiovascular disease tied to population aging and obesity (Fye, 2004). While these trends are not VA-specific, they are relevant, as VA competes for cardiologists in the national market.

Primary Care. Even though the primary care workforce is the fastest growing in VA, recent media reports and the 2014 Strategic Plan have identified primary care as having potential capacity constraints (Oppel Jr., 2014; Healthcare Talent Management, Workforce Management & Consulting Office, & Veterans Health Administration, 2014). The U.S. Health Resources and Services Administration reported on the adequacy of future primary care supply to meet demand (Health Resources and Service Administration, 2013). Nationally, the demand for

primary care services is forecasted to grow more rapidly than primary care supply, due largely to an aging and growing population and the expansion of insurance coverage following health care reform. The 2014 Strategic Plan highlights shortages in primary care physicians, driven by higher demand from a patient population that is aging and has a greater proportion of women, who tend to use more primary care services than their male counterparts.

3.2.3.3 Subsection Summary

In this subsection, we attempted to identify particular specialties that have potential capacity constraints. We found that a number of specialties likely have potential capacity constraints. Although the various data sources used suggested that there are capacity constraints across various and often divergent specialties, our data analyses suggest further that there are potential significant capacity constraints within orthopedic surgery, neurology, gastroenterology, psychiatry, and primary care.

3.2.4 Potential Causes of Capacity Constraints

Drawing on wait-time and productivity data as well as the interviews, literature review, and 2015 Survey of VA Resources and Capabilities, this subsection discusses why workforce-related capacity constraints might exist.

To better understand what is driving the differences in wait times, we compared productivity across facility-specialty combinations. If productivity values are significantly lower at facilities with high wait times, one could conclude that differences in wait times are likely driven by differences in relative productivity. Conversely, if productivity is generally equivalent across high- and low-wait-time facilities or if productivity at facilities with high wait times is significantly higher compared with facilities with low wait times, this would suggest that high wait times are likely driven by an insufficient number of providers.

In Table 3.2-13, we compared productivity estimates across facility-specialty combinations with low versus high wait times. The productivity estimates are not significantly different across the vast majority of specialties. This supports the hypothesis that differences in wait times across facilities are likely largely driven by insufficient numbers of providers, as opposed to productivity deficits across the facilities with high wait times. For the one specialty for which the productivity estimates are different (gynecology), productivity was higher for high-wait-time facilities. For one specialty (mental health), productivity was significantly lower in high-wait-time facilities, suggesting that some of the difference in wait times may be attributable to relative productivity across facilities.

Table 3.2-13. VA Average Productivity Across Facility-Specialty Combinations with High Versus Low Wait Times

Specialty	Low Wait Times—Mean RVUs (Standard Error)	High Wait Times—Mean RVUs (Standard Error)
Cardiology	6,758	6,509

Specialty	Low Wait Times—Mean RVUs (Standard Error)	High Wait Times—Mean RVUs (Standard Error)
	(967)	(841)
Endocrinology	3,550 (200)	3,369 (279)
Gastroenterology	7,522 (408)	7,206 (559)
Hematology-oncology	3,594 (157)	2,782 (297)
Internal medicine	2,794 (46)	2,700 (55)
Mental health*	2,678 (43)	2,248 (192)
Neurological surgery	3,770 (421)	8,107 (3820)
Neurology	3,499 (147)	3,549 (146)
Gynecology*	2,588 (153)	3,497 (332)
Physical medicine and rehabilitation	2,798 (156)	3,060 (170)
Surgery	3,854 (145)	3,987 (211)
Thoracic surgery^	3,634 (372)	1,407 (NA)

* Statistically significant difference at p<0.05.
^Only one facility had high wait times for thoracic surgery.
+We report Standard Errors in this table (as opposed to standard deviations), as they were used as the basis for statistical testing.

To further explore the relationship between provider counts, productivity, and wait times, we performed a regression analysis. We regressed average wait times from preferred date for new patients on productivity and clinical FTEs per 10,000 unique patients, controlling for facility

complexity and specialty. We use FTEs per 10,000 unique patients, as opposed to 1,000 unique patients, to generate coefficients that are of an interpretable magnitude. Because wait times were heavily skewed, we constructed the dependent variable as the natural logarithm of wait times. We found that FTEs per 10,000 unique patients were negatively associated with wait times. That is, an increase in the FTEs per 10,000 unique patients would be expected to be associated with a decrease in wait times. We found no statistically significant relationship between productivity and wait times. Table 3.2-14 lists the coefficient, standard error, and p-value for the two variables of interest in the regression model. According to this model, a one-unit increase in clinical FTEs per 10,000 patients is associated with an 8.77 percent decrease in average wait times for a given specialty. This suggests that, consistent with our previous hypothesis, problems with timely access seem to be associated primarily with provider counts as opposed to productivity.

Table 3.2-14. Effect of VA FTEs per 10,000 Unique Patients and Productivity on Wait Times

Variable	Coefficient	Standard Error*	P-Value
Productivity	0.0000034	0.0000045	0.459
Clinical FTEs per 10,000 unique patients	−0.08768	0.024	<0.001

Source: Authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports.
Note: *Standard errors clustered by facility.

Consistent with our analysis of the wait-time and productivity data, interview respondents cited insufficient numbers of providers, driven by various challenges in hiring and retaining VA staff. Interviewees, however, also noted a number of other issues that hamper provider productivity in their facilities. We were often unable to tie these challenges to any specific specialty, so we provide an overview of these challenges more generally. Assessment G reviews the evidence on these issues in more detail.

3.2.4.1 Hiring

More than half the facilities interviewed indicated that they had insufficient funds to hire additional staff. Respondents cited "FTE caps" and funding earmarked for specific provider types that could not be used to hire others. One respondent noted that the caps do not correspond to local demand: "You have to also be able to increase your full-time equivalent to be able to address that demand. For us for several years we've been under an FTE cap, which has prevented us from being able to bring in and grow the number of people that we need."

Moreover, while staffing models and business case analyses may call for facilities to add staff, most respondents indicated that having adequate space for them to work is a challenge. Expanding space takes much longer than hiring new providers, so the problem can take years to resolve. Respondents also noted that adding physicians generates additional demand for ancillary services: "When you talk about expanding providers and talking about extra space, then you're also talking about hiring additional environmental management staff, you're talking

about extra burden on pharmacy, lab, pathology, radiology. All of those other services also have an impact."

The large majority of respondents indicated that noncompetitive salaries compared with the private sector and the proximity of university-affiliated and private facilities make it difficult to recruit VA providers. VA Central Office sets pay tiers for each job classification, specifying minimum and maximum annual salaries that facilities can offer. Respondents indicated that they struggled with recruiting providers, even at the high end of pay tiers: "When you get into dermatology, neurosurgery, those kinds of things, the top of our pay scale is sometimes at best half of what they would make in the private sector." Table 3.2-15 shows that VA salaries are indeed well below the private practice averages and are sometimes commensurate but generally lower than academic medical center practices, upward of 35 percent lower in the case of neurological surgery. Endocrinology is the only exception, with VA salaries averaging slightly higher than academic medical center salaries, though still lower than private-practice salaries.

Table 3.2-15. VA Physician Total Compensation Compared with Non-VA Physicians

Specialty	VHA Average	MGMA Private Practice Mean	MGMA Academic Practice Mean
Cardiovascular disease	$269,023	$441,777	$277,180
Emergency medicine	$225,648	$327,441	$273,045
Endocrinology	$202,594	$238,418	$180,372
Gastroenterology	$270,615	$553,574	$299,531

Source: VA analysis of VA PAID Cube, Medical Group Management Association (MGMA) Academic Survey 2014, 2013 data, MGMA Physician Compensation and Production Survey 2014 provided by Assessment G.
Note: *While VA does not have obstetrics, only combined obstetrics and gynecology metrics are available in the MGMA dataset.

Local market characteristics also contribute to staffing shortages. All respondents described challenges hiring at least one specialty—most frequently mental health, urology, orthopedic surgery, physical therapy, and hospitalists. Rural facilities experienced particular difficulties: "It's also very difficult to get specialists into small clinics because they prefer to live in the city where they have potential for income and their families want to live."

Once a job offer is made, inefficiencies in the privileging and credentialing process and bureaucratic requirements for salary negotiation make bringing providers on staff a long process: "Every time I have an open position I'm amazed by the number and the quality of the applicants that I get. But the H[uman] R[esources] process is in a state of utter paralysis." Not only does this make hiring new staff laborious, but it also means that often VA will lose otherwise interested and qualified candidates. The interview data conform to previous independent recommendations VA needed a more streamlined system for on-boarding new staff (Northern Virginia Technology Council, 2014).

Data from the 2015 Survey of VA Resources and Capabilities provide additional information about the challenges VA faces in hiring and retention. The survey asked facility leadership about difficulties in hiring and retaining particular categories of staff, related to the treatment of the illustrative clinical populations (for example, TBI, PTSD, colon cancer). In addition, chiefs of staff were asked about personnel categories that spanned multiple conditions. For those facilities reporting that there were difficulties in recruiting or retaining staff in the given category, respondents were asked about barriers to recruitment and retention. We provide descriptive statistics for the two illustrative specialties with significant reported hiring problems for physicians (that is, primary care and mental health). For primary care providers, the top two reasons for problems in recruiting were the geographic location of the facility (46.5 percent) and noncompetitive wages (47.7 percent). The top two reasons for difficulty hiring problems for psychiatrists were noncompetitive pay (60 percent) and the geographic location of the facility (36.8 percent).

3.2.4.2   Retention

Much of the literature and many of the interviews discussed issues with retaining VA employees. Although the previous subsection focused largely on physicians, this subsection also includes information about VA leadership, all staff, care teams, and providers. According to the 2014 Strategic Plan, VA lost more than 100,000 employees from 2008 to 2012, of which 47 percent resigned or were transferred and 34 percent retired (Healthcare Talent Management, Workforce Management & Consulting Office, & Veterans Health Administration, 2014), and hired a total of 164,135 employees to maintain and grow the workforce. Despite these losses, VA's annual turnover (4.3 percent in 2013) or "quit rate," which does not include voluntary retirements or external transfers, is lower than the health care industry's as a whole (16.5 percent).

Studies on VHA staffing have focused on job satisfaction and burnout as a source of retention problems (Garcia et al., 2014; Helfrich et al., 2014; Mohr, Bauer, & Penfold, 2013; Salyers et al., 2013; Teclaw & Osatuke, 2014; Weeks, Wallace, & Wallace, 2009). "Burnout" is distinct from poor job satisfaction in that it is "characterized by emotional exhaustion, depersonalization,

and a low sense of personal accomplishment." Facility leaders we interviewed similarly identified burnout as an issue, particularly in primary care. Operational issues, including technological challenges stemming from new VA initiatives, and a once advanced but increasingly outdated health IT system, were said to be causing burnout, rather than helping to relieve it.

VA processes lead to frustrations for providers, particularly related to the level of oversight and a perceived lack of resources to provide the type of care providers would prefer:

> Most docs and clinical people really want to provide excellent care, and they just get frustrated when they can't do it, when something is getting in the way of it. . . . . It's almost like on the administrative side we don't trust that the clinical folks will do the right thing. And again, that seems like an ingrained institutional impediment to success.

As with recruiting, respondents commonly cited the inability of facilities to offer competitive salaries and benefits (for example, educational debt reduction plans). This is particularly problematic in areas where geographic pay adjustments differ significantly between regions geographically close to one another:

> The second a provider or someone else like a mental health professional walks on board. . . . they're immediately looking for their next job down south where they can increase their pay and automatically get that higher geographic adjustment… so we have extremely high turnover in areas where the geographic pay is not matched out in the rest of the system.

As with the recruitment questions on the survey, we also asked a number of questions related to retention problems to supplement the interview findings. Again, we provide illustrative results for two specialties, primary care and psychiatry, for which respondents reported significant difficulty retaining providers. For primary care physicians, the top two reasons for retention problems were dissatisfaction with supervision and management support as well as dissatisfaction with workload. For psychiatrists, the top two reasons were dissatisfaction with workload (43 percent) and dissatisfaction with pay (38 percent). These were followed closely with burnout (33 percent). 40.4 percent of facilities reported that burnout was the top reason for retention problems with psychologists. The second reason was lack of opportunity for professional growth or promotion (38 percent).

3.2.4.3   Productivity

All respondents described resource constraints related to provider productivity at their facilities. They cited infrastructure issues (for example, space shortages, medical technology shortages), challenges with appointment scheduling, increased clerical tasks from new initiatives, a lack of support and clerical personnel, and cultural issues among VA providers and support staff that inhibit efficient patient care.

As described previously, most leaders we interviewed were actively trying to add space to accommodate new provider staff, as well as make existing staff more productive. Certain specialties may be more affected by infrastructure challenges due to their need for specialized

---

work spaces: "We're impacted by the number of operating rooms that are available and have to schedule around them, which sometimes can be challenging when you've got five specialties that all want to operate on the same day."

Respondents also described provider frustration with medical record alerts, scheduling system malfunctions, and scheduling mistakes that inhibit their efficiency. Most facility leaders described frustrations with VA's CPRS, including an overwhelming number of patient alerts that providers must review: "Let's say I order lab work or an X-ray on a person or a consult. . . . From the day I do it, anything else that happens to that thing, I get a view alert on it. . . . That has been driving [providers] nuts." Interviewees perceived that these challenges reduced providers' overall productivity.

Scheduling challenges were also relevant to telehealth appointments. While the availability of remote visits increase access to care for patients in remote areas, implementing technology and scheduling processes puts a strain on the host facility:

> One of the challenges with Tele visits has been that there's almost been this assumption that it in some way will either make docs more productive or overcome some of the staffing challenges. . . . There's still somebody on the other end that's having to be there for that appointment. And they often take more time than it does to do a face-to-face.

Interviews with facility leaders suggest that productivity may be negatively impacted by providers doing too many administrative or other below-license tasks: "What I hear from a lot of the individual docs is that a lot of their time is spent on 'view alerts' . . . which are not really relevant or necessary in the process of taking care of a patient, or on completing various paperwork electronically that, for one reason or another in the VA system it's not allowed for someone else to do that work." Additionally, facility leaders reported that new screening and prevention protocols add tasks to providers' workloads that are often performed by lower-level staff in the private sector.

> You'll have a doc that's working without an assigned nurse, with a rotating clerk who may or may not be very familiar with how to be scheduling patients in that area. And it may be a different person the next week. There's clinics where the docs have to be the ones to go out to the waiting room to find the patients to bring them back to check their vital signs, et cetera. . . . That's not an efficient way to be able to utilize very expensive staff, and it keeps them from being able to see the volume of patients that they could see.

Physician assistants and nurse practitioners could perform some of the care coordination and other duties, but VA policy limits the privileges of advanced practice providers, with nurse practitioners experiencing greater limitations to their prescribing authority: "Nurse practitioners who are licensed independent practitioners, however, cannot prescribe typically to the extent of their license. Or nurses who can't do certain protocols because we implement procedures that will not allow them to do that."

All respondents indicated that their facilities have implemented the Patient Aligned Care Teams model to deliver primary care at their facility. Some respondents discussed Patient Aligned Care

Team requirements as a barrier to both taking on new primary care physicians and increasing productivity among existing ones. Patient Aligned Care Teams "teamlet" requirements necessitate that each new primary care provider be matched with a registered nurse, an administrative clerk, and a nurse case manager, tripling the number of staff that facilities must take on for each new primary care provider position: "Our administrative staff is just decimated. . . . We have four P[atient] A[ligned] C[are] Teams, so those teams should be a provider, a [registered nurse], a [licensed vocational nurse], and an administrative person. So right now, we have one out of the four here of the administrative people." Moreover, while teamlets are intended to include staff to shift many administrative and clinical tasks away from providers, in practice many providers are still doing below-license work: "In primary care . . . if you don't have your nurse there to do these CPRS alerts, you're doing them and you'll just get buried in a lot of administrative, and even the nurse shouldn't even be doing most of it, but it's the way our system is. . . . It just makes you a lot less productive." The challenges and clerical demands associated with new initiatives, such as PACT and health information technology, are likely key drivers of capacity constraints in VA primary care.

Survey data confirm the interview findings. Across both the Chief of Staff and the condition-specific modules, respondents report that the most significant barriers to productivity are related to administrative requirements. For example, 60 percent of chiefs of staff said that administrative requirements were a major impediment to productivity. Respondents across both the Chief of Staff and disease-specific modules also reported productivity was limited because many providers perform administrative activities that others could perform and because there are not enough support staff. Particular to some of the individual conditions, 42 percent of respondents for TBI reported that no-show rates for visits negatively impacted productivity "a lot." Fifty percent of respondents for the PTSD module said that the scheduling system was inadequate, significantly impacting productivity, a concern that was also reflected in qualitative interviews.

Beyond logistical barriers to delivering care, a few respondents mentioned that the culture of VA may inhibit efficient delivery of patient care. On the provider side, one respondent described the tendency of providers to want control over their own schedules and patient load, which increases the administrative time they report. Clinical time may also be impacted by provider work preferences: "We have some providers that have been here for a long time. They've seen a set number of patients or had a way of working that was very flexible… so there's kind of a cultural shift that has to take place in order to get everyone to try to get the same level of productivity from each, struggling with some providers who want 45 minutes for their patient per appointment." On the support staff side, another respondent perceived the environment at VA as an impediment to a team-based environment, which in turn, impacts efficiency: "Often in the VA with a unionized workforce, with very specific prescribed job duties and position descriptions, it's much more of a 'no, that's not my job' or 'no, you're not my boss' whether it's said overtly or not."

3.2.4.4   Subsection Summary

In sum, we heard in the interviews that recruitment, retention, and productivity at VA facilities all contribute to capacity constraints in various ways. Representatives from all facilities we

spoke to described challenges with workforce capacity to keep up with growing patient demand for VA services. Physician shortages may be due to national or local supply of physicians, desirability of the geographic area, or space constraints in facilities, among other factors. In addition, the shortage within VA is likely influenced by retention and recruitment factors including funding for providers, salary, and human resources processes. Productivity constraints stem from challenges with recruiting and effectively utilizing support staff, infrastructure issues, technological challenges, and cultural issues that may be endemic to VA.

3.2.5 Subsection Summary

As one of the largest providers of health services in the world, VA had nearly 300,000 employees in 2014. While VA's workforce grew 15.8 percent from 2008 to 2012, the growth rate slowed over that period. Overall, contract providers account for about 3.5 percent of total workforce.

In this subsection, we described current numbers (as of FY 2014) of key provider types currently working in the VA system by total numbers of provider clinical FTEs as well as the number of clinical FTEs per 1,000 patients at a facility. We also described the relative productivity of various provider types. For physicians and associate providers, we used work RVUs per clinical FTE as measures of productivity, whereas for primary care physicians we used panel sizes and for therapist we used encounters. We identified several key challenges associated with the VA staff planning and assessment processes. These include a lack of guidance about what methods should be used, a lack of external productivity benchmarks, inaccurate or incomplete data inputs, and the inability of the data system to adequately account for certain types of providers and patient visits.

We found significant variation across facilities and VISNs in terms of productivity. Likewise, we also found variation in wait times across facilities and specialties. The greatest variations in physician productivity were in neurosurgery and thoracic surgery, while the smallest variations were in internal medicine, neurology, mental health, and surgery. In general, we found less variation in physician specialist productivity by VISN than by facility. These estimates must be considered, however, in light of concerns about coding and data quality discussed throughout this subsection.

Analysis of VA data, literature reviews, and interviews suggests that VA workforce capabilities may not be sufficient to provide timely care to Veterans across a number of key specialties as well as primary care. These constraints are influenced by a number of key factors affecting the size and productivity of the VA workforce. Particularly, interviewees reported that relatively low salaries, a slow credentialing process, and infrastructure constraints likely lead to challenges with hiring and retaining providers. Survey respondents reported that the most significant barriers to productivity are related to administrative requirements. We also found that infrastructure issues, challenges with appointment scheduling, increased clerical tasks from new initiatives, a lack of support and clerical personnel, and cultural issues likely inhibit provider productivity at VA.

3.3 Physical Infrastructure

The VA workforce is supported by a vast physical infrastructure. VA owns and leases equipment and health care sites of varying types and capabilities. In addition, VA operates housing, transportation, and other support services that assist Veterans and connect them with health care sites. VA encompasses one of the most extensive systems of health care physical infrastructure in the country. Its facilities serve approximately 9 million enrollees living in every region, from the most urban to the most rural locations. With the exception of the Military Health System, no other integrated medical system seeks to deliver every type of medical care in every region of the country. In the private sector, Kaiser Permanente may come closest, with 9.6 million members, 38 hospitals, and 618 medical offices, but Kaiser has a relatively small geographic footprint compared with VA.

VA engages in extensive efforts to plan for the delivery of health care without overinvesting in medical technologies and other costly infrastructure (Phibbs, Cowgill, & Fan, 2013). Assessment K describes capital management, construction, leasing, maintenance, and other planning processes in greater detail. In this subsection, we provide a focused inventory of the physical infrastructure and resources available in VA-owned and VA-contracted facilities. We describe, in turn, the number, types, complexity, size, and medical service capabilities of VA medical facilities, and offer an inventory of support services that help connect Veterans with care. We also discuss the role of VA's physical infrastructure in ensuring that Veterans have access to care and identify barriers or challenges faced by VA in relation to its physical infrastructure.

A summary of the methods used in these analyses is shown in the box.

Overview of Methods and Data for Assessment of Physical Infrastructure

- To assess VA's physical infrastructure, we identified and geocoded the locations of all VA health care sites, Transportation Services, and Veteran Housing Services. We also examined the number and distribution of sites by their complexity level. We identified and defined clinical care services that are definitive for one or more of the seven illustrative clinical populations.

- To examine how VA facility locations, size, complexity, and service offerings may be related to delays in care, we interviewed 29 medical facility staff and Veteran advocates about their experiences in the system.

- These analyses were supplemented by a literature review to understand the proportion of Veterans within a certain distance or travel time from a facilities or care, and to identify barriers and facilitators to geographic access.

- Data sources used in these analyses included the Veterans Affairs Site Tracking System, American Community Survey, American Hospital Association 2014 Annual Survey of Hospitals, VA Planning Systems Support Group Enrollee file, VHA Daily Bed Report, FY 2015, VA Veterans Transportation Program, 2015, HUD VASH Utilization Report, HUD 2014 Raw Housing Inventory Count, VA Surveys (Complementary and Alternative Medicine, Cardiovascular Specialty Care Services, Emergency Departments, Pain Management, Physical Therapy, Prosthetics and Sensory Aids Service, Recovery Oriented Mental Health Care,

---

> Surgical Services), VA Clinical Inventory Facility Profile Report, and VA Clinical Inventory Facility Services Report.
>
> - For complete details of the methods used to assess physical infrastructure, please refer to Section 2 of this report and Appendix A-3.

3.3.1 VA Health Care Sites

VA organizes its health care sites in a kind of nested structure. At the highest level, all sites are associated with one of 21 VISNs, which manage all resources within their service areas.[21] At the next level, every health care site falls under an "administrative parent"—a single leadership group that oversees a collection of health care sites (VA, 2013f) and is headed by a director. VAMCs can provide both inpatient and outpatient services. There are also free-standing health care sites (meaning they are not co-located with a VAMC), as described in Table 3.3-1.

Table 3.3-1. Types and Numbers of VA Health Care Sites

Site Type	Definition	Total	Medical Facility Total
Hospital	Any VA-owned, -staffed, and -operated facility providing acute inpatient and/or rehabilitation services	144*	144*
VAMC	A VA point of service that provides at least two categories of care (inpatient, outpatient, residential, or institutional extended care)	166	163
Health care centers	A VA-owned, VA-leased, contract, or shared clinic operated at least five days per week that provides primary care, mental health care, and on-site specialty services, and performs ambulatory surgery and/or invasive procedures that may require moderate sedation or general anesthesia	14	14
Multi-specialty CBOC	A VA-owned, VA-leased, mobile, contract, or shared clinic that offers both primary and mental health care as well as two or more specialty services on-site	185	185
Primary care CBOC	A VA-owned, VA-leased, mobile, contract, or shared clinic that offers both medical (on-site) and mental	509	509

---

[21] The VISNs are numbered through 23, but several were merged, so there are no VISNs 13 and 14.

Site Type	Definition	Total	Medical Facility Total
	health care (either on-site or by telehealth), and may offer support services such as pharmacy, laboratory, and X-ray		
Other outpatient services site	Sites that do not meet the criteria to be classified as a CBOC or health care center	74	0
Extended care	Encounters between Veterans and providers in either VA institutional care or VA non-institutional care	2	0
Domiciliary residential care treatment program	Encounters between Veterans and providers within the VA health care system that require an overnight stay in residential bed sections	4	0
Total		955	871

Source: Definitions, VA table comparing old to new Veterans Affairs Site Tracking System definitions. Number of facilities, Veterans Affairs Site Tracking System data, second quarter 2015.

Notes: Facility counts changed over the study period as a result of site reclassifications. The numbers in this report come from an April 2015 extract from the Veterans Affairs Site Tracking System that followed a major VHA site reclassification in March of 2015. We received the extract on April 15, 2015. Other assessments may have used Veterans Affairs Site Tracking System extracts from other dates, which were based on earlier definitions and therefore have different facility counts, or based on a proposed classification system from 2014 differing in some ways from the actual new classifications.

*All hospitals are also considered VAMCs.

A new VA site classification system was adopted in March 2015 (VA, 2013f, VHA, Office of the Assistant Deputy Under Secretary for Health for Policy and Planning, 2015).[22] Most, but not all, VA sites that offer health care services are considered "medical facilities." The Veterans Affairs Site Tracking System facility database identified 955 sites as of the second quarter of FY 2015. Of these, 871 are considered medical facilities, and 84 are nonmedical facilities. The nonmedical facilities include 74 "other outpatient services sites," which provide outpatient services but do not meet classification criteria as a CBOC or health care center; three VAMCs;[23]

---

[22] The handbook defining the new classifications was published in December 2013, but they were not formally implemented until March 2015.

[23] These three VAMCs offer at least two categories of care, but not inpatient care, and do not meet VA criteria as outpatient medical facilities. According to information provided by VA's Planning System Support Group, only VAMCs that have an outpatient classification of health care center, multispecialty CBOC, or primary care CBOC

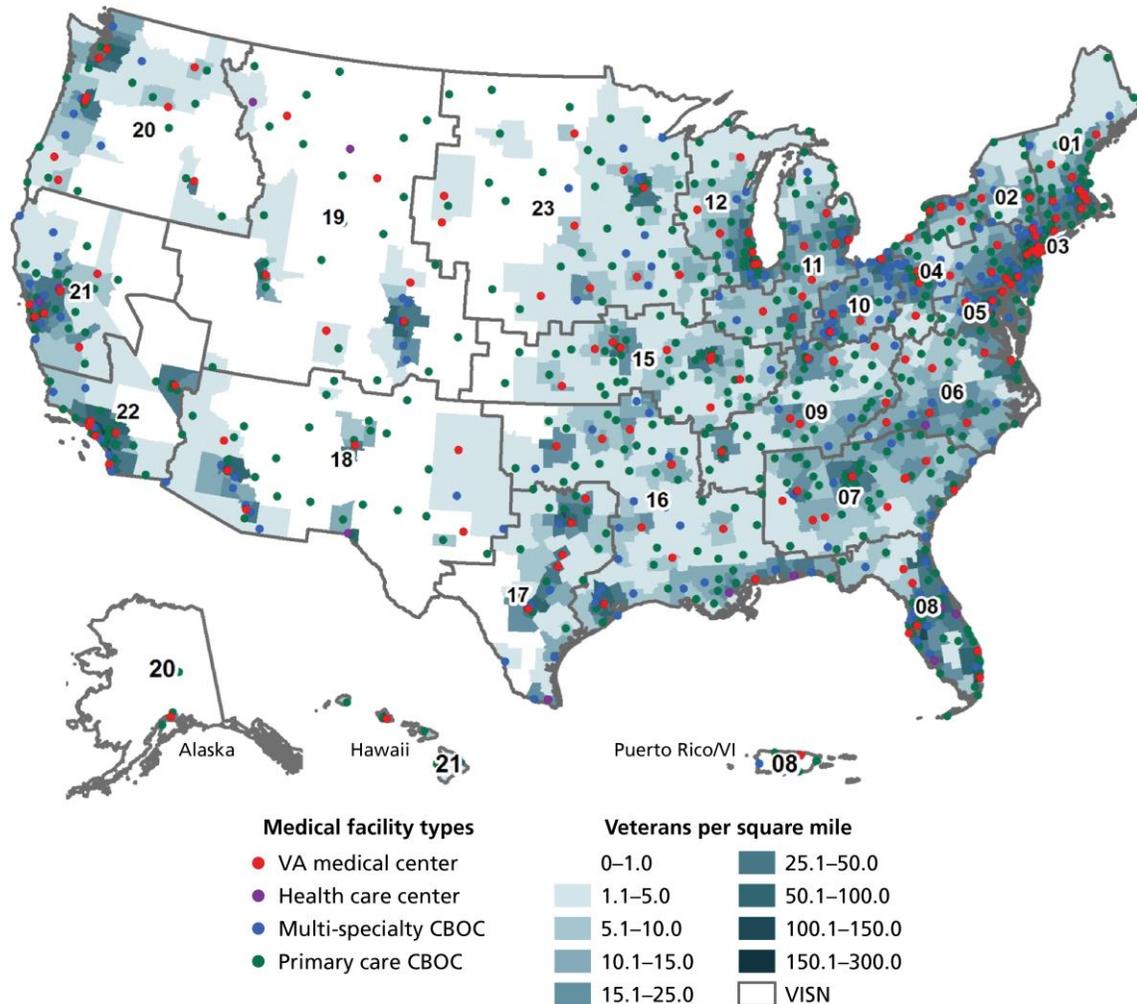
two extended care sites; and four domiciliary residential care treatment program sites. Note that every hospital is also part of a VAMC; there are no "free-standing" hospitals.

Figure 3.3-1 shows the locations of the four medical facility types, Veteran population[24] densities, and boundaries of the 21 VISNs. VA medical facilities are concentrated in the Northeast, Mid-Atlantic, and West Coast regions, where large numbers of Veterans live. VA medical facilities are less concentrated in the Southwest, plains states, mountain states, and Northwest, where fewer Veterans live. Section 4 discusses geographic access to VA care in more detail.

---

are considered medical facilities. This applies to four VAMCs; however, one of these also contains a hospital, so it retains its designation as a medical facility.

[24] This refers to the entire Veteran population, not just enrollees. Although non-enrollees cannot use VA medical facilities, they could potentially enroll in the future.

Figure 3.3-1. Locations of VA Medical Facilities and the Veteran Population Density


Sources: Authors' analysis of facility and location information from Veterans Affairs Site Tracking System data, second quarter 2015. Veteran population density expressed as number of Veterans per square mile based on Assessment A projections, which utilize American Community Survey data.

3.3.2 Facility Size and Usage

VA facilities vary widely in size and usage, much like those in the private sector. Tables 3.3-2a and 3.3-2b presents two measures of facility size, expressed as rates per 10,000 enrollees by VISN. The first measure is the number of operating hospital beds for the time period selected; the count excludes beds that are temporarily closed for any reason. The second measure, average daily census, is the average number of inpatients per day of service.[25] This is calculated

---

[25] VA does not report outpatient daily census.

by dividing cumulative bed days of care for the fiscal year to date by the number of calendar days in service (VSSC, 2011). The third measure, bed occupancy, is the average inpatient daily census divided by the total number of hospital beds.

Table 3.3-2a. VA Operating Beds per 10,000 Enrollees, by Bed Type

	Hospital	Nursing Home	Domiciliary	CWT/ TR
National average	18.3	14.9	8.5	0.7
VISN Min, max	11.5, 43.4	7.0, 33.7	4.1, 17.6	0.0, 2.7
VISN interquartile range	14.8, 20.2	11.4, 19.8	5.9, 13.4	0.4, 0.9

Table 3.3-2b. VA Average Daily Census per 10,000 Enrollees, by Bed Type, and Hospital Bed Occupancy

	Hospital	Nursing Home	Domiciliary	CWT/ TR	Bed Occupancy
National average	11.0	10.2	6.2	0.5	60%
VISN Min, max	7.3, 15.8	5.4, 20.1	2.9, 14.6	0.0, 1.9	36%, 70%
VISN interquartile range	9.0, 12.8	6.6, 14.8	4.1, 10.3	0.2, 0.6	59%, 64%

Sources: Operating Beds and Average Daily Census from VHA Daily Bed Report, FY 2015. Enrollee population from VA Planning Systems Support Group Enrollee file (Phibbs, Cowgill, & Fan, 2013).
Notes: CWT/TR is Compensated Work Therapy Transitional Residential. The interquartile range is estimated by ranking VISN-level estimates from lowest to highest and reporting estimates at the 25th and 75th percentiles.

There are various types of hospital beds within VAMCs (Tables 3.3-2a and 3.3-2b). Hospital beds may be designated for specific uses: blind rehabilitation, internal medicine, neurology, psychiatry, rehabilitation medicine, spinal cord, and surgery. Nursing home beds are for patients requiring long-term care. Domiciliary beds are for Veterans in various residential care programs (see VA, 2010).[26] CWT/TR beds are for Veterans in that rehabilitation program.

On average, the VA system has 18.3 hospital beds per 10,000 enrollees and an inpatient daily census of 11 patients per 10,000 enrollees. This works out to 60-percent average occupancy across VA facilities. Among the 21 VISNs, occupancy ranges from a high of 70 percent to a low of 36 percent. VISNs cluster tightly in the middle 50 percent of the distribution; there are long

---

[26] This includes the Domiciliary Care for Homeless Veterans program, which is also discussed in Section 3.3.1.4, Support Services.

"tails" below the 25th and above the 75th percentiles. This suggests that efforts to reduce variation in occupancy could be focused on outliers.

Hospital bed supply varies widely across VISNs, with a maximum 43.4 hospital beds per 10,000 enrollees (the VISN with the highest bed supply also has the lowest occupancy rate). The other bed types have higher usage (data not shown) than hospital beds: Nursing home beds are, on average, 69 percent occupied, domiciliary beds are 73 percent occupied, and CWT/TR program beds are 70 percent occupied.

VA also operates a number of mobile medical units, which are vans or other large vehicles equipped to deliver certain types of care in rural areas or to be deployed in case of large-scale emergencies. According to a 2014 audit, VA operated at least 47 mobile medical units, but the audit lacked the exact number and the amount of patient use (VA, Office of Inspector General, 2014c).

3.3.3 Facility Complexity

A large share of VA medical facilities is classified as "high complexity" (Table 3.3-3). The complexity level is based on the patient populations, clinical services, educational and research missions, and administrative structure of the administrative parent and its satellite facilities (VHA Office of Productivity, Efficiency, and Staffing, 2015).[27] Medical facilities are classified in three levels, with Levels 1a–1c representing the most complex facilities; Level 2, moderately complex facilities; and Level 3, the least complex facilities. Table 3.3-3 shows the complexity level of the administrative parents; all medical facilities are assigned the same complexity level as the parent.

Table 3.3-3. Count of VA Administrative Parents by Level of Complexity

Complexity	Administrative Parents— Number	Administrative Parents—%
1a - High	32	23
1b - High	15	11
1c - High	27	19
2 - Medium	32	23
3 - Low	31	22
Excluded	3	2
Total	**140**	**100**

---

[27] Seven variables are considered in estimating facility complexity: volume and patient case mix, clinical services provided, patient risk calculated from VA patient diagnosis, total resident slots, an index of multiple residency programs at a single facility, total amount of research dollars, and the number of specialized clinical services.

Source: Veterans Affairs Site Tracking System data, second quarter 2015.

Notes: The numbers in this report come from an April 2015 extract from Veterans Affairs Site Tracking System that followed a major VA site reclassification in March of 2015. One administrative parent, in the Philippines, is not included in the table because its complexity level was not available.

3.3.4 Service Provision

In addition to sites where health care is delivered, VA's physical infrastructure includes the medical technology[28] used at VA facilities for specific health services. Examples include imaging equipment, specialized surgical suites, emergency departments, consultation rooms for outpatient services, and beds for inpatient services. For this report, we focus on 27 services used in the care of seven illustrative clinical populations at VA and non-VA medical facilities. In Table 3.3-4 we present the seven populations, the 27 services, and the number of VA medical facilities that provide the services.

Table 3.3-4. Number of VA Sites with Selected Clinical Population-Specific Services

Services (by Clinical Population)	Number of Facilities (% of 933* Total Health Care Sites)
Acute Coronary Syndromes	
Non-invasive cardiology services	170 (18)
Emergency department	114 (12)
Coronary care unit	112 (12)
Interventional cardiology	79 (8)
Telemetry (if Critical Care Unit [CCU]/Intensive Care Unit [ICU] is not available)	77 (8)
Diagnostic cardiac catheterization	76 (8)
Cardiac surgery	75 (8)
Colon Cancer	
Primary care clinic	895 (96)
Computerized tomography scan	175 (19)
Oncology services	168 (18)
Colonoscopy	167 (18)

---

[28] Medical technology can be considered distinct from medical IT, an important capital resource that is described in Subsection 3.5 of this report.

Services (by Clinical Population)	Number of Facilities (% of 933* Total Health Care Sites)
Surgical services	130 (14)
TBI	
Specialty care	207 (22)
Polytrauma support clinic team	88 (9)
Polytrauma network site	23 (2)
Polytrauma Rehabilitation Center (Program)	5 (1)
Type II Diabetes Mellitus	
Primary care clinic	895 (96)
Diabetes specialty or endocrinology clinic	379 (41)
Podiatry clinic	323 (35)
Ophthalmology clinic	169 (18)
PTSD	
Mental health services	848 (91)
Psychotherapy	672 (72)

SUD	
Mental health services	848 (91)
Outpatient specialty care	549 (59)
Methadone	347 (37)
Inpatient detoxification	146 (16)
Residential treatment	64 (7)
Conditions Requiring Gynecological Surgery	
Gynecological surgery services	98 (11)

Source: RAND estimates derived from the VA Planning Systems Support Group (PSSG) Enrollee file, the VA Clinical Inventory Facility Profile Report, and the VA Clinical Inventory Facility Services Report datasets extracted on February 4, 2015. Discrepancies between our counts for individual services and those from other data extracts have two sources: a) there are minor changes over time in reported inventory counts b) our counts of some services represent combinations of variables from our sources. Appendix table F-10 documents the specific

variables we used to construct our counts for each service.

Notes: *The total number of VA facilities that could potentially deliver health care services is 955. However, inventories of condition-specific services were missing for 22 facilities.

3.3.5 Support Services

Other VA resources and capabilities help to connect a Veteran to medical care. These include Veterans Centers, transportation services, and housing services.

Veterans Centers. Veterans Centers provide counseling, outreach, and referral services to Veterans and their family members. The 300 centers in 2010 served 191,000 people (VHA, 2015).

Transportation Services. Transportation Services support Veterans who are unable to drive to medical facilities. VA runs some programs directly, while independent organizations run others. VA had approximately 80 transportation programs that it managed or purchased nationwide as of April 2015, and we obtained data for 75 of them from transportation services managers. The 75 programs collectively serve 310 CBOCs and 154 other locations with 834 vehicles. Data on the number of Veterans served and the number of rides provided was not available. While a number of states, counties, VSOs, and possibly other organizations also provide transportation services to Veterans, we were unable to identify comparable data on their services. All VISNs except VISN 4 have some type of transportation available, but some serve more locations than others (Table 3.3-5).

Table 3.3-5. VA Transportation Services by VISN

VISN	Number of Vehicles	Number of CBOCs Served	Number of Native American Reservations Served	Number of Vet Centers Served	Number of State Veteran Homes* Served

Source: VA Veterans Transportation Program, 2015.
Notes: *State Veteran Homes provide nursing home or adult day care services to Veterans. They are formally recognized and surveyed by VA but they are operated by individual states.
**Data for VISN 4 were not reported (NR).

Housing Programs. Housing programs serve Veterans who might otherwise be homeless. A January 2014 estimate put the number of homeless Veterans at approximately 50,000, down from 150,000 five years earlier (National Alliance to End Homelessness, 2015). Programs include direct VA housing programs, vouchers for community programs, and services that assist homeless Veterans but do not provide beds. In FY 2014, VA provided specialized homeless services to almost 265,000 Veterans and made available approximately 80,000 beds, both directly and through community partners. These beds were provided through four programs (VA, 2014i):

- The Housing and Urban Development–Veterans Affairs Supportive Housing (HUD-VASH) Program has provided more than 58,000 rental vouchers to Veterans.
- The Homeless Providers Grant and Per Diem Program, which makes grants to community-based agencies to programs transitional housing, provides about 15,000 beds.
- The Domiciliary Care for Homeless Veterans program provides time-limited residential treatment to homeless Veterans with mental health and substance use disorders. Approximately 2,500 beds were available at 48 sites.
- Health Care for Homeless Veterans provides outreach and case management to homeless Veterans, and operates approximately 4,000 beds.

VA directly provides services under the latter two programs. While the areas served by most VAMCs have some housing services available, Table 3.3-6 shows a high ratio of vouchers and Homeless Providers Grant and Per Diem Program beds to the enrollee population in VISN 22. VISN 21 provides a high number of Health Care for Homeless Veterans beds.

Table 3.3-6. Housing Services per 10,000 Enrollees, by VISN, 2015

Sources: HUD-VASH Vouchers, HUD-VASH Utilization Report, December 2014; these figures reflect vouchers available as of December 2014, rather than the number used in 2014. Bed counts, FY 2015 Bed Report. Supportive Services for Veteran Families and Permanent Supportive housing projections developed by the VA Center for Applied Systems Engineering, based on HUD's 2014 Raw Housing Inventory Count.

Notes: HUD-VASH Vouchers: Housing and Urban Development–Veterans Affairs Supportive Housing Program vouchers for rental assistance. SSVF: Supportive Services for Veteran Families. Domiciliary Care for Homeless Veterans is a subset of the broader domiciliary programs described in Subsection 3.3.2, so these numbers represent a portion of the numbers in Table 3.3-2.

VA's Supportive Services for Veteran Families program funds non-VA organizations to provide services that promote housing stability among low-income Veteran families. In FY 2014, the program served almost 124,000 individuals—about 77,000 of them Veterans.

Finally, some Veterans find permanent supportive housing (in facilities that provide case management to persons with disabilities or other conditions that make it difficult to live independently) with non-VA organizations, some of which reserve beds for Veterans. VA estimates the number of beds reserved for Veterans at 6,400 (VA Center for Applied Systems Engineering based on HUD's Raw Housing Inventory Count). However, VA does not directly fund these services.

3.3.6 VA Physical Infrastructure and Access to Care

We interviewed 29 individuals in leadership or clinical care positions at VISNs, VAMCs, or CBOCs about their experiences with VA physical infrastructure. When other respondents, including Veteran advocates, spontaneously commented on infrastructure, we also included their comments. Respondents were generally satisfied with the availability and quality of VA medical equipment and supplies, though this varied across facilities and types of equipment. Few interviewees raised concerns about oversupply of infrastructure, but evidence suggests that decommissioned facilities are only slowly repurposed, and facility and Central Office leaders pointed out that maintenance of these facilities is costly.

Physical space was most commonly cited as being in short supply, and many interviewees said that this perceived shortage limits provider productivity and increases the need for non-VA

inpatient care, in particular. VAMC leadership and clinical staff discussed the need to continually update physical space to keep pace with the evolving needs of medical equipment (for example, physical space, network connectivity) and changing standards for best practices in patient care (for example, single-occupancy rooms to improve patient experience and infection control). This was especially true for respondents working in older facilities. Some described how, over time, incremental expansions and renovations have resulted in work environments that negatively affect productivity and/or patient experience because the resulting facilities feel disconnected, "cobbled together," or overcrowded.

Interviewees identified several barriers to increasing construction, leasing space from non-VA facilities, or reconfiguring or repurposing existing space. For example, the approval process for new construction can be lengthy and challenging (Assessment K describes these challenges in detail). Some respondents indicated that, when new construction is completed, the facility may no longer meet existing needs; however, construction was generally seen as positively contributing to patient care and provider productivity. Similarly, at times leasing new space was also described as such a time-consuming process that even "emergency leases" are not obtained quickly enough to respond to ever-changing needs.

3.3.7 Subsection Summary

VA operates one of the most extensive systems of health care infrastructure in the country. Of 955 sites, 871 are medical facilities; the remaining sites, considered nonmedical facilities, generally provide outpatient services or residential treatment. VA medical facilities are concentrated in regions with the most Veterans: the Northeast, Mid-Atlantic, and West Coast. A large share of VA medical facilities are classified as "high complexity," which is based on the patient populations, clinical services, educational and research missions, and administrative structure of the administrative parent and its satellite facilities.

On average, the VA system has 18.3 hospital beds per 10,000 enrollees and an inpatient daily census of 11 patients per 10,000 enrollees, for an occupancy rate of 60 percent. Hospital bed supply varies widely across VISNs, with a maximum 43.4 hospital beds per 10,000 enrollees (the VISN with the highest bed supply also has the lowest occupancy rate).

VA's physical infrastructure also includes medical technology such as imaging equipment, specialized surgical suites, and emergency departments, as well as resources including Veterans Centers, housing programs, and transportation services. Interviewees in leadership or clinical care positions are generally satisfied with VA medical equipment and supplies, but they note that physical space is in short supply and even new facilities can quickly grow out of date. Interviewees identified several barriers to increasing construction, leasing space from non-VA facilities, or reconfiguring or repurposing existing space, including a lengthy approval process and changing needs.

In the next subsection, we consider additional resources and capabilities available to VA through relationships with non-VA partners.

3.4   Interorganizational Relationships

Relationships with non-VA partners represent additional resources and capabilities that VA can utilize to provide timely and accessible care to Veterans. Veterans may use purchased care when VA cannot provide the care, VA care is not geographically accessible, VA cannot provide the care in a timely manner, or when care can be provided more cost-effectively by a partner. Care is provided to VA enrollees by non-VA entities through several programs and various types of payment or contractual arrangements that VA has negotiated with its partners.

In this subsection, we describe the complex web of arrangements that VA has in place to provide care to Veterans, including the different types of arrangements for care provision, the volume of patients seen under these arrangements, and expenditures. We begin with an overall summary of the purchased care program (Subsection 3.4.1) and then discuss two main components of purchased care: VA programs for community care (Subsection 3.4.2) and VA partnerships to deliver care (Subsection 3.4.3). In Subsection 3.4.4, we briefly describe the process of selecting a purchased care program, a topic discussed in detail in Assessment C. We also describe challenges in utilizing care delivered by non-VA entities (Subsection 3.4.5) and provide a summary (Subsection 3.4.6).

A summary of the methods used in these analyses is shown in the box.

Overview of Methods and Data for Assessment of Interorganizational Relationships

- We used several measures to describe the extent of care provided through relations with non-VA entities. Measures of utilization included purchased care outpatient visits, mental health outpatient visits, and patients treated in non-VA inpatient settings compared with VA facility utilization. We also measured total VA spending on various categories of purchased care as well as care purchased from VA partners such as DoD and the Indian Health Service.

- We performed a targeted literature search to obtain information on VA purchased care. To obtain additional context and detail regarding the various types of VA purchased care and the challenges associated with accessing, utilizing, coordinating, and reimbursing care, the team reviewed qualitative information gathered from interviews conducted by Assessments B, C, and I, and responses to questions contained in the 2015 Survey of VA Resources and Capabilities regarding the use of non-VA medical care.

- Data sources used in these analyses included the VA/DoD Medical Sharing Office VA Fee Basis Claims System data extract from Assessment I, VA Central Fee data extract from Assessment C, and VA Budget Requests 2012-2015.

- For complete details of the methods used to assess interorganizational relationships, please refer to Section 2 of this report.

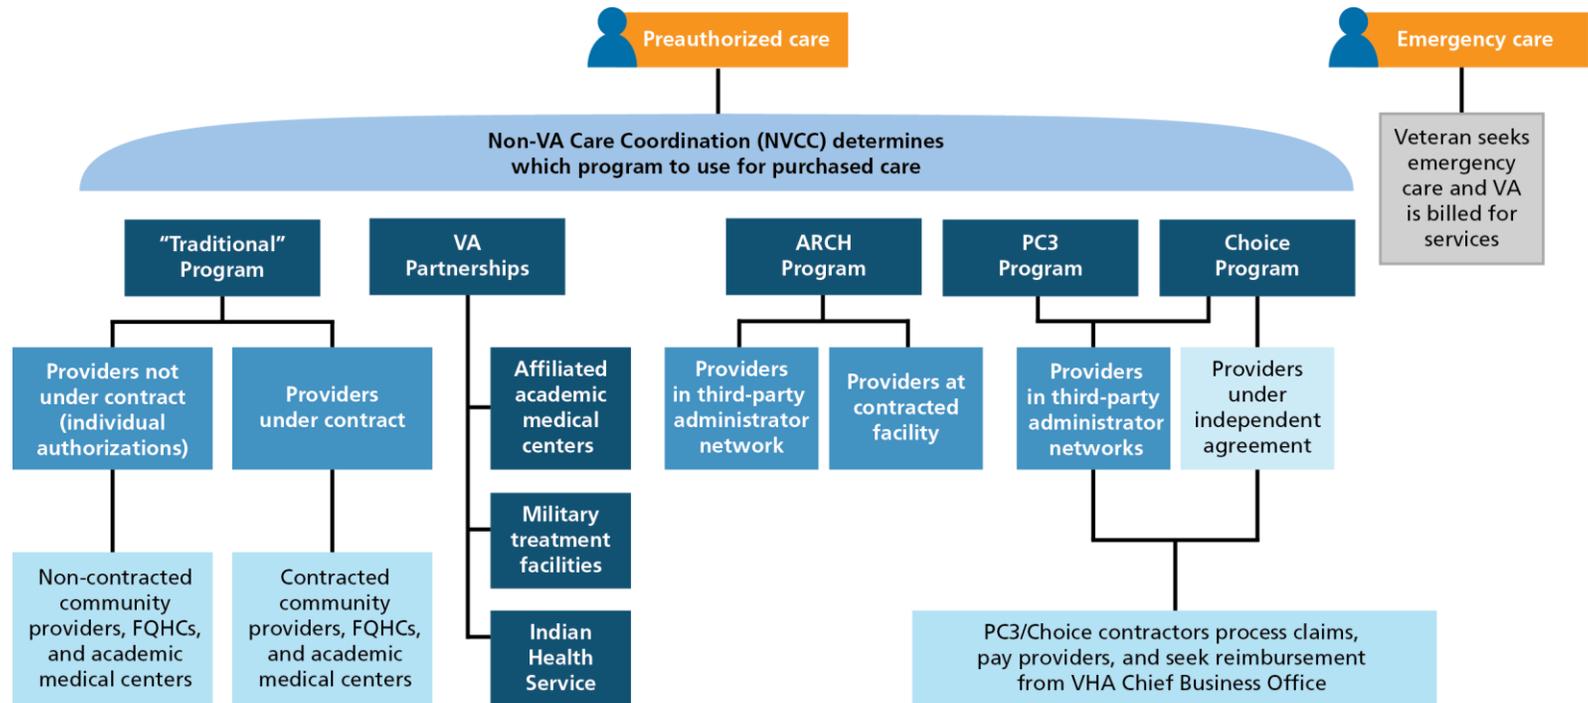
3.4.1   Overview of VA Purchased Care

VA has multiple channels through which it purchases care for enrolled Veterans from non-VA providers. Purchased care may be either *emergency* or *preauthorized*; an authorization for

treatment in the community is required for any purchased care other than an emergency. VA reimburses the costs of emergency transportation and medical care at non-VA facilities for service-connected medical conditions and for Veterans who have no other source of payment for the care.[29] Before the passage of the Veterans Choice Act, VA *had the option* to offer care in the community if VA services were geographically inaccessible or if VA facilities were not available to meet a Veteran's needs. Preauthorized programs include the "traditional" program, care obtained through partnership agreements, the ARCH pilot, the PC3 program, and the Veterans Choice Program (Figure 3.4-1). Assessment C examines these mechanisms in detail along with the underlying authorities through which VA purchases care. In this subsection, we quantify, to the extent possible, the contribution of these programs and partnerships to VA's resources and capabilities. We briefly discuss each program in Subsection 3.4.2.

---

[29] The Veterans Millennium Health Care and Benefits Act allows for payment of emergency care not related to service-connected conditions under certain circumstances.

Figure 3.4-1. VA Purchased Care Programs and Partnerships


Source: Authors' analysis of VA documents.

The Non-VA Medical Care program,[30] formerly known as "fee care" or "fee-basis care," refers to all care for enrolled Veterans provided in non-VA facilities and paid for by VA (we refer to this as "purchased care"). It has evolved from a very small program initiated in 1945[31] into a substantial source of care for enrolled Veterans. Spending for purchased care captured by the Fee Basis Claims System increased from $3 billion in FY 2008 to $5.5 billion in FY 2014.[32] Additional spending not captured by the Fee Basis Claims System, such as payments to state nursing homes and lump sum payments under some contracts, brings the total of 2014 purchased care payments to $7 billion,[33] which represents 15 percent of the VA medical services budget (Office of Management and Budget, 2015). The top categories of medical care purchased through the program are dialysis (national contract), skilled and unskilled home health services, radiation therapy, diagnostic testing, physical therapy, inpatient hospitalization, and emergency care (Office of Management and Budget, 2015). This mix could change moving forward as utilization of purchased care under the Veterans Choice Program increases.

Across all programs, outpatient medical care represents the largest share of VA purchased medical care expenditures, accounting for about 36 percent of total purchased medical care spending ($20.3 billion) for FY 2008–2012 (Table 3.4-1). From FY 2011 to FY 2014, the number of non-VA outpatient visits increased from 12.2 million to 14.2 million, though they remained at about 15 percent of total VA outpatient visits (Figure 3.4-2).

Table 3.4-1. VA Spending by VA Purchased Care Category, FY 2008–FY 2012

Type of Care	Percentage of All Purchased Medical Care Expenditures
Preauthorized outpatient—Medical	36.3
Preauthorized inpatient	22.7
Home health	13.3
Community nursing home	12.3
Emergency care for Veterans for non-service-connected conditions	8.8
Emergency care for Veterans with service-connected conditions	4.5

---

[30] This new name was established in 2013 to promote clarity since the terms "fee care" and "fee-basis care" were used inconsistently.

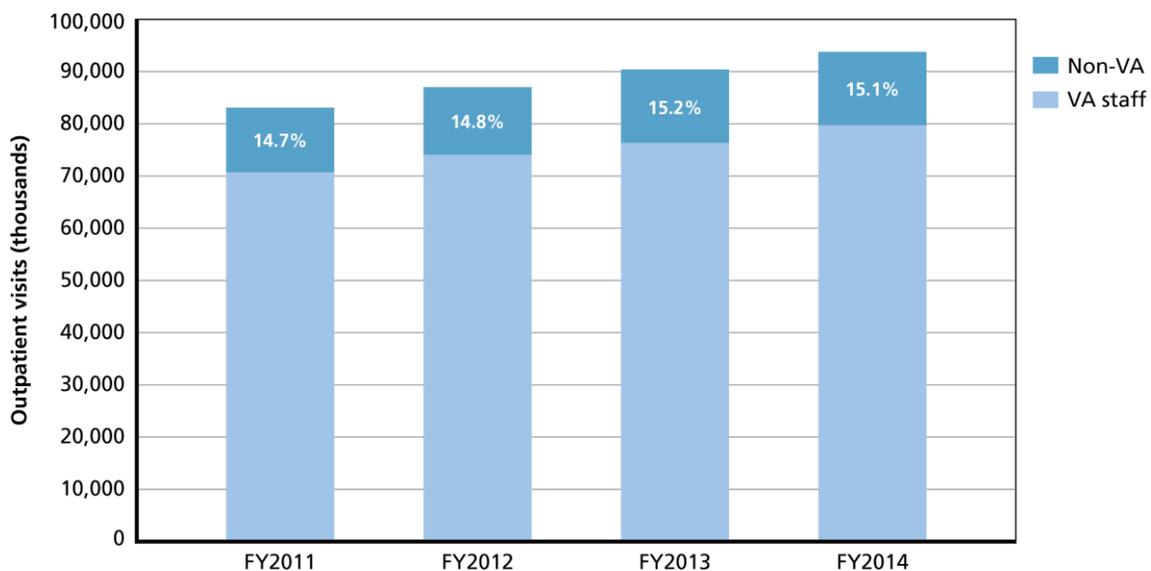
[31] The Chief Medical Officer of VA recognized that many hospital admissions of World War II Veterans could be avoided by treating them before they needed hospitalization and instituted a program for "hometown" medical and dental care at government expense for Veterans with service-connected ailments.

[32] This figure is based on a data extract provided by VA to Assessment I.

[33] We were unable to fully reconcile the difference between the $5.5 billion figure in the data extract from VA and the $7.0 billion figure included in the OMB document.

Type of Care	Percentage of All Purchased Medical Care Expenditures
Preauthorized outpatient—Dental	1.8
Compensation and pension exams	0.3
Total	100.0

Source: Adapted from Table 2 ("VA Spending and Utilization by Fee Basis Care Category, FY 2008 Through 2012") in GAO, 2013c.

Figure 3.4-2. Number of VA and Purchased Care Program Outpatient Visits, 2011–2014


Source: Authors' analysis of VA Congressional Budget Submissions 2012–2015.
Note: Includes mental health outpatient visits.

Mental health outpatient care is one of the few categories of care for which utilization data are readily available. Mental health care is provided mostly at VA facilities; in 2014, only 2.3 percent of these visits involved non-VA providers (Table 3.4-2). We were unable to identify recent data on the volume of other categories of outpatient purchased care, such as primary care. Inpatient (non-ambulatory) care accounts for the second highest level of purchased care spending, and in 2014, 22 percent of VA enrollees who received inpatient care were treated at non-VA facilities (Table 3.4-3).

Table 3.4-2. Number of VA-Provided and VA-Purchased Mental Health Outpatient Visits, FY 2014

	VA Care	Purchased Care	% Purchased Care
Mental Health Outpatient Visits	11,874,040	270,308	2.3

Source: Office of Management and Budget, 2015.

Table 3.4-3. Number of Patients Treated in VA and Non-VA Inpatient Settings, FY 2014

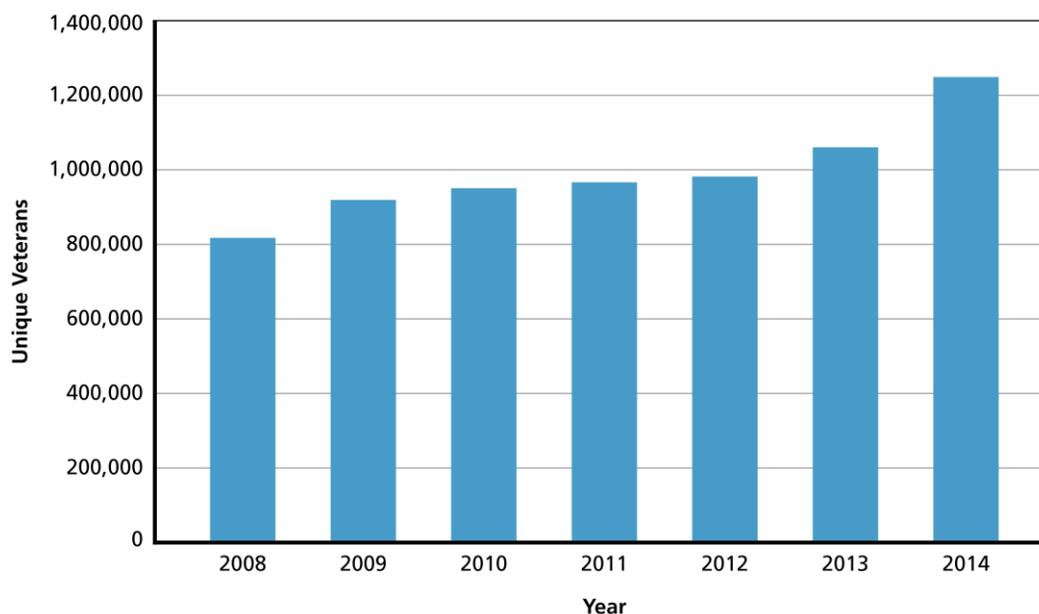
	VA Facilities	Non-VA Facilities	% Non-VA
Patients Treated in Inpatient (nonpsychiatric) Facilities	483,800	136,760	22.0

Source: Office of Management and Budget, 2015.

From 2008 to 2014, the number of unique Veterans utilizing purchased care increased by about 52 percent (Figure 3.4-3), and in 2014, 20 percent of all VA medical care users utilized some purchased care. Some demographic groups of VA enrollees rely more heavily on purchased care than others. As an example, 33 percent of women Veteran patients received at least some outpatient care through the Non-VA Medical Care Program in 2010 compared with 16 percent of men, and highly rural[34] women VA patients were more likely than highly rural men to use non-VA outpatient services (54 percent of highly rural women compared with 29 percent of highly rural men) (Frayne & Mattocks, 2012). VA facilities may lack the necessary volume of women patients to support the required care (for example, mammography) or have not historically provided particular gender-specific types of care (for example, obstetrical care) (Frayne & Mattocks, 2012).

---

[34] VHA defines "highly rural" as patients with addresses located in a county with fewer than seven residents per square mile, on average.

Figure 3.4-3. Number of Unique Veterans Who Received Purchased Care, 2008–2014


Source: Data extract from VA Central Fee Payment Files provided to Assessment C.

There is significant variation in purchased care spending across VAMCs. In 2014, the mean amount spent among VA stations that had purchased care claims was $38.4 million; the highest amount was $151 million. VISNs 8 and 20 each had multiple VAMCs within the top 10 for spending on purchased care in the period 2012–2014.[35]

3.4.2 VA Programs for Purchased Care

VA has multiple programs and partnerships through which it may arrange care for Veterans with non-VA providers. Some VA partners, such as Federally Qualified Health Centers (FQHCs) and academic medical centers, may participate in multiple programs. We briefly describe each of these options below.

3.4.2.1 Traditional Program

In its traditional program, VA provides either individual authorizations for care with a non-VA provider (or a fee card for a small group of rural Veterans) or it contracts with local providers, academic medical centers, or FQHCs for particular services as needed. Prior to 2011, VA paid providers on an internally developed fee schedule or based on Medicare rates, which resulted in variability across VAMCs and VISNs. In 2011, VA began using applicable Medicare rates consistently, which likely contributed to a slight decline in total spending for purchased care in FY 2012 (GAO, 2013c). Individual authorizations and local contracts for purchased care have

---

[35] These numbers are derived from authors' analysis of the data extract VA provided to Assessment I.

been supplemented and, in some circumstances, replaced by other vehicles as VA attempts to standardize its purchasing process, performance metrics (for example, for access and medical records sharing), and reimbursement rates. VA has determined that any future local contracts with non-VA providers must "produce benefits beyond PC3 (see Subsection 1.1.2.3) or address a need beyond PC3" (Robinson, June 11, 2014), and we learned in our interviews that this policy is updated to cover care provided through the Veterans Choice Program.

3.4.2.2 ARCH Program

The ARCH program is a small pilot, established in 2011 and initially intended to run for three years, aimed at improving access for Veterans in rural and underserved areas. The pilot was implemented at five sites (Pratt, KS; Caribou, ME; Farmville, VA.; Flagstaff, AZ; and Billings, MT), two of which chose to provide primary care, and three of which chose specialty care. Participation was limited to Veterans living in those counties who were enrolled when the pilot started and met one of three criteria: (1) lived more than 60 minutes driving time from the nearest VA health care facility providing primary care; (2) lived more than 120 minutes driving time from the nearest VA acute care facility; or (3) lived more than 240 minutes from the nearest VA tertiary care facility. Humana Veterans Health Services and Cary Medical Center (Maine only) serve as the third-party administrators. A recent evaluation of the initial three-year pilot reported that 5,945 Veterans received care through 27,705 outpatient encounters and 1,073 inpatient discharges (Altarum Institute, 2015). The pilot was extended to 2016 as part of the Veterans Choice Act legislation.

3.4.2.3 PC3 Program

The PC3 program was initiated in 2012 as a follow-on to an earlier pilot program that also used a third-party administrator in an attempt to improve the management and oversight of purchased care.[36] The PC3 program was intended to address some of the identified weaknesses in VA's traditional purchased care vehicles, such as lack of provider credentialing, mismanagement of local contracts, variability in reimbursement rates, untimely and inaccurate payment of provider claims, and inadequate sharing of medical documentation by external providers, while addressing the need to provide more timely care to Veterans.

In the fall of 2013, VA awarded two regional contracts to Health Net Federal Services and TriWest Healthcare Alliance to provide external care for Veterans when a VAMC determines that it cannot provide the needed care due to a lack of specialists, geographic inaccessibility, and other factors. The program began in April 2014 after an approximate six-month implementation period in which the administrators built their provider networks and established the necessary infrastructure. Initially, PC3 was focused on specialty care, including

---

[36] Project HERO (Healthcare Effectiveness through Resource Optimization) was a pilot program implemented in four VISNs between 2007 and 2013 that utilized third-party administrators with networks of primary and specialty care providers.

---

mental health, but in August 2014 VA expanded the scope of the program to include primary care services.

PC3 contracts with the third-party administrators contain requirements for scheduling appointments within five days of receipt of VA authorization and ensuring that a patient can be seen within 30 days, providing an appointment reminder in writing, following up to ensure the appointment occurred, and paying provider claims within 30 days. Contracted providers also agree to return medical documentation within 14 days for outpatient visits and 30 days for inpatient visits. Health Net and TriWest negotiate reimbursement rates with providers that are, on average, 94.5 to 97.5 percent of Medicare rates for medical and surgical services, lower than the Medicare rates VA pays for individual authorizations (Robinson, June 11, 2014).

A recent VA Office of Inspector General review of the PC3 program (2015) reports that utilization of the program fell short of expectations in 2014, with only 6,900 completed authorizations and spending of $3.8 million for health care services. VA spent an additional $15.1 million on implementation and administrative fees for the program in 2014. VA projected utilization rates—PC3 authorizations divided by all purchased care authorizations—of 25 to 50 percent, but only achieved a 9-percent utilization rate in 2014. The VA Office of Inspector General attributes the low utilization to a combination of inadequate provider networks and lack of a strong implementation plan to ensure that VAMCs use the PC3 program over individual authorizations. If VA implementation costs are prorated over the base year and four option years, the FY 2014 PC3 contract cost would total about $7 million. In comparison, the VA Office of Inspector General estimates that the cost of providing the care through individual authorizations would have been $4 million. This $3 million additional cost compares to a VA estimate of $13 million in savings for FY 2014 as a result of the new program. The third-party administrators continue to attempt to add providers to their networks as they receive better information from VA about demand for various types of care by location.

3.4.2.4 Veterans Choice Program

The most recent addition to the VA purchased care landscape is the Veterans Choice Program. Established by law in August 2014, this program empowers Veterans to seek care based on their distance from the closest VA medical facility and an inability to schedule an appointment at a VA facility within 30 days. Unless it is reauthorized, the temporary program will end when the allocated funds of $10 billion are used or no later than August 7, 2017. With only three months allowed for implementation, VA expanded its contracts with the PC3 third-party administrators, Health Net and TriWest, and they quickly established the infrastructure for the program. As such, all PC3 providers are automatically eligible to be Veterans Choice providers; those providers who do not wish to participate in the PC3 program but who would like to be a Veterans Choice provider must sign an agreement with one of the administrators. In order to participate, providers must be Medicare-eligible, agree to accept Medicare rates, and agree to submit Veteran care reports after providing medical services.

VA leadership highlighted the challenge in predicting Veteran uptake for the program, forecasting spending over the next three years that ranges from $3.8 billion and $12.9 billion (McDonald, Februrary 11, 2015). Early reports indicate lower than expected levels of utilization.

VA reported that, from the program's launch on November 4, 2014, to March 18, 2015, 46,429 Veterans had received authorizations for care under the Veteran's Choice Program, and non-VA providers had scheduled 44,461 appointments. As a comparison, in an average month, 6.4 million appointments are completed in VA and 1.3 million appointments are completed through purchased care programs (Gibson, 2015). Further, it was reported that VA is on track to spend only $1.1 billion on the program this year (Miller, April 30, 2015). To make the program available to more Veterans, VA announced in late March 2015 a change in the calculation used to determine the distance between a Veteran's residence and the nearest VA medical facility from a straight-line distance to driving distance.

3.4.3 VA Partnerships to Deliver Care

VA extends its capacity through partnerships with DoD, the Indian Health Service, academic medical centers, FQHCs, and community mental health and substance use providers.

3.4.3.1 DoD

VA and DoD collaborate to deliver benefits and services to Veterans, service members, military retirees, and beneficiaries. This partnership was established as a result of legislation that directed the organizations to look for opportunities to share medical resources,[37] and activities are overseen by the DoD–VA Joint Executive Committee. There are three vehicles for collaboration—sharing agreements,[38] joint ventures, and Joint Incentive Fund projects. Sharing agreements, which may cover a single service or multiple services, are typically negotiated by the heads of individual VA and DoD medical facilities, with review at the VISN and VA/DoD Sharing office at VA and the DoD/VA Program Coordination Office on the DoD side. Reimbursement rates for medical services are typically based on the Tricare Civilian Health and Medical Program of the Uniformed Services rate discounted by 10 percent (VA/DoD Health Executive Council, 2003), representing a savings relative to Medicare rates. Sharing agreements also allow for the exchange of services.

As of March 2015, there were 144 active VA/DoD sharing agreements nationwide between 48 VAMCs and 74 military treatment facilities for services, which include direct patient medical care; shared space; and administrative, dental, mental health, laundry, and ancillary services (VA/DoD Medical Sharing Office, March 11, 2015). Of the 74 military treatment facilities involved in sharing agreements, 38 provide direct medical care to Veterans. In 2014, VA reimbursed DoD $119.1 million for services rendered, about equivalent to the amount spent in 2013 (VA/DoD Medical Sharing Office, March 11, 2015).

VA and DoD have several joint ventures, which involve a higher level of collaboration than sharing agreements and require commitments of at least five years. Joint ventures may involve multiple health care services, joint capital planning, and shared risk. Like sharing agreements,

---

[37] Public Law 97-174, VA/DoD Health Resources Sharing and Emergency Operations Act of 1982.

[38] Sharing agreements are written contracts that allow VA to buy, sell, or exchange health care resources and services with non-VA facilities.

the local partners determine whether they wish to work together, and approval must be obtained from department-level staff at both organizations. There are 10 joint venture locations (Petzel, 2013), including the North Chicago clinic, the only integrated VA/DoD federal health care center. These locations are listed in Table 3.4-4.

Table 3.4-4. VA and DoD Joint Venture Locations

DoD Facility	VA Facility	Location
Naval Health Clinic/ Joint Base Charleston/Naval Hospital and Beaufort	Charleston VAMC	Charleston, SC
Naval Health Clinic Jacksonville	Miami VAHCS CBOC	Key West, FL
Keesler Air Force Base	VA Gulf Coast HCS	Gulf Coast FL
Wm Beaumont Army Medical Center	El Paso VAHCS	El Paso, TX
Nellis Air Force Base	VA Southern Nevada HCS	Las Vegas, NV
David Grant Medical Center	N. California VAHCS	Fairfield, CA
Kirkland Air Force Base	New Mexico VAHCS	Albuquerque, NM
Tripler Army Medical Center	VA Pacific Island HCS	Honolulu, HI
Elmendorf Air Force Base	Alaska VAHCS	Anchorage, AK
James A. Lovell Federal Health Care Center	James A. Lovell Federal Health Care Center	North Chicago

Source: Petzel, 2013.

The third type of DoD-VA collaboration is the Joint Incentive Fund project, which provides funding for pilot projects across the two departments. The intent is to incentivize innovative DoD/VA sharing initiatives at the facility, regional and national levels. Project proposals are selected from an annual call for proposals across VA and DoD. From 2003, when Congress established the Joint Incentive Fund, until 2012, 130 projects were funded at a cost of $418 million (GAO, 2012a). A 2012 GAO report indicated that this bottom-up process was likely insufficient to identify the full range of new opportunities for collaboration, and recommended more systematic investigation (GAO, 2012a).

3.4.3.2 Indian Health Service

VA and Indian Health Service announced a joint national agreement in 2012 under which VA agreed to reimburse Indian Health Service for direct care provided to eligible American Indian and Alaska Native Veterans. By July 2014, the two departments had completed 83 implementation plans, which establish processing and payment procedures at 108 health care facilities. VA also established 61 reimbursement agreements with Tribal Health Programs for tribally run health care facilities so that they can receive reimbursement for direct care services.

In FY 2014, VA reimbursed approximately $11.2 million to Indian Health Service and the Tribal Health Programs for direct care services, up from $6.2 million in 2013 (VA, 2015a).

3.4.3.3 Academic Medical Centers

Affiliation and sharing agreements with academic medical centers provide VA with internal capacity as well as external resources. Affiliations were initiated in 1946 in an effort to assist VAMCs in recruiting high-quality physicians and to provide training sites for medical school residents and students (Leeman & Kilpatrick, 2000). VA is now the largest provider of medical training in the nation, accomplishing this through affiliation agreements between 152 VAMCs and 130 of 141 accredited U.S. medical schools (VHA, Procurement and Logistics Office, 2014). Affiliation agreements are standard templates that may be subject to review by the VA Medical Sharing /Affiliate Office depending on the size and type of agreement. VA has recently moved these contracting activities from VAMC employees to VISN staff.

In addition to individual authorization for Veteran care at academic medical centers, VA enters into multiyear sharing agreements with academic medical centers to provide care inside and outside of VA facilities. There are three types of sharing agreements—those that are based on a specified number of hours logged by a provider at VA facilities, those that are based on the number of procedures that are performed either at VA facilities or off-site, and those that are based on the number of patients served either at VA or off-site (VHA, Procurement and Logistics Office, 2014). In FY 2007, VA had a total of 1,714 clinical sharing agreements, valued at $1.7 billion, with affiliated institutions, including medical schools and teaching hospitals. Of these, 669 were sole-source contracts, with a value of $575 million (VA, Office of Inspector General, 2008). In 2014, VA reported spending $1.17 billion under all clinical sharing agreements with affiliates and $185 million under noncompetitive affiliate contracts. We were not able to determine the breakdown of spending for direct care of Veterans and ancillary and support services or between care provided in VA facilities and care provided at academic medical centers.

3.4.3.4 FQHCs

As federally funded organizations, FQHCs are required to be located in medically underserved areas or to provide service to medically underserved populations. Given the large population of rural enrolled Veterans, FQHCs represent an important potential source of care. Providers at FQHCs may provide care to Veterans as a contracted CBOC, through individual authorizations, as part of specific contracted services, or that is not reimbursed by VA (Heisler, Panangala, & Bagalman, 2013). As an example of FQHC-contracted services, as of February 2012, VA had 52 contracts for FQHC-provided counseling services across 13 VISNS (Heisler, Panangala, & Bagalman, 2013). Through various actions, Congress has repeatedly encouraged VA collaboration with FQHCs, particularly for the care of rural enrolled Veterans (Heisler, Panangala, & Bagalman, 2013).

3.4.3.5   Community-Based Mental Health and Substance Use Clinics

In 2014, VA established pilot partnerships with 24 community-based mental health and substance use clinics in nine states. These partnerships were formed in direct response to Executive Order 13625 in 2012, which directed VA, DoD, and the Department of Health and Human Services to take the necessary actions to ensure that Veterans, service members, and their families receive needed mental health and substance use services and support (Department of Defense, Department of Veterans Affairs, & Department of Health and Human Services, 2013). VA initiated the pilots to determine how community partnerships could help provide mental health and substance use services in areas that have staff recruitment and/or wait-time issues for mental health and substance use services. Sites were selected based on recruitment issues, performance data, and a willingness to participate; they were funded for one year. The partnerships offer a range of resources, such as telemental health, staff sharing, and space utilization agreements to allow VA providers to provide care in the community clinics. VA is conducting an evaluation of the pilot projects to determine the impact on Veteran access, wait times, and experience with mental health and substance use care at the participating clinics.

3.4.3.6   Non-VA CBOC Operators

VA provides care to Veterans at 694 CBOCs,[39] which may be VA-owned and -operated, leased but staffed by VA personnel, or contracted sites in which the space is not VA owned and the staff are not VA personnel. In 2009, about 25 percent of CBOCs were contracted (Panangala & Mendez, 2010); the percentage contracted fell to about 15 percent in 2015. Some organizations may operate multiple CBOCs. As an example, a Humana subsidiary, Valor Healthcare, operates 21 CBOCs across the country. VA has also operated CBOCs in partnership with DoD facilities, Indian Health Service, and FQHC facilities. Under the standard VA contracts for CBOCs, contractors provide "health care staff, medical facilities, medical equipment, supplies, and all administrative functions sufficient to achieve the contracted level of care in a manner consistent with VHA standards" (Panangala & Mendez, 2010). VA also requires the contractor to utilize VA's CPRS for documentation of all patient-related care. VA pays its CBOC contractors a monthly capitated rate based on each enrolled patient. These payments are not included in the total purchased care spending of $7 billion for 2014.

3.4.4   Selecting a Purchased Care Program

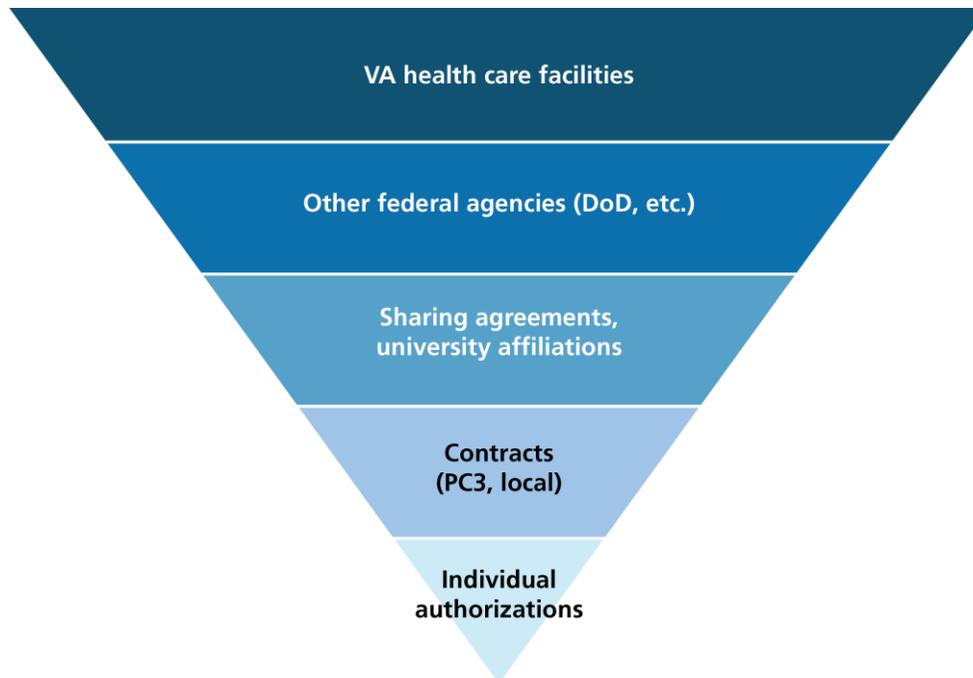
Prior to the implementation of the Veterans Choice Program, VA had an established hierarchy to guide VAMC decision-making about which program to utilize for purchased care (Figure 3.4-4). The first option is a VA facility, followed by care provided by other federal agencies, sharing agreements or university affiliations, PC3 or local contracts, and finally, individual authorizations. Interviewees indicated that compliance with this hierarchy is variable at the

---

[39] This count reflects the changes to the Veterans Affairs Site Tracking System definitions in March 2015. The total includes 509 primary care CBOCs and 185 multispecialty CBOCs.

---

local level. With the addition of the Veterans Choice Program, VA is working to update its guidance to VAMCs about selection of the appropriate program.

Figure 3.4-4. Hierarchy for Referrals to VA Purchased Care Programs


Source: Robinson, 2014.

3.4.5 Challenges in Utilizing Care Delivered by Non-VA Entities

Relations with external entities that provide care to Veterans represent an important resource for VA; however, stakeholder interviews, Veteran service organization testimony, and government reports all point to numerous challenges associated with utilizing purchased care. These barriers reduce the potential of this resource to provide timely and accessible care. Some of these challenges are discussed in more detail in the Assessment C report, but we provide a brief overview below and describe some ways in which VA is addressing the challenges.

3.4.5.1 Confusion About the Various Purchased Care Programs

The addition of the Veterans Choice Program further complicated an already complex system of authorities and purchased care programs and has created confusion among Veterans, VAMC staff, and providers. A survey conducted by the Veterans of Foreign Wars indicated that Veterans did not understand the eligibility criteria for the Veterans Choice program (Veterans of Foreign Wars of the US, March 2, 2015). VA has acknowledged gaps in employee and Veteran understanding of the program and related processes. To address these issues, VA has expanded its outreach efforts for Veterans and has developed employee trainings, named local "Choice Champions," and is developing documentation to support local decision-making on using the appropriate non-VA program. Community provider confusion stems from the fact that

providers may be referred Veteran patients through multiple purchased care programs, each of which may have a different reimbursement rate and documentation requirements.

3.4.5.2   Contracting Issues

In interviews, VA officials and experts indicated that contracts that VA negotiates directly with providers (not PC3 or Veterans Choice Program agreements) may take months to put in place and therefore reduce VA's ability to respond to local needs in a timely way and discourage non-VA providers from contracting with VA. One VA expert commented:

> In previous work I've done in interfacing with private facilities who've had to work with VA, a common refrain was that they would rather do the work for free than to deal with the painful VA contracting processes that typically take many months and is very resource intensive; it took more resources to execute a contract than just do the work and take care of the Veterans themselves.

As part of VA's FY 2016 President's Budget, VA asked Congress for legislative change to the current contracting rules to streamline the process of purchasing care when other options are not available.

3.4.5.3   Monitoring Access to and the Cost of VA Purchased Care

Historically, VA has not had the ability to track the wait times for Veterans to be seen by non-VA providers or the relative costs of VA and purchased care (GAO, 2013c). VA is beginning to monitor the timeliness of outside care through the implementation of the PC3 program as well as the Non-VA Care Coordination program. The Non-VA Care Coordination program utilizes VA personnel to schedule appointments with non-VA providers and document the wait time, among other things. However, VA has indicated to the GAO that it will not be able to monitor wait times for all purchased care until it completes a redesign of the claims processing system, which is expected in 2016 (Williamson, 2014). In its 2013 report, GAO also indicated that VA cannot assess the relative cost of purchased care due to an inability to analyze data on all services and charges for an episode of care. VA responded that it is working to improve its systems to enable this analysis but provided no timeline for implementation (Williamson, 2014). These challenges limit the effective use of this resource.

3.4.5.4   Information Sharing/Care Coordination/Fragmentation of Care

A lack of information sharing and coordination of care with non-VA providers is a problem that is not unique to VA; fragmentation of care and information sharing are issues throughout the U.S. health care system. As in the private sector, fragmentation can adversely affect the quality and cost of Veteran care, particularly as VA referrals to non-VA providers increase. In the 2016 Independent Budget, the authors described the Veteran experience under the traditional program:

> The IBVSOs [Independent Budget Veteran Service Organizations] believe VA has the obligation to lift the burden from Veteran patients who are bridging the fragmented and disconnected care VA buys from the private sector. Veterans are currently assumed to lead the sharing of information and communication between private providers and VA

> when receiving VA-purchased care, particularly through fee-for-service. (AMVETS, Disabled American Veterans, Paralyzed Veterans of America, & Veterans of Foreign Wars of the U.S., 2015, p. 177)

VA is attempting to improve coordination through information sharing requirements for PC3 and Veterans Choice Program providers and through the Non-VA Care Coordination program. However, health records are typically faxed from non-VA providers and scanned into the VA system, decreasing their utility. VA has piloted electronic health information exchange with DoD and private providers, and these efforts are discussed in Subsection 3.5.

3.4.5.5   Collaborations with DoD

A 2012 GAO report identified several key challenges in the collaborations between VA and DoD. First, the lack of interoperability in the IT systems impedes access to patient information. At some joint sites, workers even use two computers on the same desk to accommodate the incompatible systems. Although the two departments are no longer working on a common electronic health record, at some sites they are utilizing a software viewer that allows clinicians to jointly access health record systems. Second, the two departments use different business and administrative practices, including coding and billing systems, which can delay reimbursement. Different internal processes for provider credentialing and overlapping information security requirements also pose challenges for staff. For Veterans, gaining entry to military bases can be challenging. The entry requirements are designated by base commanders and may change over time to reflect the needs of the base. For Veteran patients, and people who accompany them to appointments, additional documents, entry delays, and background checks may pose barriers to site entry. Finally, VA and DoD do not have an aligned process for approving potential joint endeavors, so projects may not move forward when approvals and funding are on different timelines (GAO, 2012a).

3.4.5.6   Claims Processing Problems[40]

Problems with the accuracy and timeliness of reimbursement for purchased care may affect the willingness of providers to accept VA patients and thereby limit this important resource. Purchased care medical care claims processing has undergone intensive scrutiny by the VA Office of Inspector General, the GAO, and others and was found to need attention and improvement. The VA Office of Inspector General reports (2009 and 2010) documented hundreds of millions of dollars in erroneous payments or missed revenue collection opportunities. VA has been working to improve business processes through the consolidation of staff and funding for purchased care claims processing under the Chief Business Office and through audits of VISN efforts to improve the timeliness of provider payments. Additionally, care provided through the PC3 and Veterans Choice programs is reimbursed by the third party administrators rather than VA.

---

[40] Assessment I is addressing Business Processes, including claims processing.

3.4.6 Subsection Summary

Care provided to Veterans through relations with non-VA entities represents a substantial and growing resource for VA. Care is provided to VA enrollees by non-VA providers through several programs and various types of payment or contractual arrangements that VA has negotiated with its partners. Preauthorized programs include individual authorizations; care obtained through partnership agreements between VA and DoD, Indian Health Service, and other entities; the ARCH program; the PC3 program; and the Veterans Choice Program.

Managing this resource has proven challenging. As VA was attempting to address some of the administrative challenges associated with arranging, coordinating, and reimbursing purchased care through the implementation of the PC3 program, the addition of the Veterans Choice program further complicated the situation and resulted in confusion among Veterans, VA employees, and non-VA providers. Both the PC3 and Choice programs have been underutilized relative to VA projections, and the PC3 program did not achieve the savings expected in 2014. In fact, care provided through the PC3 program cost more than it would have cost VA to purchase the care through individual authorizations due to the overhead costs, according to the VA Office of Inspector General. In addition, VA has not had the ability to track the wait times for Veterans to be seen by non-VA providers or the relative costs of VA and purchased care. VA also faces a lack of information sharing and coordination of care with non-VA providers, which can be detrimental to quality. Collaboration with DoD has also proved challenging and has limited the opportunities for gaining efficiencies through the sharing of resources.

VA and members of Congress have expressed a desire to more effectively utilize this important resource as demand increases. VA has been working to improve business processes through the consolidation of staff and funding for purchased care claims processing and through audits of VISN efforts to improve the timeliness of provider payments and has asked for changes in the law to allow a more streamlined contracting process. It is also working with the third-party administrators and VA staff to attempt to increase utilization of the PC3 and Choice programs.

In the next subsection, we take a closer look at VA IT resources (computing hardware, peripheral devices, software), which are used to support a wide range of capabilities that affect the ability of VA to deliver timely and accessible care.

3.5 IT Resources

IT resources (computing hardware, peripheral devices, software) support a wide range of capabilities that affect the ability of VA to deliver timely and accessible care. VA IT is being examined in detail in Assessment H from the strategy and management perspectives, and Assessment E will cover IT related to scheduling systems, so we have focused Assessment B on the IT resources that support a set of six IT capabilities that directly impact Veteran access to care:

- Telehealth: the use of technologies to provide clinical care when distance separates patients and providers

---

- MyHealtheVet: a patient portal that Veterans can use to perform actions such as downloading their medical record, sending messages to their providers, and refilling prescriptions

- Mobile applications: software that Veterans can use to monitor their health from their smartphones

- VistA/CPRS: VA's IT platform for patient records and clinical care and the graphical user interface for the electronic health record system

- Data exchange between local VA systems, with DoD, with private-sector providers, and directly with patients

- Care management: programs, often facilitated by IT, that attempt to proactively provide care for patients with the goal of improving outcomes and saving costs.

This subsection describes the types and extent of VA resources that support each capability, how they can be used to improve timely and accessible care for Veterans, variation in current use within VA, comparisons with non-VA organizations, and barriers to expansion.

A summary of the methods used in these analyses is shown in the box.

Overview of Methods and Data for Assessment of IT Resources

- To identify IT resources and capabilities, we conducted a targeted review of the academic and gray literatures, focusing on six capabilities identified as most relevant to Assessment B: telehealth, MyHealtheVet, mobile applications, data exchange, core electronic health record functionalities, and care management.

- We used interviews with stakeholders internal and external to VA (conducted by our team, the qualitative team, and Assessment H) to address the mechanisms by which the capability may affect timely and accessible care to Veterans, VA's resources and capabilities to use the capability, and barriers to expanding use of and improvements to the capability. We also reviewed the academic literature and gray literature, including VA publications supplied to us by key informants, from 2010 to the present.

- Additional data concerning access to IT, use of IT, and usability and user satisfaction were obtained from the VHA Support Service Center.

- For complete details of the methods used to assess IT resources, please refer to Section 2 of this report.

3.5.1 Telehealth

VA defines telehealth as the use of technologies to provide clinical care when distance separates patients and providers. The main objective of telehealth is to increase access by bringing the full breadth of VA care to locations where these services do not exist (for example, rural outpatient clinics, Veterans' homes). The roles of telehealth in expanding access to care in VA are further discussed in Appendix E. Telehealth has been a focus for VA for more than a decade, and VA is now recognized as a world leader in this area, with no other delivery system offering such an extensive range of telehealth services at such a large scale.

3.5.1.1 Current Telehealth Utilization

Telehealth within VA consists of three modalities: clinical video telehealth, store and forward telehealth, and home telehealth (Table 3.5-1). We will describe primarily the first two in this subsection because home telehealth will be discussed in the context of tools for care management in Subsection 3.5.6.

The resources required vary considerably depending on the modality and the service line (for example, specialty care, primary care); however, clinical video telehealth programs generally require equipment (for example, telehealth cart with or without peripherals to support a physical examination), a consulting clinician at the remote site (for example, VAMC), an assisting provider and/or telehealth clinical technician at the patient's site, Internet bandwidth sufficient to support two-way transmission of video or other modality, and dedicated space at both the remote and patient sites.

Table 3.5-1. Telehealth Definitions

Modality	Description	Objective
Clinical video telehealth	Use of real-time interactive video conferencing, sometimes with supportive peripheral technologies, to assess, treat and provide care to a patient remotely. Typically, clinical video telehealth links patient(s) at a clinic to provider(s) at another location; however, it can also connect a remote provider and a patient at home.	▪ Provide access to specialists practicing in regional medical centers ▪ Reduce travel burden for Veterans in remote or underserved areas
Store-and-forward telehealth	Use of technologies to acquire and store clinical information (for example, high-resolution images, sound, and video) that is then made available to a provider at another location for clinical evaluation. It is frequently used in radiology, dermatology, and diabetic retinopathy.	▪ Provide access to specialists practicing in regional medical centers ▪ Reduce travel burden for Veterans in remote or underserved areas
Home telehealth	Applies care and case management principles to coordinate care using health informatics, disease management, and technologies such as in-home and mobile monitoring, messaging, and/or video technologies.	▪ Facilitate continuous (non-episodic care) to improve clinical outcomes ▪ Provide acute and chronic care management, and promote health and disease prevention

Sources: Darkins, 2013, and "VA Telehealth Services" at http://www.telehealth.va.gov/.

According to VA data, 690,000 Veterans (approximately 12 percent of VA enrollees) utilized one or more telehealth modalities in FY 2014, engaging in more than 2 million telehealth visits (VA,

2014f). Telehealth use has grown rapidly in recent years. For example, 380,000 unique Veterans participated in store-and-forward visits in 2014 compared with 311,000 the year before, and approximately 250,000 patients used clinical video telehealth between VA clinics in 2014 compared with 203,000 in 2013. In 2014, 4,000 Veterans received clinical video telehealth visits directly into their homes versus 2,250 in 2013. In FY 2014, VA's Office of Rural Health alone funded a set of initiatives that saved rural Veterans approximately 8 million miles in travel, representing 38 miles saved per telehealth visit. This represents a small piece of the overall impact of telehealth for patients in VA, including increased convenience and reduced time and travel costs. In recent years, telehealth has expanded to cover 45 specialties. Detailed operations manuals now provide specific guidance for several clinical telehealth services including Telemental Health, TeleDermatology, TelePrimary Care, TeleAudiology, TeleRehabilitation (including amputation care), TeleNutrition, TeleWomen's Health, and TeleRetinal Imaging. More than 11,406 VA staff members are trained annually to build competencies related to the business, clinical, and technology aspects of all three modalities, according to VA staff.

While telehealth is used in a wide range of clinical areas, a few types of encounters account for the majority of utilization. In 2014, four types of encounters accounted for more than 50 percent of all clinical video telehealth encounters: mental health, MOVE! Weight Management Program (a weight management program), clinical pharmacy, and primary care medicine. Three encounter types accounted for 98.9 percent of all store-and-forward telehealth encounters: diabetic retinal screening, electrocardiography, and dermatology (Table 3.5-2) (Telehealth Cube, VSSC, 2015d). The facilities survey conducted in coordination with this assessment found that among five specific clinical conditions (PTSD, SUD, TBI, colon cancer, and type 2 diabetes), clinical video telehealth between provider and patient was the most widely used telehealth modality. According to survey respondents, this was usually conducted with a provider in a VAMC (77 percent of the time) and patients at a CBOC (67 percent of the time, the patient was at a small or medium CBOC). However, some patients at VAMCs were on the receiving end of clinical video telehealth as well.

Table 3.5-2. Number of VA Telehealth Encounters by Type, 2014

Encounter Type	Number of VA Telehealth Encounters
Clinical video telehealth	
Mental health clinic	374,919
MOVE! Weight Management Program Group*	142,984
Clinical pharmacy	69,507
Primary care medicine	52,689
Psychiatry	51,642

Encounter Type	Number of VA Telehealth Encounters
PTSD clinical team	31,745
Audiology	31,476
Mental health integrated care	28,633
Nutrition/dietetics	28,238
Anti-coagulation clinic	26,264
Diabetes	23,351
Mental health clinic group	21,597
Psychology	20,728
Substance use disorder group	19,793
Physical therapy	15,511
Store-and-forward telehealth	
Diabetic retinal screening	424,485
Electrocardiography	185,816
Dermatology	129,823
Cardiology	3,226
Pulmonary function	2,716

Source: VA, 2015d.

Notes: "MOVE! Weight Management Program Group" is a national weight management program. Encounter types are defined by VA using "stop codes," which are internal VA codes that categorize encounters by the site and/or type of care delivered.

Veterans report very high levels of satisfaction with these widely used telehealth services. Surveys of Veterans in 2013 found that 94 percent were satisfied with clinical video telehealth, 95 percent with store-and-forward telehealth, and 84 percent with home telehealth (VA Telehealth Services Fact Sheet, FY 2014c). Furthermore, a 2014 survey of 11,000 clinical video telehealth users found that 88 percent preferred telehealth to traveling a long distance to see a provider (VA, 2015a).

3.5.1.2   Telehealth Use Outside VA

Comparative data on telehealth use from outside VA are limited because there are few organizations using telehealth at a similar scale. Where comparative data are available, it is clear that VA is delivering more care and a greater range of services via telehealth than private-sector organizations. The federal Indian Health Service is also widely implementing telehealth,

but no publicly available data describe the full extent of its reach. VA and the Indian Health Service are in a unique position to set the industry standard, in part due to their ability to structure services based on their institutional missions with fewer concerns about the impact on revenue than fee-for-service health systems. VA also has fewer barriers to telehealth (such as state medical licensing requirements) than the private sector. Next, we describe telehealth usage for several public and private-sector organizations that have published data on this topic.

Kaiser Permanente: Kaiser Permanente in Northern California reported that the number of virtual visits (including email, telephone, and video) for its 3.4 million members grew from 4.1 million in 2008 to 10.5 million in 2013. Kaiser has not independently reported the number of video visits, but expects them to surpass the number of in-person office visits by 2016 (Pearl, 2014).

Indian Health Service: Although we could not identify any literature on the full extent of the Indian Health Service's telehealth use, the Indian Health Service is aggressively pursuing telehealth because Indian Health Service and tribal health care facilities are predominantly in rural and isolated settings with little access to specialty services, and travel costs to bring patients to specialists are prohibitive. As one example, the Alaska Federal Health Care Access Network has been installed in 250 sites throughout Alaska. In 2013, 1,686 clinicians used this system to deliver 36,229 episodes of care for 22,982 patients—16 percent of all Alaskan natives (Hays et al., 2014).

Medicare: In 2009, fewer than 14,000 Medicare beneficiaries (of approximately 8 million eligible due to their rural location) engaged in 38,000 telehealth visits. As such, telehealth reached approximately 0.2 percent of the eligible population in that year. Of the 38,000 telehealth visits, 62 percent were for mental health services: pharmacological management (47 percent), individual psychotherapy (8 percent), and psychiatrist diagnostic interview examinations (7 percent). Almost one-third were office and other outpatient visits, and 5 percent were end-stage renal disease consultations (Gilman & Stensland, 2013).

Department of Defense: The DoD National Center for Telehealth and Technology oversees projects related to mobile health, telehealth, and other emerging technologies. Within DoD, the Army conducted approximately 36,300 encounters in FY 2013, the majority of which involved soldiers in garrison. The Center provides resources for active-duty soldiers, reserves, and their families. The Army's telehealth program covers 28 different specialties, but it focuses heavily on behavioral health: Tele-behavioral health accounts for 85 percent of the total telehealth volume in garrison and 57 percent in operational environments (Bloch, April 16, 2014). Virtual care is provided through various means, including a telephonic nonmedical counseling program as well as the mobile applications described below, some of which are developed jointly with VA (National Center for PTSD, 2014). The Air Force and Navy have some of their own programs as well as some joint efforts, for example, tele-critical care, tele-behavioral health, and provider-to-provider tele-consultation in the Pacific (Bloch, 2014).

3.5.1.3   Telehealth Innovation

While VA continues to refine and expand its traditional telehealth offerings, it also regularly develops and tests potential innovations. For example, clinical video telehealth was introduced

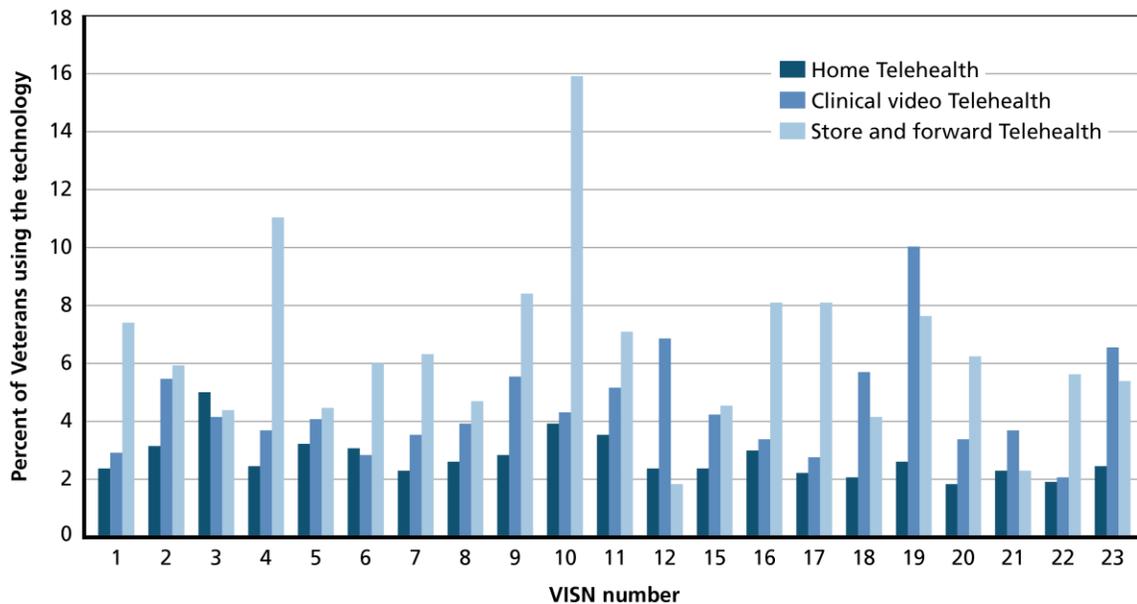
in 2002, but VA is expanding telehealth to serve patients in their homes rather than telehealth-enabled clinics. Piloted in 2012, this program allowed 2,248 Veterans to receive secure encrypted video consultations in their homes and on their personal computers by 2013. A year later, the number of Veterans served by this program nearly doubled to 4,000 (Darkins, 2014; VA, *VA Virtual Health Care Access Presentation*, 2015). While the program is adding eligible Veterans each month, a number of barriers exist to its further expansion. Interview participants noted that various program requirements, such as the need for Veterans to have their own webcams and high-speed Internet, are significant barriers to participation. A 2013 survey of Veterans found 70 percent accessed the Internet, but 8 percent of these Veterans had only a dial-up connection (ICF International, 2013; VA, 2013b). Furthermore, interview participants explained that Veterans drop out of the program due to lack of technical support, as the national telehealth help desk cannot talk directly to patients to resolve their IT challenges.

Other examples of innovative pilots identified by interview participants included the Telehealth Intensive Care Unit (TeleICU), Telewound, and teleanesthesiology. TeleICU connects VAMC ICU staff with TeleICU central monitoring center staff for real-time interaction and patient monitoring, which especially benefits VA's ICU patients in rural and smaller VAMC ICUs that may be understaffed (VA, 2014a). Telewound, on the other hand, is an example of store-and-forward telehealth. According to one interview participant, six VISNs were recently given funding to implement programs in which images of wounds would be sent to a wound care technician to help guide the treatment process at a remote location. Finally, in teleanesthesiology, Veterans who previously saw multiple providers for pre-operative care can now go to a CBOC and see both a nurse and an anesthesiologist via clinical video telehealth in a 45-minute period.

3.5.1.4 Geographic Variation in Telehealth Use

While telehealth is widespread in VA, use varies considerably across regions and populations. VA has released statistics demonstrating that telehealth reaches rural Veterans preferentially, which aligns with VA's goals to increase access to the underserved. While rural Veterans constitute 30 percent of the Veteran population, they represented 45 to 55 percent of all telehealth users in 2013–2014 (Peterson, 2014; VA, 2014f).

However, internal VA data suggest considerable variation across VISNs in the percentage of Veterans who accessed telehealth in FY 2014 (Figure 3.5-1). For example, the percentage of unique patients that used one or more modality in a given VISN varied from 8 percent to 22 percent.

Figure 3.5-1. Percentage of Veterans Using Telehealth Modalities by VISN, FY 2014


MS4675B-3.5-1

Source: Telehealth Cube (Virtual Care Modality, FY 2014 data), VSSC, 2015.
Notes: VISNs 13 and 14 do not exist. City hubs associated with each VISN are listed in Table 3.1-3.

The geographic reach of telehealth encounters is fairly limited because VISNs primarily serve patients in their own regions. In 2014, 99 percent of telehealth visits (clinical video and store-and-forward) were delivered within VISNs rather than across VISNs, with only six VISNs providing telehealth consults to 10 or more other VISNs. VISNs 1, 11, and 19 had the largest proportion of their total telehealth visits with patients in other VISNs (a range of 3–7 percent) (VA, 2015b). VISN 19, for example, provides genetic counseling services via telehealth to patients across VA. The fact that telehealth is a relatively localized phenomenon may represent a missed opportunity for load balancing across the VA system.

Interview participants identified several reasons why VISN-to-VISN telehealth is not more widespread. First, staff at a given VAMC may not know which VAMCs outside of their VISN have extra capacity and what services are offered. Second, VISN-to-VISN telehealth has negative implications for workload credit. "When you have a local provider and patient you get credit for one visit. When you are connecting to another facility outside your VISN, you get a 0.5," one participant explained. Finally, there is a shared understanding that, as a training institution, each medical center must have its own capabilities. According to another interview participant:

> Part of VA is doing education and you don't want to take educational opportunities away, so for things that are pretty basic…you want to provide that care at the local site if you are a teaching hospital, so we can't lose sight of that. You can't say that hospital A is going to do cardiology for everyone because

hospital B and C also have cardiology programs that need to support their residency programs.

Just as there is limited use of VISN-to-VISN telehealth, relatively few Veterans are accessing telehealth from non-VA sites, such as non-VA medical facilities. Greater use of non-VA sites would offer additional convenience for Veterans and further increase access in communities where VA has limited or no presence. Of the approximately 250,000 Veterans who used clinical video telehealth in 2014, only 0.3 percent were at non-VA sites other than their homes. Interview participants mentioned several sites with which their VAMC clinicians currently connect, including non-VA hospitals and long-term care facilities, universities, and prisons; they also acknowledged that non-VA sites are underutilized and their use should be expanded.

3.5.1.5 Barriers to Greater Use of Telehealth

VA performance measures currently address the proportion of Veterans using any form of virtual care (for example, telehealth, secure messaging, and e-consults) as well as one or more modalities of telehealth. In FY 2015, VA's target is to have 16 percent of unique Veterans using the three types of telehealth.

Although telehealth has grown rapidly, its growth has fallen short of VA targets, reaching 11–12 percent of Veterans in 2013 and 2014. This led VA to survey VISNs and VHA Telehealth Services in summer 2014 regarding barriers to telemedicine use. VA found that the leading barriers were insufficient space for telehealth, inadequate Office of Information and Technology and Biomedical Engineering infrastructure and support, lack of leadership/provider buy-in, and insufficient staffing resources. Our interviews largely confirmed these findings, with a few minor differences. Interview participants did not independently identify insufficient staffing resources as distinct from provider buy-in; however, in a few instances they described problems filling the position of CBOC telehealth clinical technician. Interview participants also placed greater emphasis on insufficient bandwidth at CBOCs. Below we describe each leading barrier in greater depth.

Insufficient space for telehealth. According to VA internal analyses, "New services that can be provided at CBOCs where they did not exist before, such as TeleAudiology, TeleRetinal Imaging, and TeleCardiology, require a clinical room or space for the patient to be able to connect via video to the provider at the remote site. Therefore, new telehealth clinics compete with space created for and currently used for in-person primary care visits." Interview participants also echoed this concern, explaining that "there are major space constraints at CBOCs" and "telehealth and face-to-face care are in constant competition for space." As one interview participant explained, "Telehealth really got started in 2012, and by that time, other specialties were already there. Everyone had to find one room for telehealth, but that is often all we have."

Inadequate Office of Information and Technology and Biomedical Engineering infrastructure and support. As VA is currently organized, the Office of Information and Technology is responsible for IT assets and resources across VA, while clinical devices and their associated computer hardware are managed by Biomedical Engineering, which is under VHA but separate from other VHA technology programs. As a result, while programs like MyHealtheVet and many

---

telehealth services are managed within VHA, the Office of Information and Technology or Biomedical Engineering may provide technical support. According to VA's internal assessment of barriers to telehealth, "VISNs have reported that the decentralization of Office of Information & Technology and Biomedical Engineering; the interdependent yet uncoordinated relationship between them; and the lack of national guidance for clarity on roles and responsibilities, have all contributed to issues with coordination and communication which has impeded the expansion of Telehealth services" (VHA Telehealth Services, 2014).

Interview participants referenced the same challenges, focusing specifically on difficulties engaging with the Office of Information and Technology to obtain resources and support. One specific complaint from multiple interview participants focused on Internet bandwidth: particularly at rural CBOCs, interviewees described insufficient bandwidth as a barrier to clinical video telehealth visits. At the same time, concern about bandwidth was not universal; several interview participants said this was a problem in the past but has largely been resolved. VA analyses also point out that while VA staff perceive existing bandwidth to be a problem, the extent to which it is problematic in practice is unclear. According to VA internal analyses:

> Although IT bandwidth capacity has been raised as a central issue by VISNs, the Office of Information & Technology has completed an analysis which showed that 1.1 percent of circuits have reached an 80 percent capacity/utilization threshold (75 out of 6,565). The Office of Information & Technology states that 96 percent of data circuits run at less than 60 percent utilization on average, with a median utilization of 20 percent.

As the VA report states, "It is not clear yet whether bandwidth is truly a limiting factor," or whether it is perceived as such because sites do not know to request additional bandwidth or do not receive it when needed. Interview participants expressed many challenges with the Office of Information and Technology, including that the regionalization has created a gap between assessment of requirements and managing bandwidth and performance to meet those needs. Communication gaps between VAMCs and the Office of Information and Technology are addressed in Assessment H.

Lack of provider buy-in. Clinicians who were interviewed expressed mixed views about telehealth. While some regularly provided telehealth visits within their VISN, others said they lack the capacity to add another service. As one clinician said, "I can tell you that in cardiology we're not ready for [telehealth] because it is adding a service where physicians are already stretched and it's not an efficient service. It is not like you'd be able to see more patients because it is more efficient. It would just be more patients and harder on you." Front office and administrative staff noted that providers are more likely to engage in telehealth in facilities "where leadership holds clinical staff accountable" and where telehealth use is incentivized. At the time of this report, VA as a whole has no specific performance measure or policies that require providers to offer telehealth. One interview participant explained: "Some have tied in performance pay for providers. This happens sporadically, on a service-by-service basis, not at the facility level."

Other barriers. Although these are the most significant barriers that interview participants identified, it is not an exhaustive list. Select interview participants highlighted burdensome

business rules with respect to credentialing and privileging, and complexities related to scheduling (both discussed in more detail in Assessment H). Interestingly, no interview participants cited patient acceptance as a major barrier. Although interview participants acknowledged that "telehealth is not for everyone," the consensus was that most Veterans— even older Veterans who may not be familiar with the technology—are accepting of telehealth. According to one clinician, "Patients like it. They say anything they can do through . . . they call it the TV . . . helps them. If they don't have to get on the road, they like it."

3.5.1.6   A New Form of Telehealth: e-Consults

A promising new form of telehealth is e-Consults, which has been spreading to more VA sites. These electronic consults allow primary care physicians to contact specialists who review the patient record and respond with treatment advice or recommend an in-person visit. Providers submitting requests for e-Consults to local specialists are instructed to use the feature only for non-emergent issues, and specialists are expected to respond within three business days. Because the request process occurs within CPRS, relevant medical records, lab results, and other test results are available to the consultant via the electronic health record (McAdams, Cannavo, & Orlander, 2014).

In interviews, primary care physicians have praised the potential of e-Consults as a fast and easy way to increase efficiency of provider communication (Zuchowski et al., 2015). Early survey results show very high rates of satisfaction among primary care physicians (93 percent satisfied) and patients, with lower satisfaction rates for specialists (53 percent satisfied). A 2010 survey found similar results, with primary care physicians and Veterans very satisfied (median of 5 on a 1–5 scale) and specialists reporting slightly less satisfaction (3.5) (Rodriguez et al., 2015). Specialists were concerned that e-Consults did not decrease the utilization of face-to-face visits, though more agreed that the program increases quality of care. Researchers concluded that in some cases e-Consults eliminate the need for a face-to-face visit, thereby reducing patient travel and copays. When an e-Consult does not eliminate the need for a face-to-face visit, it can still increase appropriate pre-visit diagnostic testing or treatment adjustments, improve care coordination, and reassure the patient's primary care physician (McAdams, Cannavo, & Orlander, 2014).

In 2014, VA Central Office updated its policy to allow three levels of workload credit for e-Consults based on time spent responding to consults, a move that may increase specialist satisfaction. The authors conclude that the program seems to meet the goal of "using telehealth to improve Veterans' access to specialty care and coordination of care between [primary care physicians] and specialists."

3.5.2   MyHealtheVet

MyHealtheVet is a patient portal available to all Veterans who have Internet access and have been properly authenticated by VA. Users can download their medical record and send secure messages to their providers concerning clinical questions and prescription refill requests. To prevent fraud, VA has required in-person authentication following online registration to validate the patient's identity before they can gain full use of the services.

As of March of 2015, a total of 3.2 million people had ever registered for MyHealtheVet since its inception in 2004. 1.86 million have gone through the in-person authentication process and 1.2 million have opted to use secure messaging. As illustrated in Table 3.5-3, a large proportion of this activity has occurred within the past five years. 2.1 million Veterans, providers, and family members have registered since 2010 and the number of logins recorded since then has an average yearly growth rate of 48 percent. In addition, the rates at which patients have chosen to authenticate and use secure messaging demonstrate increased adoption: by 2014, secure messaging grew by 150 times compared with 2010, and in March 2015, almost 1 million messages were exchanged between providers and patients, according to internal VA records.

Table 3.5-3. Growth Trends in the Adoption and Use of MyHealtheVet, 2010-2014

Fiscal Year	New Registrations	New Authentications	VA Patients Opting-In for Secure Messaging	Unique Registrants Logging In	Total Logins	Total VA Patients
2010	240,300	83,700	2,300	569,900	6,199,600	6,000,110
2011	349,500	193,900	100,900	778,200	9,349,200	6,166,191
2012	497,000	470,300	375,600	1,122,100	16,419,400	6,333,091
2013	535,700	439,100	312,600	1,353,700	22,913,400	6,484,664
2014	513,900	382,400	300,700	1,537,500	28,755,200	6,616,963

Source: Internal VA data and Bagalman, 2014.

The use of secure messaging is also increasing, with VA patients or their health care team initiating 39 percent more messages in FY 2015 than in a similar period in 2014 (VA, 2015a). Secure messaging has been associated with fewer urgent care visits (Shimada et al., 2013), suggesting that increased use could free up resources and ultimately improve access to in-person care. One interviewee noted that a recent evaluation found that just 11.6 percent out of 1,000 secure messages contained questions on health issues, while around 55 percent requested services that could be covered by registered nurses or pharmacists such as medication refill requests and scheduling questions.

MyHealtheVet use varies widely across VA facilities and VISNs. The cross-sectional MyHealtheVet study of 6 million Veterans described above (Shimada et al., 2014) reported registration rates ranging from less than 10 percent to almost 35 percent of patients seen at the facility. Authentication rates ranged from three percent to 30 percent of patients. There is also wide variation in the use of secure messaging at the VISN level, ranging from less than 17 percent to 37 percent of unique Veterans receiving care at VA (excluding pharmacy) in FY 2014 (authors' analysis of VSSC data). Facilities with volunteers or computers on-site to help Veterans register and use the tool had higher rates of MyHealtheVet uptake (Shimada et al., 2013). Patient demographics influenced the likelihood of uptake as well—those using MyHealtheVet were more likely to be younger, white, female, and more affluent. Uptake also

varied with diagnosis, with higher uptake among those with trauma-related or mental health diagnoses, human immunodeficiency virus, hyperlipidemia, and spinal cord injuries (Shimada et al., 2014).

A new feature of MyHealtheVet is access to full medical notes written by clinicians, allowing Veterans to better understand their care, correct errors, and improve engagement. After a successful pilot in which researchers found that "Viewing their records appears to empower patients and enhance their contributions to care" (Woods et al., 2013), VA in 2013 made clinical notes available through MyHealtheVet, including outpatient primary care and specialty visit notes, discharge summaries, and emergency department visit notes (VA, 2013a). A survey of early adopters found that a majority of the users of VA's version, called VA Notes, agreed that "accessing their notes will help them to do a better job of taking medications as prescribed (80.1 percent) and be better prepared for clinic visits (88.6 percent)" (Nazi et al., 2014).

Secure messaging use has been included in VA performance measures; VA's 2013–2015 Strategic Plan for National Telehealth Services aimed to reach 50 percent of Veterans using virtual care (VA, Office of Patient Care Services, 2012). Given a projection of telehealth being able to reach 16 percent of Veterans, secure messaging and other tools like e-Consults would have to reach 34 percent to reach the 50 percent target. As described above, use has been increasing, and while some facilities have reached this 50 percent target, no VISN has. VA reports 32 percent use overall of any virtual care modality in FY 2014 (VHA Support Service Center Capital Assets, 2014).

Frequent surveys of MyHealtheVet users suggest that they are happy with the tool. At least 75 percent expressed satisfaction with a number of aspects, including content, functionality, look and feel, and site performance (VA, 2015b). Providers mentioned that it has facilitated their ability to address lower-risk issues or tasks since many patients utilize email and "electronic communication is a huge time saver" compared with other means such as the telephone.

However, there are barriers to further expanding the use of MyHealtheVet. VA employees we interviewed noted that in addition to the administrative burden on users of registering for MyHealtheVet, issues with the technology have hindered broader adoption. Veterans must have Internet access if they want to use MyHealtheVet, and a 2013 survey found that 30 percent of Veterans do not access the Internet. This is particularly an issue for rural Veterans, who are less likely to have Internet access; internal estimates from 2013 suggest that while 68 percent of urban Veterans report Internet access, only 59 percent of highly rural Veterans do. Interviewees also noted that Veterans with access to their medical information do not necessarily understand the clinical information in their MyHealtheVet profile.

Providers suggest that this confusion may require additional consultations or secure messages to explain the data. However, this issue may be mitigated by proxy access, which is in the process of being implemented. This will let a Veteran give a spouse or caregiver access to a MyHealtheVet account in their own name, rather than using the Veteran's login credentials. Lastly, the literature has noted navigability, readability, and other usability issues (Haun et al., 2014); an upcoming redesign is intended to improve ease of use.

In addition to these hurdles for patients, providers also face barriers that decrease their willingness to use the system, including a lack of integration with other clinical data systems. Providers use one electronic system for clinical documentation, but they need to enter a separate system to access secure messages. This lack of integration is partly by design due to security concerns and partly due to technical limitations, though there is awareness and desire for better integration of all virtual care systems on the part of many staff and leaders we interviewed. The OneVA program[41] may be the beginning of this integration attempt; interviewees told us that the Federal Emergency Management Agency Chief Information Officer will be taking a role in leading integration as well.

Providers also cited time burdens associated with answering secure messaging as a barrier to using MyHealtheVet, claiming they were not credited for their time using the tool. Even though office staff handle many of the messages, such as refill requests and appointment scheduling, the tool requires a lot of physician time. However, these concerns seem to have been heard by administrators, who have begun rolling out a "secure messaging workload credit" in an effort to increase provider use and satisfaction. They also plan to improve categorization of messages in the upcoming MyHealtheVet redesign so that messages are routed appropriately.

Patient portals "have the potential to improve both quality and access to care" (Emont, 2013). Evidence shows they can increase care efficiency and productivity, decrease the volume of phone calls and visits, improve chronic disease management, and engage patients. In addition, portal usage can create cost savings due to fewer phone calls, online scheduling, and other features (Emont, 2013). Other studies suggest that the benefits of these tools are limited to populations with the health literacy required to access and understand its features, which may enhance the educational and racial disparities in care for older Americans (Smith et al., 2015). Two recent systematic reviews, however, suggested that there are not enough data to show an impact of portals on medical outcomes (Goldzweig et al., 2013; Kruse, Bolton, & Freriks, 2015).

MyHealtheVet is similar to tools used by other major health care systems, though given the many contextual differences, direct comparisons are not possible. For reference, 62 percent of U.S. hospitals had a patient portal as of 2014 (Wise et al., 2015), and registration rates in each health group varied. For example, 25 percent of primary care patients at Geisinger registered with their portal as of 2011. Kaiser Permanente's portal registration reached 25 percent in 2009 (Emont, 2013) and was up to 73 percent by 2013. Kaiser Permanente's portal allows patients to choose a doctor, schedule appointments, view laboratory results, and order refills (Pearl, 2014). Satisfaction with the Kaiser Permanente tool is very high: 87 percent said in a 2013 survey that messaging with their doctor "did a very good or excellent job of meeting their needs." Kaiser Permanente also reported 2.3 million telephone visits in 2013, also with very high satisfaction results (Pearl, 2014).

---

[41] The OneVA Enterprise Architecture program's mission is to "serve as a strategic planning and management tool that helps VA's leadership chart the course for the Department's transformation into a 21st century organization." (http://www.ea.oit.va.gov/EAOIT/OneVA/EAOneVAEA.asp)

3.5.3   Mobile Applications

Mobile applications (apps)—software that Veterans (or anyone) can download and use from their smartphones to monitor their health—may improve access in many ways: assisting in self-help for people who do not need high levels of care, providing supplemental therapy in conjunction with care, and reducing stigma in seeking mental health support.

VA's Office of Connected Health has been rolling out apps for Veterans as well as providers. Media coverage has been enthusiastic:

> VA distributed over 10,000 tablets to clinicians across the country last year and launched a mobile app store with more than a dozen apps to provide Veterans with access to health services. The apps have been downloaded by more than 300,000 users since their release, according to VA officials (Jayakumar, 2015).

However, this article also notes that VA is "cautious," keeping the apps separate from electronic records and primarily using them to dispense general advice.

As of May 2015, 22 apps were available in the VA app store (https://mobile.va.gov/appstore), up from 11 in December 2014 (VA, 2014b). However, in interviews with VA leaders and health care providers, we found little use or even awareness of these tools. Chiefs of staff and medical directors were generally unable to discuss any apps actually used by patients or providers. While some were aware of an app store for Veterans, the use of mobile applications to engage Veterans with their providers appears to be limited.

Mental health is the clinical area with the greatest app use, with 11 different apps and many downloads (Table 3.5-4; we have not identified comparable download counts for the other 11 VA mobile apps). Most are self-help tools that can be used in conjunction with formal therapy. VA's first app was PTSD Coach, which has been downloaded 180,000 times in 85 countries and translated into several languages.

Table 3.5-4. VA Mobile Applications

App Name	Description	Launch Date	Countries	iOS Downloads	Android Downloads	Total Downloads
311VET	Allows Veterans to ask general VA Benefits questions and receive answers 24/7/365	May 20, 2015	59	2,280	1,077	3,357

App Name	Description	Launch Date	Countries	iOS Downloads	Android Downloads	Total Downloads
ACT Coach	Connects Veterans to a provider for acceptance and commitment therapy	Feb 5, 2014	56	4,685	n/a	4,685
CBT-i Coach	Used in cognitive behavioral therapy for insomnia	Jun 5, 2013	80	30,080	11,515	41,595
Concussion Coach	A resource to treat concussion or mild TBI symptoms	Nov 18, 2013	64	4,390	n/a	4,390
CPT Coach	Helps treat PTSD through cognitive processing theory	Feb 6, 2014	49	5,121	n/a	5,121
Exposure Ed	Provides information on military-related exposures to health care providers	Jan 13, 2014	20	2,500	n/a	2,500
Imaging Viewing Solution	Allows VA clinicians and other relevant staff to view patients' X-rays and other stored images	NA	NA	NA	NA	NA

App Name	Description	Launch Date	Countries	iOS Downloads	Android Downloads	Total Downloads
Mindfulness Coach	Resources to help a Veteran practice mindfulness	Jan 31, 2014	75	13,787	n/a	13,787
MOVE! Coach App	A weight self-management app	Nov 18, 2014	43	4,660	n/a	4,660
Moving Forward	Tools to learn problem-solving skills	Jan 31, 2014	47	2,588	n/a	2,588

PE Coach	Helps treat PTSD through prolonged exposure therapy	Mar 12, 2012	64	18,693	12,902	31,595
PFA Mobile	Tool for responders providing psychological first aid after a disaster	Aug 29, 2012	60	11,398	1,446	12,844
PTSD Coach	Resource for patients coping with PTSD	Apr 7, 2011	89	115,926	67,859	183,785
Stay Quit Coach	Tools to help Veterans who have quit smoking	May 30, 2013	64	4,620	n/a	4,620

HTML 5 applications (web-based, not downloaded):

HTML5 App Name	Description	Launch Date	Users	Total registered
Airborne Hazards and Open Burn Pit Registry (HTML5)	Online database of health information provided by Veterans and service members about exposures to airborne hazards	April 2014	64,039	41,555
Antibiogram App (HTML5)	Provides VA care team members with antibiotic resistance data	NA	NA	NA
Launchpad (HTML5)	A tool to access all apps that require a secure logon	NA	NA	NA
Mobile Blue Button (HTLM5)	Allows Veterans to access, print, and download information from the electronic health record	NA	NA	NA
Scheduling Manager (field test, limited audience) (HTML5)	Allows Veterans to receive and book appointment requests	NA	NA	NA
Summary of Care (HTML5)	Lets Veterans receive and view VA medical information	NA	NA	NA
Veteran Appointment Request (field test, limited audience) (HTML5)	Allows Veterans to request primary care and mental health appointments	NA	NA	NA

Sources: VA, 2015g, and internal VA communication, Office of Connected Health.

Note: NA indicates that the cell is not applicable because the app has not been nationally released.

None of these apps is integrated with electronic health records, though better integration is planned in the future, as noted above. One example is a new app called "MH PRO," through which mental health patient-reported outcomes from Veterans will be collected and integrated into the electronic health record. One interviewee suggested that this technology could be used in conjunction with telehealth, with Veterans completing a range of home exercises that would

normally be sent on paper via mail or fax, which would help providers obtain immediate feedback.

As a point of comparison, Kaiser Permanente, also a leader in health IT, provides more than 100 Internet, mobile, and video applications that allow patients to make appointments, access their health information, and exchange secure messages with their doctors (Pearl, 2014). However, most health care applications are created by companies, such as electronic health record vendors or other businesses, rather than health care systems, so VA is showing leadership in this effort.

VA mobile apps hold great promise to increase access to care, but due to limited functionality and requirements surrounding their use, there is little evidence that they have done so to date.

3.5.4   VistA/CPRS

VistA is VA's IT platform for all patient records and every aspect of VA operations related to clinical care (for example, clinical documentation, inpatient bed management, outpatient scheduling, supply inventory). VistA is developed and implemented locally; there are actually "126 different VistAs," one for each local health care system. While local facilities substantially develop their own modules and other customizations, they widely incorporate some of the approximately 200 separate modules/applications that VA certifies for national use (VA, 2013c).

CPRS is the graphical user interface to the electronic health record and the order entry system, the parts of VistA used by providers and nurses for day-to-day care of patients at their facilities. When released in 1997, CPRS was widely acknowledged to be innovative and the best in its class. Nearly 20 years later, it is still considered by many to have functionality on par with commercially available systems. However, previous reports have noted that little development has occurred over the past 10 years, and that both the underlying architecture and the functionality of the system are in danger of becoming obsolete (Veterans Health Administration Office of Health Information Product Effectiveness, 2012).

In 2012, VA conducted a comprehensive study of end-user perceptions of CPRS to identify its strengths and weaknesses (Veterans Health Administration Office of Health Information Product Effectiveness, 2012). The resulting report summarized the findings of 297 interviews with clinical and administrative personnel. While it made clear that a substantial number of respondents had a "positive impression of VistA and CPRS," particularly compared with their experiences with other electronic health record systems, it also identified a number of shortcomings, several of which might impede timely and accessible care.

One example detailed in the 2012 report was the existence of "shadow" scheduling systems:

> The project team heard from many participants who maintain 'shadow' scheduling systems using a myriad of programs. While these shadow systems may present a provider's calendar in an easily viewable format, these systems lack the security of VistA. This also creates the possibility of having multiple, incorrect schedules if the shadow schedule is not updated simultaneously when appointments are changed or cancelled.

. . . Several service areas use secured Microsoft Excel spreadsheets to schedule and track appointments. . . . Clinicians at one VAMC maintain paper records to track multiple providers' schedules across specialty areas.

This finding illustrates the centrality of VistA/CPRS to the provision of timely and accessible care. It might be said that the event that triggered the Veterans Choice Act (and this report) was facilitated by a culture of using unauthorized workarounds to make up for a VistA shortcoming (the lack of flexible and usable scheduling tools).

Other key areas for improvement identified in the 2012 VA report included the following:

- Non-intuitiveness of all but the most basic "paper chart equivalent" features
- Tools to support clinical workflow
- Nursing documentation tools
- Mechanisms for secure communication
- Clinical decision support
- Medication reconciliation at discharge
- Clinical reminders
- Alert fatigue
- Lack of a usable problem list functionality
- Lack of organizational or search functionality in "VistA Imaging"
- Inadequate cross-facility and remote access functionality
- Integration with other systems.

For this report, we interviewed CPRS end-users, IT engineers, and management personnel at local and national levels. Our findings were strongly aligned with those of the 2012 VA report: While nearly all shortcomings described in the previous report were also mentioned by current interviewees, there was also positive sentiment for certain CPRS design elements (for example, substantial use of free text), which were perceived to be "care-centric" rather than "billing-centric." Many noted that CPRS is rapidly losing ground to more modern IT systems, but few (if anyone) suggested that CPRS should be exchanged for a commercial off-the-shelf alternative. Many gave voice to the importance of an IT system designed for workflows unique to VA and to the needs of Veterans.

Interviewees noted three primary ways in which CPRS usability can negatively affect the provision of timely and accessible care: time burden of physician/CPRS interaction, faulty transmission and assimilation of information, and the lack of a mechanism for ensuring that future care occurs when it should.

3.5.4.1 Time Burden of Physician–CPRS Interaction

Inefficient tasks in CPRS (for example, unnecessary mouse clicks, unnecessary data entry, or unnecessary time spent assimilating information) mean more time spent with the computer and less spent addressing a patient's concerns. One notable theme to emerge from interviews

is that the inefficiencies with the greatest impact are perceived to be a result of policy decisions, rather than deficiencies in CPRS's functionality.

Central office management is strongly perceived as being overzealous in using CPRS to enforce clinical directives, mandate data collection, and measure compliance. The following quotes are representative:

> Performance measures have really gotten out of hand…Initially there were 10 clinical reminders that were really clinical and useful. . . . Now there are an excessive number. . . Many of these exist for the purposes of data collection. Some of the most onerous ones are unrelated to clinical care.

> We're cluttering up everything to the point that a provider can't work anymore because there's just too many things that you have to address regarding one patient, much of which has nothing to do with their health.

"Clinical reminders" were singled out as a mechanism by which a series of time-consuming patient interactions (and associated documentation) are mandated and compliance audited. Some estimated that a registered nurse or physician spends an average of 15–30 minutes of each visit responding to reminders. For example, one physician noted that he was required annually to ask any hypertensive patient with a body mass index in the "overweight" range whether the patient would like to enroll in an obesity reduction program ("MOVE"), whether or not the patient appeared obese, and whether or not the patient had previously declined. For diabetic patients, providers are required to document a "monofilament exam" to detect diabetic nerve damage at regular intervals, whether or not the patient was already known to have permanent nerve damage. For patients who say they are depressed (whether or not that is their primary reason for a visit), completion of a "suicide prevention reminder" reportedly can take 30 minutes to an hour. One interviewee said his patient went to the emergency room complaining of chest pain, and because he also indicated that he was depressed, "the nurses wanted to take care of the suicide reminder before doing the [electrocardiogram (EKG)]."

Some interviewees indicated that clinical reminders can sometimes be useful (for example, to trigger colon cancer screening). On the other hand, one reported that clinical reminders are not used for patient care at all at her facility because they are not considered reliable. She reported that providers relied on their own improvised systems to track clinically important information, and that responding to reminders was something done for the sake of managers. The between-system variation in the perceived value of reminders is consistent with reports that implementations of VistA/CPRS vary substantially, as does investment and expertise in tasks such as reminder development (Veteran's Health Administration, Office of Health Information Product Effectiveness, 2010).

3.5.4.2 Faulty Transmission and Assimilation of Information

Ensuring that providers use all relevant clinical information to make therapeutic decisions was highlighted as an important component of care access. For a patient to access appropriate follow-up care after an abnormal laboratory or radiology test, there must be a failure-proof mechanism by which an appropriate clinician in an appropriate timeframe sees and acts on the

results. More generally, it is important that each provider who treats a patient for a given constellation of symptoms has access to all elements of the evaluation (both objective data and subjective opinion) that occurred previously.

Interviewees identified several problem areas in this regard:

- **Clinical reports are "buried" in VistA Imaging.** VistA Imaging was developed as a module to store the image data from diagnostic tests (for example, X-rays, EKG tracings (Kuzmak & Dayhoff, 1998)). It is not part of CPRS although it can be launched via a web interface from CPRS. Increasingly, VistA Imaging has been used to store other clinically relevant information. At many facilities, it is the standard place to store scanned text reports of clinical evaluations or diagnostic tests obtained outside the VA system (VA, 2013c). If, for example, a Veteran is referred outside the system for a colonoscopy or ultrasound examination, the results typically are faxed to VA and stored on VistA Imaging. Because these reports are not indexed or searchable, the results might never be seen by a VA provider or incorporated into clinical care (Veterans Health Administration Office of Health Information Product Effectiveness, 2012). Even if one provider sees the report initially, lack of searchability means that others looking for the same information might overlook it.

- **Important information is obscured in an increasing volume of notes.** There is a perception that the number and length of notes has been increasing, in part due to mandatory documentation that is perceived to be of little clinical value. Copying and pasting old notes was also mentioned as a source of increased "noise" that reduces the visibility of important information. The "Where's Waldo" problem has been described as an inherent pitfall of electronic health record systems, not just CPRS (Hartzband & Groopman, 2008).

- **"Alert Fatigue."** Certain abnormal lab or radiology results can trigger automatic alerts to the providers that ordered them or to other personnel. Interviews suggest substantial variation across facilities. For example, at one institution, abnormal fecal occult blood tests are automatically routed to gastroenterology, where administrative personnel ensure that appropriate follow-up action is taken; at others, follow-up is the sole responsibility of the ordering provider. In general, clinicians feel overwhelmed by the number of alerts they receive and fear important ones are overshadowed by unnecessary "administrative alerts" that do not require clinical action.

3.5.4.3   Lack of a Mechanism for Ensuring That Future Care Occurs as Planned

Often, some combination of patient demographics, clinical history, symptoms, treatment guidelines, or provider judgment suggests that a particular type of care should occur at a specific time. For example, a radiologist might recommend a new chest X-ray in six months after an abnormality was found, or a clinician might want to repeat a laboratory test or reevaluate a patient's symptoms at some specific point in time. Several interviewees noted that CPRS lacks a mechanism for ensuring that such follow-up occurs and that, by and large, each provider is left to develop his/her own workarounds, such as using paper notebooks or electronic spreadsheets to track future plans, using the CPRS "problem list" in a way for which it

---

was not designed, and documenting "planned future care" at the end of each visit note, and then consistently looking for previous notes during future appointments. While these workarounds might be effective to various degrees, they were generally regarded as failure-prone, particularly when a patient follows up with a provider other than the one initially seen.

3.5.4.4 Subsection Summary

VistA/CPRS are integral to the delivery of timely and accessible care to Veterans. Previous studies have identified a number of strengths and weaknesses of the current technology; our findings confirm them and highlight ways in which CPRS can impact access to care. Whereas VistA was once considered the vanguard, an aging architecture and 10 years of limited development has threatened its future viability. However, interviews across the spectrum of VA personnel—from management and IT thought-leaders to CPRS end-users—suggest strong support for renewed investment in a modern home-grown product rather than transitioning to a commercial off-the-shelf alternative. Interviewees expressed belief that many of the shortcomings of VistA/CPRS are also shortcomings of commercial systems.

We have not evaluated new IT initiatives such as VistA Evolution that are currently in the development stage. These are covered in Assessment H.

3.5.5 Data Exchange

As stated above, ensuring that providers are able to view all available clinical information is an important component of access to care. Whether the missing data are located inside or outside VA, the detrimental impact on access is similar. All U.S. health care providers face challenges exchanging information, especially with other institutions. We describe four forms of data exchange relevant to VA: between local VA systems, with DoD, with private-sector providers, and directly with patients.

3.5.5.1 Data Exchange Between Local VA Systems

Clinical data within each VAMC are stored in a unified medical record and are easily accessible to any facility within that administrative parent, which is similar to other large provider organizations. Data sharing across administrative parents is currently available through the Remote Data Viewer, a more recent application called VistAWeb, and an application currently being rolled out called Joint Legacy Viewer. All these applications allow providers to view data in other VAMCs, but they do not allow providers to do any other operations such as order tests. Our interviews with key informants suggest that they are used frequently by many VA clinicians every week. Clinicians noted limitations with these applications in terms of their ability to integrate seamlessly as part of their workflows, which likely has resulted in lower use than is clinically optimal, while others were unfamiliar with these capabilities altogether. They mentioned that the interface is quite different from that of CPRS for local data, which might be an impediment to some clinicians. Several key informants agreed that data exchange across VISNs works well if a user knows that the data exist (that is, if the user does not think to look for outside records, their existence will not be apparent). One key informant said, "VistAWeb is a hidden gem that people don't know enough about."

One key informant acknowledged that provider IT capabilities that allowed for better workflow integration would save clinicians time, but suggested that usage of existing data exchange capabilities was widespread enough that improvements would not result in large benefits to patients, as most clinicians can find the data when they really need them. In contrast, another said a better integrated system would allow Veterans access to better quality and more timely medical advice, especially Veterans who travel frequently. The integration of medication data is more robust. When a clinician prescribes a medication, the Veteran's drug history is checked against all medications prescribed in any VA location.

While private-sector organizations also face similar challenges with data exchange, direct comparisons to VA are difficult due to differences between organizations and lack of data. The science of data exchange usage measurement is still in its infancy.

VA plans to replace its existing data exchange functionality as part of its VistA Evolution rollout. This version is designed to integrate data across all administrative parents. The primary barriers to improving internal data exchange are technical and organizational in nature and are covered in Assessment H.

3.5.5.2   Data Exchange with DoD

Interest in sharing data between VA and DoD is long-standing. Approximately 400,000 TRICARE beneficiaries receive VA care in a given year (calculated by the authors from the 2010 National Survey of Veterans [Westat, 2010]). Some VA and DoD facilities share resources, and if these arrangements expand, the need for VA-DoD data exchange will also increase.

VA clinicians currently can access DoD data for many years through VistAWeb using the same workflow as accessing data from other VA regions. Reports from stakeholders indicate this happens roughly 250,000 times per week. However, the DoD record is often a scanned report, which limits its utility, especially if it is dozens or hundreds of pages long. They also mentioned that retrieving DoD records is feasible but that providers often do not bother because it is not worth the effort. One said, "I have never seen information on the DoD system."

For VistA Evolution, VA plans to make interoperability with DoD systems a priority and to achieve this by December 31, 2016 (VA, 2014g). This involves creating a unified lifetime health record for Veterans and service members that can be accessed by clinicians at any point in time, regardless of where the information is stored. One benefit of this upgrade is the facilitation of care coordination between providers from different facilities, which may increase the quality of and access to care. In addition, the integration and intercommunication between medical devices can result in time savings and fewer errors in Veteran care. Assessment H describes VistA Evolution in greater depth.

3.5.5.3   Data Exchange with Private-Sector Providers

The purpose of the Virtual Lifetime Electronic Record (VLER) project is to facilitate data exchange between VA and the private sector. This kind of data exchange among unaffiliated institutions is known as health information exchange. In development for roughly five years, the project is partnering with 35 external organizations. In 2012 there were 1,764 unique VA

providers who retrieved data from a provider outside VA (Byrne et al., 2014). More recent data supplied by key informants found 800 transactions per week in which a VA provider sought and received data from a private-sector provider.

Key informants familiar with the VLER project identified the following barriers to data exchange between VA and external organizations:

- Consent: Federal laws require consents from each patient (Goldstein & Rein, 2010).
- Technology: Finding the records can take as much as four minutes.
- Record matching: Finding patient records is challenging because of variation in which traits the data partners use to identify patients; VLER has found the most success matching records based on Social Security number, but the number is being used less frequently.

These barriers are consistent with the findings from evaluations of other health information exchanges (Rudin et al., 2014). Studies of other exchanges have emphasized workflow barriers, which may also be a problem with VLER, but we did not speak with end-users so we cannot be certain. Because VLER is being developed for use within VistAWeb, workflow barriers may be less of a concern for VA than for other exchanges. Other barriers related to technical issues are discussed in Assessment H.

Some of the above barriers are being addressed by VA. For example, to confront delays, VLER is experimenting with pre-accessing a patient's records prior to a visit. Other barriers, such as the patient record matching problem, are an issue for all health information exchanges.

It is difficult to evaluate the VLER project based on usage data because of the nascent state of health information exchange usage measures and little evidence of value brought by exchanges. Three recent literature reviews found limited evidence of impact other than in the emergency department and usage on the order of two to 10 percent of visits. By connecting with 35 distinct partners with 15 vendors (for VLER DIRECT) and beginning to share data, VA maybe at the forefront of interorganizational, cross-vendor data exchange. However, as noted in a recent systematic review, relatively few data exchange initiatives have been formally evaluated (Rudin et al., 2014).

3.5.5.4 Data Exchange with Veterans Directly

Veteran access to their own medical record can serve two purposes. The first is that, until more robust data exchange methods are in place, Veterans can carry their own medical record on visits to their providers. The second, which is discussed in Subsection 3.5.2, is that access to a personal record may allow Veterans to keep better track of their health encounters and increase their understanding of their medical conditions.

As stated in Subsection 3.5.2, VA is a leader in providing patients with access to their own health data via the "Blue Button" mechanism, which allows them to download their entire record from MyHealtheVet in a standardized electronic format. Considering that around 70 percent of Veterans access health care through non-VA facilities, tools such as "Blue Button" could help improve the quality and coordination of care (Hynes et al., 2007; Nazi et al., 2014).

Barriers to improved access are the same as those of access to MyHealtheVet (see Subsection 3.5.5.2).

3.5.6 Care Management

Care management programs attempt to proactively provide care for patients with the goal of improving outcomes and saving costs that can be spent for other purposes, such as expanding access. IT has the potential to be an important component in care management. Care management is an active area of research and development in VA and other organizations. For this reason, we did not attempt to document the complete inventory of IT capabilities that support care management in VA, which includes a wide range of functionalities such as registries, dashboards, and predictive analytics (Wang et al., 2013a). Few such programs have been formally evaluated and it is difficult to assess the capability without such an evaluation.

One program that has been evaluated in VA is the home telehealth program, which was implemented nationally in 2003 to 2004. Published in 2014, a retrospective matched cohort study of 4,999 Veterans found that the costs of patients receiving home telehealth decreased by 4 percent, while the cohort not receiving home telehealth saw a 48-percent increase (Darkins, 2014). The author contrasts VA's program with others, pointing out that VA's program involves a "biopsychosocial model" in which care coordinators give more than technical advice. A 2013 audit of the home telehealth program by the Office of Inspector General questioned whether this capability was used to its greatest potential, pointing out that its recent growth does not includes the kinds of patients who would most benefit (VA, Office of Inspector General, 2015d).

3.5.7 Overarching Informational Resources Issues

Several themes emerged across the various IT capabilities. These include the existence of organizational barriers, the need for more widely available wireless internet at VA facilities, the tension between information security and accessibility, and the existence of several innovative programs to improve VA's IT capabilities.

3.5.7.1 Organizational Barriers

Managers and providers across the VA system commented on the organization's ability to develop, maintain, and deliver IT tools. On one hand, the dynamic nature of these technologies requires an agile development process that is able to quickly iterate and enhance products. Units involved in this process highlight that administrative barriers in the approval process stymie development and that there is generally "too much focus on planning and reporting and not enough on execution."

On the other hand, there is a lack of strategic focus in how management has addressed technology issues on a project-by-project basis, instead of holistic product management. Hence, different lines receive varying levels of attention and budget. These organizational issues, along with others related to communication across units, have an impact on IT strategy and are addressed in greater detail in Assessment H.

3.5.7.2 IT Infrastructure: Wireless Internet at VA Facilities

Wireless Internet (wifi) enables use of mobile technology, such as iPads, both for patients and for providers. However, according to the results of our facilities survey, wifi is not widely available at VA medical centers. According to survey respondents, patients and guests can expect blanket wifi everywhere at only 21 percent of VAMCS, and no wireless Internet at all in almost 40 percent. Staff have higher rates of reliable access, but 38 percent of them also have no access at VAMCs. Wifi access is even lower at CBOCs, where 72 percent have none for patients and 64 percent do not have it for staff. Even when there is access, it is often not extensive or reliable. The lack of reliable wifi likely impedes innovation in and use of mobile health applications at VA.

3.5.7.3 Security versus Access to Information

As demand for new health IT applications increase, there is a heightened tension between keeping the information secure while at the same time allowing it to be accessible at the appropriate times and places. We found that this tension tends to manifest in the form of how existing security policies are interpreted and implemented.

3.5.7.4 Future Improvements

For all the capabilities we investigated, there were plans for improvements. We focused primarily on VA's existing rather than projected capabilities, because it is challenging to accurately project IT capability into the future. In particular, it is difficult to know which IT projects will succeed, as many fail or are delayed, in VA and in the IT industry in general. It is beyond the scope of this work to exhaustively describe VA's innovation program and would be impossible to accurately predict which ones will have the most potential for scaling and the extent to which they will improve timely and accessible care for Veterans. Instead, we briefly mention a few innovative projects under way as illustrative examples.

- Mobile CPRS: This capability will allow providers to access the medical record on their mobile device.

- Proxy access into MyHealtheVet: This capability will allow family or friends of Veterans to more easily serve as caregivers by allowing them to log in to the Veteran's medical record, with permission from the Veteran.

- Annie texting program: The Annie program—named after Lt. Annie G. Fox, the first woman to receive the Purple Heart for combat—is in a pilot stage. It focuses on texting patients with congestive heart failure, diabetes, hypertension, and weight concerns as well as sending appointment reminders. The scope will expand after the pilot is evaluated (Evans, 2014).

- Watson: VA has a new $16 million contract with IBM Watson, which has been discussed in the media (for example, Ravindranath, 2014) though VA has made little information available to date. One VA interviewee described a plan to use Watson to "find lurking problems in the medical record"; the tool can review medical notes to identify missed problems, and then the clinician can check to see what data contribute to identifying that problem. It also is capable of searching the medical literature. The VA employee posited that, "this could save 3–5 minutes per visit based on better searching for information in the record."

3.5.8 Subsection Summary

Overall, we found that VA is extensively using many health IT capabilities in a variety of ways that support delivery of timely and accessible care to Veterans. Our assessment shows that VA is on par or exceeds other organizations' capability to use IT in care delivery in many regards.

For example, telehealth—the use of technologies to provide clinical care when distance separates patients and providers—has been a focus for VA for more than a decade, and VA is now recognized as a world leader in this area. Users of MyHealtheVet express satisfaction with the site's content, functionality, and performance. VA also continues to develop mobile applications (apps)—software that Veterans can download and use from their smartphones to monitor their health.

Among every capability, we found clear barriers to further taking advantage of what IT can offer. Some of these barriers are faced by all health systems, while others are unique to VA. Although telehealth has grown rapidly, its growth has fallen short of VA targets, reaching 11–12 percent of Veterans in 2013 and 2014; key barriers to further use include insufficient space for telehealth, inadequate infrastructure and support, and lack of leadership/provider buy-in. There are also barriers to expanding use of MyHealtheVet, including the administrative burden on users of registering and issues with the technology. Providers also face barriers that decrease their willingness to use the system, including a lack of integration with other clinical data systems. VA mobile apps hold great promise to increase access to care, but due to limited functionality and requirements surrounding their use, there is little evidence that they have done so to date.

Previous studies have identified a number of strengths and weaknesses of the current VistA/CPRS technology; our findings confirm them and highlight ways in which CPRS can impact access to care. Whereas VistA was once considered the vanguard, an aging architecture and 10 years of limited development has threatened its future viability. However, interviews across the

spectrum of VA personnel—from management and IT thought-leaders to CPRS end-users—suggest strong support for renewed investment in a modern home-grown product rather than transitioning to a commercial off-the-shelf alternative. Interviewees expressed belief that many of the shortcomings of VistA/CPRS are also shortcomings of commercial systems.

3.6   Section Conclusion

VA operates a unique health care system with broad and deep resources and capabilities. However, VA faces many barriers to using resources in the most effective way that will need to be addressed in order to improve performance for Veterans. Some of these barriers are specific to VA, while some affect the U.S. health care system more broadly:

- **Fiscal resources:** We identified concerns about the data used for VA's budget planning as well as challenges related to budgeting inflexibility resulting from the congressional appropriation processes and challenges related to VA's allocation processes.

- **Workforce and human resources:** VA faces shortages of physicians in some geographic areas and of certain physician specialists more generally. These constraints are influenced by a number of factors, including relatively low salaries, a slow credentialing process, and infrastructure constraints. There are also challenges associated with VA workforce planning and assessment processes, including challenges in selecting methods, identifying external benchmarks, and obtaining complete and accurate data.

- **Physical infrastructure**: Interviewees in leadership or clinical care positions were generally satisfied with VA medical equipment and supplies, but they noted that physical space was in short supply and that it was difficult to update the physical space in older buildings to accommodate new medical technology and equipment.

- **Purchased care:** VA has many outside options for purchasing care, including several programs and various types of payment or contractual arrangements. However, managing these overlapping programs has been a challenge.

- **IT resources:** VA has been and continues to be an innovator and leader in developing IT capabilities, although there is room for improvement in some areas, including issues related to the management and planning of its IT systems. Among every IT capability we studied, we found clear barriers to further taking advantage of what IT can offer, including inadequate infrastructure, lack of facility leadership and provider buy-in, and administrative burden.

In the next section, we examine how VA's resources and capabilities are utilized by assessing Veterans' access to VA care.

4 Assessment of Access to VA Care

As discussed in the previous section, VA operates a unique health care system with broad and deep resources and capabilities. However, ensuring Veterans' access to health care depends not just on the level of resources and capabilities available, but on how well VA's health care system addresses Veterans' needs. In this section, we assess Veterans' access to care along the five dimensions described in Section 1: geographic, timely, financial, digital, and cultural. For each dimension, we describe access within the VA system, compare access in VA to non-VA settings when reasonable comparisons are available, describe consequences of access deficiencies, and outline potential opportunities for improvement.

These analyses use many data sources, including Veteran and enrollee locations and demographics, inventories of VA and non-VA medical facilities and infrastructure, U.S. road network data (to estimate distances), performance measures tracked by VA, evidence from peer-reviewed literature, qualitative interviews with VA health care administrators (VISN quality management and medical officers, VAMC associate directors, CBOC directors and site managers) and health care providers (CBOC and VAMC providers, VAMC nurses and paraprofessionals), and online reviews of VA facilities.

A summary of methods used in these analyses is shown in the box.

Overview of Methods and Data for Access to VA Care

- We conducted a systematic literature review to examine the accessibility of VA care across the five dimensions of access (geographic, timely, financial, digital, cultural) and to identify facilitators and barriers of access.
- We analyzed narrative reviews of VA facilities submitted by users of the online rating website Yelp.
- We conducted additional data analyses specific to each of the dimensions, as described below.

Geographic

- To assess geographic access, we built a GIS, using Esri's ArcGIS Version 10.2. We analyzed enrollee access to VA medical facilities with different levels of complexity and different capabilities using several different access standards, including a 40-mile straight line distance, 40-mile driving distance, 60-minute driving time, and 60-minute public transit time. In all analyses, we assessed variation in geographic access estimates by VISN.
- We also estimated geographic access to purchased care for enrollees living outside the 40-mile driving distance boundaries around VA medical facilities. We assessed access to non-VA facilities with different levels of complexity and different services as well as non-VA clinicians practicing in 12 clinical specialties.
- Data used in these analyses included the VA Survey of Enrollees, Veterans Affairs Site Tracking System, American Community Survey, Esri v10.2 Business Analyst Extension, VA Planning Systems Support Group Enrollee file, VA Clinical Inventory Facility Profile Report, VA Clinical Inventory Facility Services Report,

---

and the SK&A Office-Based Physician, Nurse Practitioner, and Physician Assistant Database.

Timeliness

- We analyzed system-level measures of timeliness, including wait times for primary care, mental health care, and specialty care appointments, as well as Veteran reports regarding access to timely care, appointments, and information from the SHEP PCMH survey. For each measure, we conducted descriptive analyses of the performance rates available at the facility level, noting the variation in performance across facilities nationwide. For measures with rates available for more than one year, we created a descriptive time series and classified changes over time as improving, worsening, or remaining the same.
- We also analyzed five years of data (2010–2014) from the Survey of Enrollees to describe attitudes of Veterans related to timely access to VA care. Data used in these analyses included VSSC, VA SHEP PCMH Survey, and VA Survey of Enrollees.

Financial

- To assess financial access, we assessed the cost of VA care, out-of-pocket expenses, and Veterans' perspectives regarding the value of VA care. For these analyses, we used data from the Medical Expenditure Panel Survey and VA Survey of Enrollees.

Digital and Cultural

- Our assessment of digital and cultural access focused, respectively, on Veterans' internet access and Veterans' perspectives regarding the degree to which VA personnel treat them with respect. In measuring digital and cultural access, we used data from the VA Survey of Enrollees.

- For complete details of the methods used to assess access in all of these dimensions, please refer to Section 2 of this report and Appendix A-1.

4.1   Geographic Access

In this report, we have defined geographic access as the ease of traveling to health care providers. For example, how far does a Veteran live from needed health care services? How long does it take to travel to appointments? Is it possible for the Veteran to take public transportation, and if so, how long is spent in transit? As described above, geographic access is one of several types of access. Because the Veterans Choice Act set a standard of 40 miles maximum distance from VA medical facilities, geographic access is an important dimension for our assessment of VA health care.

4.1.1 Effects of Geographic Factors on Enrollment in VA, Use of VA Health Care Services, and Health Outcomes

Travel time to VA facilities and availability of transportation affect enrollment in VA, reliance on VA, and use of certain health care services. Although Veterans may face similar challenges in traveling to care regardless of whether the care is provided by VA or private-sector providers (Wakefield et al., 2007), VA health care providers we interviewed noted that a long distance from a facility or concerns about transportation to the nearest facility may lead Veterans to seek alternative sources of health care. Studies of female, Medicare-eligible, and rural Veterans support this view, finding that these Veterans are less likely to seek or continue to seek care from VA if they live farther away from VA facilities (Petersen et al., 2010; Buzza et al., 2011; Liu et al., 2011; Hamilton et al., 2013; Nayar et al., 2013; Friedman et al., 2015). Similarly, Veterans who are eligible for both VA care and Medicare are more likely to rely on Medicare than VA if they live in rural areas or metro-adjacent areas, or live more than 50 miles from a VA facility (Hynes et al., 2007; Kramer et al., 2011; Shen et al., 2005; Weeks et al., 2005). Veterans who live farther from VA facilities have been shown to be less likely to visit a VA pharmacy for prescriptions, receive a transplant, have radiation treatment, or use radiology or laboratory services at a VA facility than Veterans who live inside VA service areas or in urban areas (Weeks & West, 2007; French et al., 2012; Patterson et al., 2014).

In interviews, VA health care workers concurred with findings of prior studies reporting that although coordination and continuity of care within VA are generally good, challenges are faced by those who live far away (McCarthy et al., 2007; Skolarus et al., 2013). One study of Veterans with serious mental illness found that those who lived farther from VA had fewer visit days, but more visits per day, suggesting that Veterans who live farther away are more likely to "chain" appointments by scheduling more than one in a single day (McCarthy et al., 2006).

Veterans who live farther from health care facilities also face a greater likelihood of adverse health outcomes. For example, greater distance from a VA or other transplant center has been shown to be associated with lower likelihood of being waitlisted for a liver transplant and receiving a liver transplant, and greater likelihood of death among Veterans who are eligible for liver transplantation (Goldberg et al., 2014). Another study found that distance from a VA facility was significantly associated with PTSD symptom presentation. In particular, female Iraq and Afghanistan Veterans living 11 to 25 miles from the closest VA facility were twice as likely as Veterans located 0 to 10 miles from the nearest facility to belong to intermediate and high-symptom PTSD latent classes (Hebenstreit, Madden, & Maguen, 2014).[42]

Although distance and transportation are the dominant factors determining Veterans' geographic access to VA care, availability of convenient parking may also affect Veterans' use of VA facilities. Insufficient parking was among the top 10 most common themes described in the

---

[42] The authors suggest that further research is needed to examine whether Veterans with higher-intensity PTSD live in rural regions because their acuity demands it, or whether distance from treatment elevates disease acuity.

online rating website Yelp reviews about VA facilities; of 1,547 comments posted to Yelp about VA facilities between 2007 and 2015, 6 percent mentioned parking, with twice as many comments noting inadequate parking than adequate parking.

4.1.2 Alternative Standards for Geographic Access to Care

The Veterans Choice Act defines geographic access to care using a standard of a maximum distance of 40 miles between a Veteran's residence and any VA medical facility. Veterans living within 40 miles of a medical facility are considered to have adequate geographic access to care. Those living beyond this distance are eligible for the Veterans Choice Program, which provides Veterans with an opportunity to seek purchased care located closer to their homes. This standard was initially measured by VA along a straight line between residence and facility, but was reinterpreted in March 2015 as driving distance measured along roadways (Hicks, 2015).

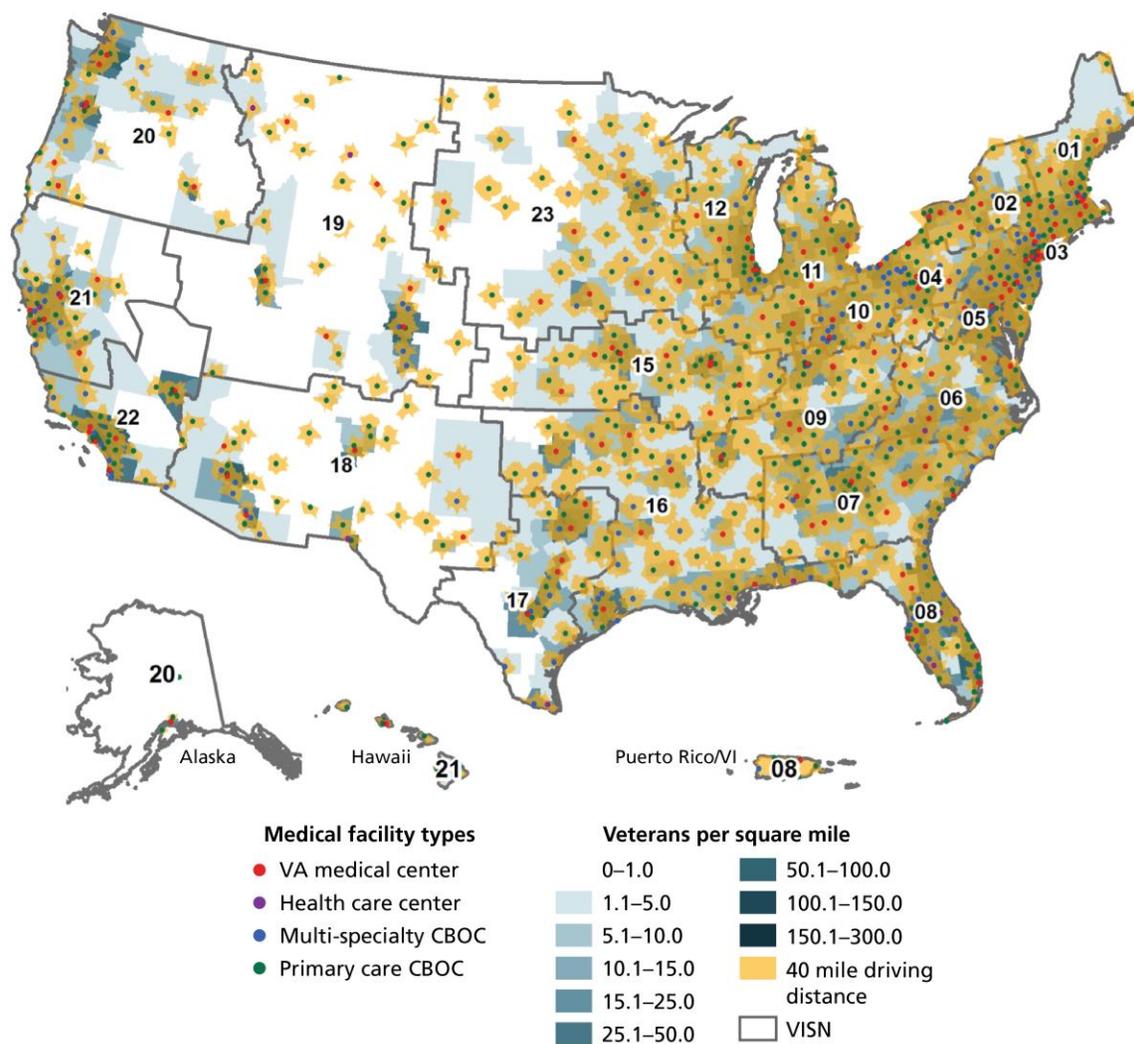
The recent change in this rule illustrates that the standard for geographic access can make a difference in who qualifies for the Veterans Choice Program. In this subsection, we examine alternative standards for geographic access to care, including 40-mile straight-line and driving distances, among others.

4.1.2.1 The 40-mile Driving Distance Standard

Figure 4-1 shows the geographic distribution of VA medical facilities (VAMCs, health care centers, multispecialty CBOCs, and primary care CBOCs) surrounded by 40-mile driving distances for enrollees.[43] VA medical facilities of different types are shown as colored dots. Concentrations of enrollees are shown in blue-gray areas, with darker shades representing places where more enrollees live. The 40-mile areas around VA medical facilities are depicted with yellow-shaded polygons. Figure 4-1 shows that 40-mile driving distances surrounding VA facilities reach the vast majority (92.7 percent) of VA enrollees.

---

[43] Figure 4-1 shows enrollees' geographic access to VA medical facilities, while Figure 3.3-1 showed VA medical facilities and population density of all Veterans (including enrollees and non-enrollees).

Figure 4-1. Enrollees' Geographic Access to VA Medical Facilities: 40-Mile Driving Distance


Medical facility types
- 🔴 VA medical center
- 🟣 Health care center
- 🔵 Multi-specialty CBOC
- 🟢 Primary care CBOC

Veterans per square mile

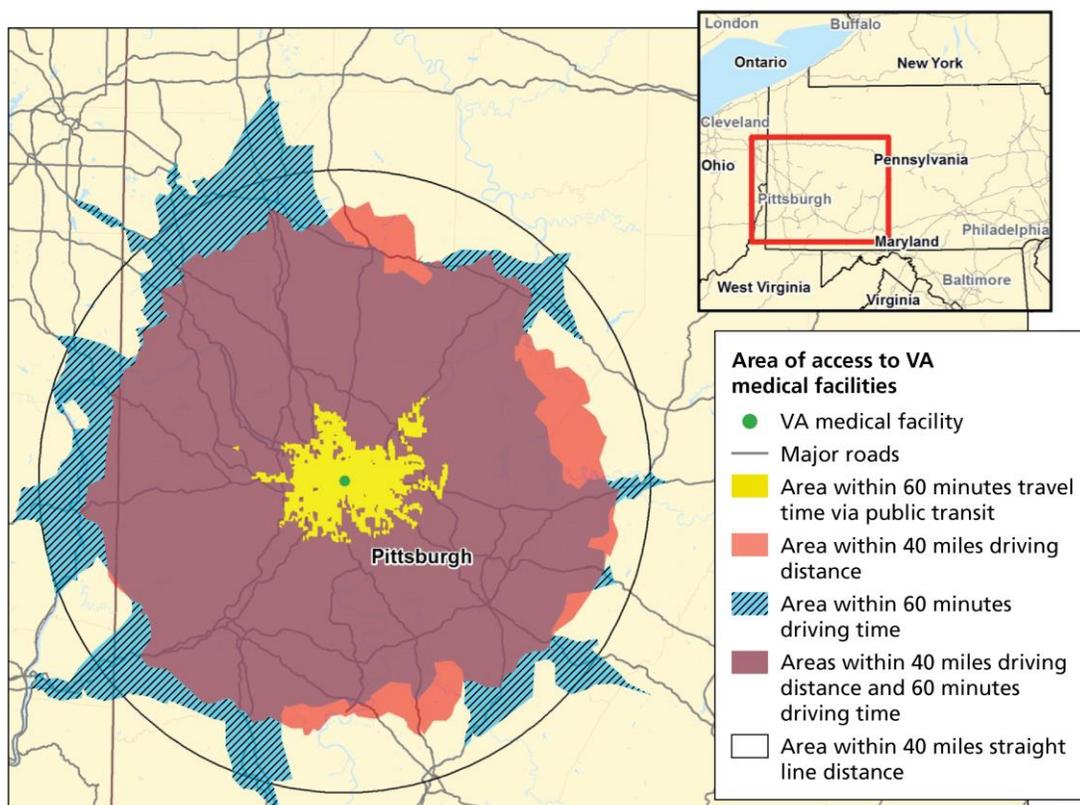
0–1.0	50.1–100.0
1.1–5.0	100.1–150.0
5.1–10.0	150.1–300.0
10.1–15.0	40 mile driving distance
15.1–25.0	VISN
25.1–50.0	

Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.

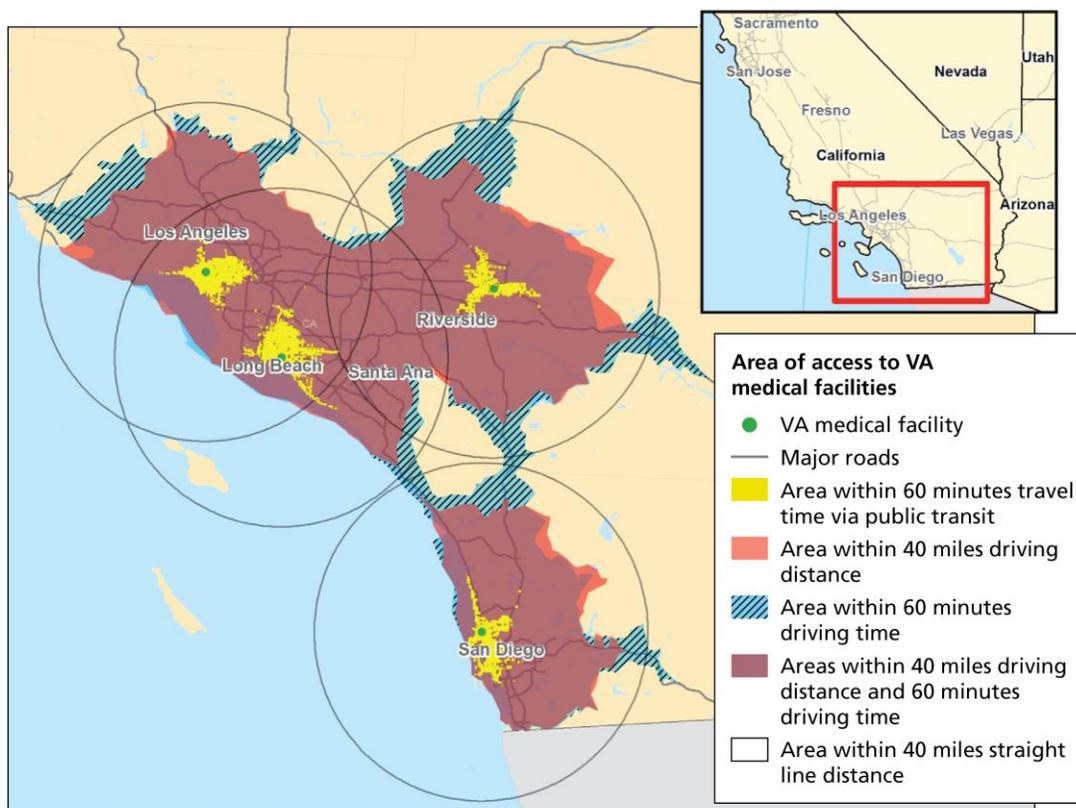
4.1.2.2   Other Geographic Access Standards

A limitation of this distance standard is that it does not account for differences in travel speed in urban versus rural areas or in private versus public transportation. Enrollees traveling in rural areas and by private vehicle may cover 40 miles much more quickly than those in urban areas or by public transportation. An alternative approach accounts for travel *time* instead of *distance*, a standard used widely in studies of geographic access to care (Branas et al., 2005; Klein et al., 2009; Concannon et al., 2010; Concannon et al., 2011; Concannon et al., 2013; Barbash et al., 2014). Travel time can further be considered for people with access to a car and for people using public transportation. Figures 4-2 and 4-3 show how four standards of geographic access overlap in Pittsburgh, Pennsylvania, and Southern California, respectively.

The 40-mile straight-line distance standard is depicted as a gray circle around the VA medical facility. The 40-mile driving distance standard is shown in red. The 60-minute driving time is shown in blue; areas of overlap between this standard and the 40-mile driving distance standard are shown in purple. The 60-minute public transportation time standard is shown in yellow.

Figure 4-2. Four Geographic Access Standards in Pittsburgh


Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.

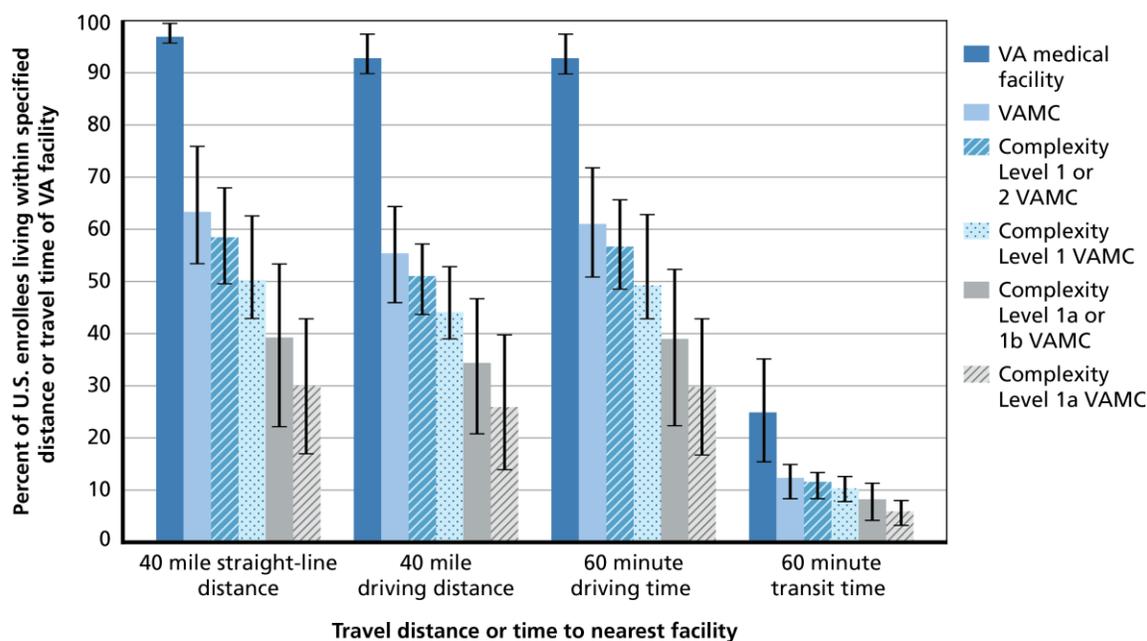
Figure 4-3. Four Geographic Access Standards in Southern California


Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.

These maps show that 40-mile and 60-minute driving areas are comparable in Pittsburgh, while the 60-minute driving time area—without accounting for traffic slowdowns—covers more ground in Southern California. The 60-minute public transportation areas are much smaller, illustrating challenges associated with accessing VA services without a car.

4.1.3   Enrollees' Geographic Access to VA Care

Figure 4-4 shows how the four standards of geographic access would affect the estimated proportion of enrollees who have geographic access to different levels of complexity at VA medical facilities. The standards for geographic access—40-mile straight-line distance, 40-mile driving distance, 60-minute driving time (in free-flow traffic), and 60-minute public transit time—are arrayed in four groups along the x-axis. Within each group, geographic access to VA medical facilities is presented in six bars representing access to facilities with different levels of complexity.

Figure 4-4. Geographic Access to VA Facilities, by Type of Facility and Standard


Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.
Notes: Vertical bars represent national estimates. Black lines on the bars represent the interquartile range of values across 21 VISNs.

4.1.3.1   Enrollees' Geographic Access to Any VA Medical Facility

Overall, the first three standards do not differ a great deal in their summary effects on estimates of geographic access to any VA medical facility (Figure 4-4). The left-most bar in each group presents the proportion of enrollees that have geographic access to any VA medical facility (N = 871). The 40-mile straight-line distance standard results in an estimate of 96.8 percent of enrollees (N = 8,367,877) having access while the 40-mile driving distance results in an estimate of 92.7 percent and a 60-minute driving time standard results in an estimate of 92.8 percent.

By changing the standard from straight line to driving distance, therefore, we estimate that VA more than doubled the number of enrollees meeting geographic access criteria for eligibility for the Veterans Choice Program, from 3.2 percent (N = 289,516) to 7.3 percent (N = 658,890) of enrollees.

If enrollees rely on public transportation, they face a significant barrier to access. Only 24.9 percent of all enrollees live within a 60-minute transit time from any VA medical facility (Figure 4-4). There is substantial variation across VISNs in the percentage of Veterans within 60-minute transit time to a VAMC or CBOC (interquartile range, 15.3 percent to 35.2 percent; range, 9.3 percent to 60.1 percent). The Veterans Transportation Service does not currently collect information on the number of enrollees who use public transportation to get to and from

medical care. This may be useful information to collect in future planning for supplemental transportation services.

4.1.3.2   Enrollees' Geographic Access to Higher-Complexity VA Medical Facilities

Geographic access to higher-complexity VA medical facilities is considerably lower than the estimates of access to any facility. The five right-most bars in each grouping in Figure 4-4 show how geographic access estimates fall with each increasing level of medical facility complexity. For geographic access to care provided at VAMCs, the percentage of enrollees residing less than 40 miles driving distance away drops from 92.7 to 55.3 percent of enrollees. Fewer enrollees have access to higher-complexity facilities: 50.9 percent live within 40 miles of complexity level 1 or 2 facilities, 44.0 percent have access to complexity level 1 facilities, 34.3 percent have access to complexity level 1a or 1b facilities, and 26.0 percent have access to complexity level 1a facilities.

Our estimates of average driving distances to VA medical facilities with different levels of complexity also show that geographic access is more difficult as complexity levels increase (Table 4-1). The average driving distance to any VA medical facility is 15.4 miles for all enrollees (standard deviation = 15.7 miles). This distance increases to 41.4 miles (standard deviation = 39.0 miles) when driving to a VAMC, 44.8 miles (standard deviation = 42.7 miles) to a level 1 or 2 VAMC, 52.9 miles (standard deviation = 50.7 miles) to a level 1 VAMC, and 80.9 miles (standard deviation = 65.1 miles) to a level 1a VAMC.

Table 4-1. Mean (Standard Deviation) Driving Distance to Closest VA Medical Facility (in miles), by Type of Facility

Type of VA Medical Facility	All Enrollees	Enrollees Residing >40 Miles from Nearest VA Medical Facility	Enrollees Residing <40 Miles from Nearest VA Medical Facility
Any VA Medical Facility (N = 871)	15.4 (15.7)	57.9 (21.2)	12.2 (9.3)
Any VAMC (N = 163)	41.4 (39.0)	91.7 (38.6)	16.5 (10.5)
Complexity Level 1 or 2 VAMC (N = 129)	44.8 (42.7)	97.6 (42.2)	16.6 (10.6)
Complexity Level 1 VAMC (N = 97)	52.9 (50.7)	109.3 (46.9)	16.6 (10.5)

Type of VA Medical Facility	All Enrollees	Enrollees Residing >40 Miles from Nearest VA Medical Facility	Enrollees Residing <40 Miles from Nearest VA Medical Facility
Complexity Level 1a or 1b VAMC (N = 64)	66.0 (60.5)	122.2 (50.8)	17.0 (10.4)
Complexity Level 1a VAMC (N = 47)	80.9 (65.1)	128.1 (50.7)	17.4 (10.5)

Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.

Notes: Facility counts changed over the study period as a result of site reclassifications. The numbers in this report come from an April 2015 extract from Veterans Affairs Site Tracking System that followed a major VA site reclassification in March of 2015.

4.1.3.3   Enrollees' Geographic Access During Rush Hour Traffic

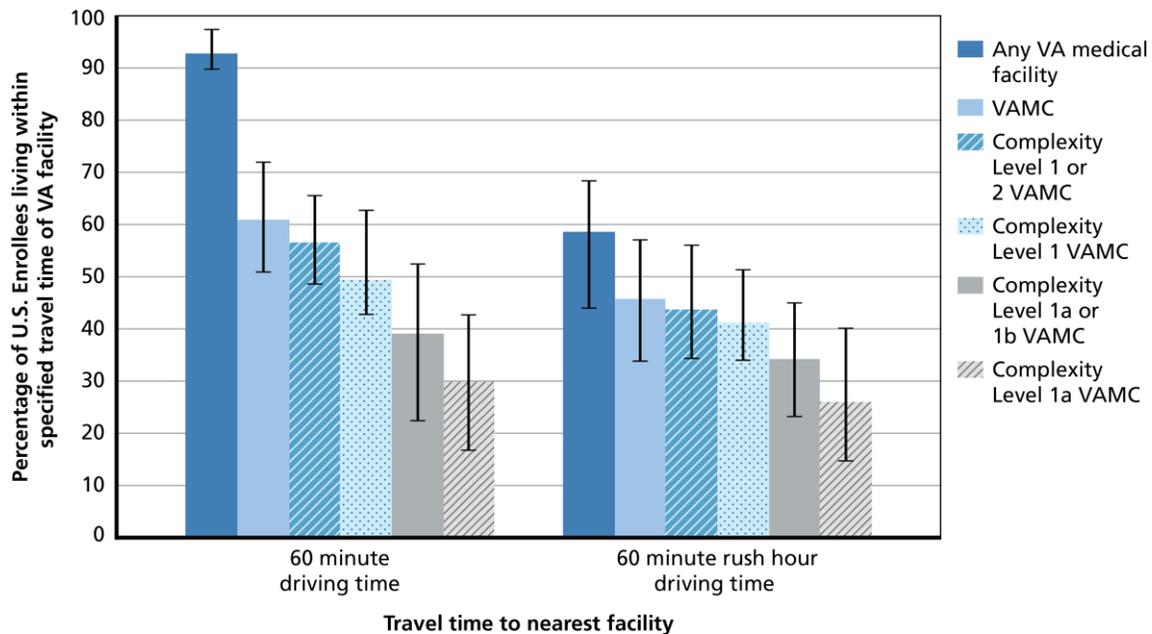
Driving time standards account for geographic features like road networks, elevation, geographic barriers, and area differences in travel speeds. A limitation of these standards, however, is that they typically do not account for traffic slowdowns. We use the 2012 Urban Mobility Report[44] (Schrank, Eisele, & Lomax, 2012) to adjust for slowdowns during typical peak rush hour (6 to 10 AM and 3 to 7 PM) travel. For example, a travel time index of 1.30 indicates a 20-minute trip at free-flow speeds takes 26 minutes (30 percent longer) during rush hour periods.

Figure 4-5 compares driving times to VA medical facilities in normal free-flow traffic and rush hour traffic in the 101 metropolitan areas with travel time index values available. The percentage of enrollees within 60 minutes driving time of any medical facility drops from 93.9 percent in free-flow travel to 82.3 percent in peak traffic.[45] Similarly, the percentage of enrollees with 60-minute driving time access to facilities with different complexity levels declines by four to eight percentage points in rush hour traffic compared with free-flow traffic.

---

[44] We obtained the travel time index for 101 metropolitan areas. Travel time indices for other metropolitan regions were not available

[45] Because this analysis was conducted in the subset of 101 metropolitan regions in which the travel time index values were available, this estimate is slightly different than the 60-minute driving time estimate across the United States.

Figure 4-5. Geographic Access to VA Facilities During Rush Hour Traffic, by Standard


MS4675B-4.5

Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.

Notes: Vertical bars represent national estimates. Black lines on the bars represent the interquartile range of values across 21 VISNs.

4.1.3.4   Enrollees' Geographic Access to Specific Types of VA Care

The Veterans Choice Program eligibility standards are measures of access to any medical facility; they do not account for whether needed services are available at that facility. We measured geographic access to 27 services (Table 2-7) that may be needed in the care of one or more of seven illustrative clinical populations. We mapped variables from VA's clinical inventory profile and services to these 27 services; the mapping and variables are shown in Appendix Table F-10. To examine how geographic access estimates change when one of these services is needed, we estimated the percentage of enrollees at the VISN and national levels with access to each one of these services (Table 4-2). Estimates of geographic access among Veterans and enrollees using both the 40-mile driving distance and 60-minute driving time standards are presented for all 27 services in Appendix F.

Table 4-2. Enrollees' Geographic Access to VA Clinical Population-Specific Services

Services (by Clinical Population)	Percentage of Enrollees Living within 40 Mile Driving Distance of a VA Facility with the Service	Enrollees' Mean (Standard Deviation) Driving Distance to the Nearest VA Facility with the Service (in miles)
Acute Coronary Syndromes		
Non-invasive cardiology services	58.3	39.3 (37.7)
Emergency department	50.2	45.9 (42.3)
Coronary care unit	50.1	46.0 (42.4)
Interventional cardiology	43.4	53.4 (48.7)
Telemetry (if CCU/ICU is not available)	35.2	63.5 (55.7)
Diagnostic cardiac catheterization	42.0	54.2 (49.9)
Cardiac surgery	39.7	58.3 (51.2)
Colon Cancer		
Primary care clinic	91.8	15.8 (16.1)
Computerized tomography scan	60.0	38.3 (36.6)
Oncology services	55.3	42.1 (41.1)
Colonoscopy	58.0	40.0 (38.8)
Surgical services	54.3	42.4 (39.8)
TBI		
Specialty care	62.0	36.6 (36.8)
Polytrauma support clinic team	36.9	59.7 (50.0)
Polytrauma network site	20.8	86.8 (66.8)
Polytrauma Rehabilitation Center (Program)	4.4	118.2 (70.3)
Type II Diabetes Mellitus		
Primary care clinic	91.8	15.8 (16.1)
Diabetes specialty or endocrinology clinic	72.2	29.8 (32.7)
Podiatry clinic	70.3	30.7 (33.2)
Ophthalmology clinic	53.8	43.9 (41.0)
PTSD		
Mental health services	90.4	16.4 (17.3)

Services (by Clinical Population)	Percentage of Enrollees Living within 40 Mile Driving Distance of a VA Facility with the Service	Enrollees' Mean (Standard Deviation) Driving Distance to the Nearest VA Facility with the Service (in miles)
Psychotherapy	84.7	20.3 (22.2)
Domiciliary Residential Rehabilitative Treatment Program	17.5	88.0 (57.7)
SUD		
Mental health services	90.4	16.4 (17.3)
Outpatient specialty care	81.8	22.5 (23.5)
Methadone	68.9	32.5 (35.3)
Inpatient detoxification	52.4	44.2 (40.7)
Residential treatment	29.2	73.9 (58.7)
Conditions Requiring Gynecological Surgery		
Gynecological surgery services	48.4	46.8 (43.9)

Sources: Authors' analysis of Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.
Note: The percentage of enrollees with access to telemetry is based on only those facilities without CCU/ICU services.

Almost 92 percent of all enrollees have geographic access to primary care services, critical for screening and diagnosis of populations needing advanced specialty care. However, substantially lower proportions of enrollees have geographic access to advanced and specialized services in VA facilities. Between 35 percent and 58 percent of enrollees have access to specialized services for acute coronary syndromes (Table 4-2). Similar figures for other specialized services are between 54 and 60 percent for specialized colon cancer care, and between 54 and 72 percent for specialized diabetes care.

Though some conditions are found much more commonly in Veterans than in other populations, geographic access to care for these conditions is often at or below 50 percent. Residential services for PTSD and SUD are accessible to 18 percent and 29 percent of enrollees, respectively (Table 4-2). Patients with active SUD have 52.4 percent access to inpatient detoxification services. Only 4.4 percent of enrollees have geographic access to a polytrauma rehabilitation center for TBI under this standard, while 20.8 and 36.9 percent have geographic access to a VA polytrauma network site and a VA polytrauma clinic team, respectively. While the nature of residential services means that the actual distance from home is less important than for outpatient or short inpatient care, it also means that Veterans living at more distant facilities may be far away from family or other support networks.

Specialized services for women's health are a growing need for VA; 48.4 percent of enrollees have geographic access to this type of care.

4.1.3.5   Variation Among VISNs in Enrollees' Geographic Access

The estimates in Figures 4-4 and 4-5 are national estimates of geographic access to VA medical facilities. These estimates vary across VISNs. The black bars in both figures represent the interquartile range[46] of geographic access estimates across VISNs. The percentage of Veterans meeting the 40-mile driving distance and 60-minute driving time standards does not vary widely across VISNs from the 25th to 75th percentile of the distribution.

However, some VISNs are outliers in terms of geographic access. Analysis of geographic access in VISNs below the 25th percentile and above the 75th percentile shows that outlier VISNs have substantially different levels of geographic access. For the five VISNs ranked below the 25th percentile, geographic access using the 40-mile driving standard is between 5 and 26 absolute percentage points below the national average. For the five VISNs ranked above the 75th percentile, estimates are between 5 and 42 absolute percentage points above the national average (data not shown). Those with the lowest rates of geographic access are more likely to be located in rural areas, particularly the Midwest and Northwest regions (data not shown). Those with the highest rates of geographic access are more likely to be located in urban areas, particularly the Mid-Atlantic and Northeast regions.

4.1.3.6   Benchmarks for Geographic Access Standards

Setting a geographic access standard is a *de facto* normative judgment about how far or how long Veterans should be willing or able to travel for medical care. The Veterans Choice Act defines geographic access as care that is available within a 40-mile driving distance of a Veteran's residence. In this subsection, we compare this standard with benchmarks outside and inside the VA system.

We examined two benchmarks for comparison with VA geographic access standards (Figure 4-6). First, we examined actual driving times between home and the hospital for fee-for-service Medicare beneficiaries using inpatient hospital care.[47] Fee-for-service Medicare is an open provider network, with almost all U.S. non-VA health care providers participating in Medicare and accepting Medicare patients. Therefore, the distance traveled to hospitals by Medicare

---

[46] The interquartile range is estimated by ordering VISN-level estimates from lowest to highest and reporting estimates at the 25th and 75th percentiles. Because there are 21 VISNs, the interquartile range presents a summary of the 11 VISNs that are inclusive of positions 6 and 16 in this ordering. The five VISNs with the lowest estimates of access fall below the interquartile range and the five VISNs with the highest estimates of access rise above the range.

[47] To compute observed travel distances in the Medicare population, we estimated driving times from all Medicare hospital addresses to the centroids of ZIP codes where beneficiaries were discharged from inpatient care. We then computed an average of driving times for all discharged beneficiaries in a ZIP code and estimated weighted-average driving times for all beneficiaries in a VISN. Weights were constructed as the number of cases in the ZIP code over all cases in the VISN.

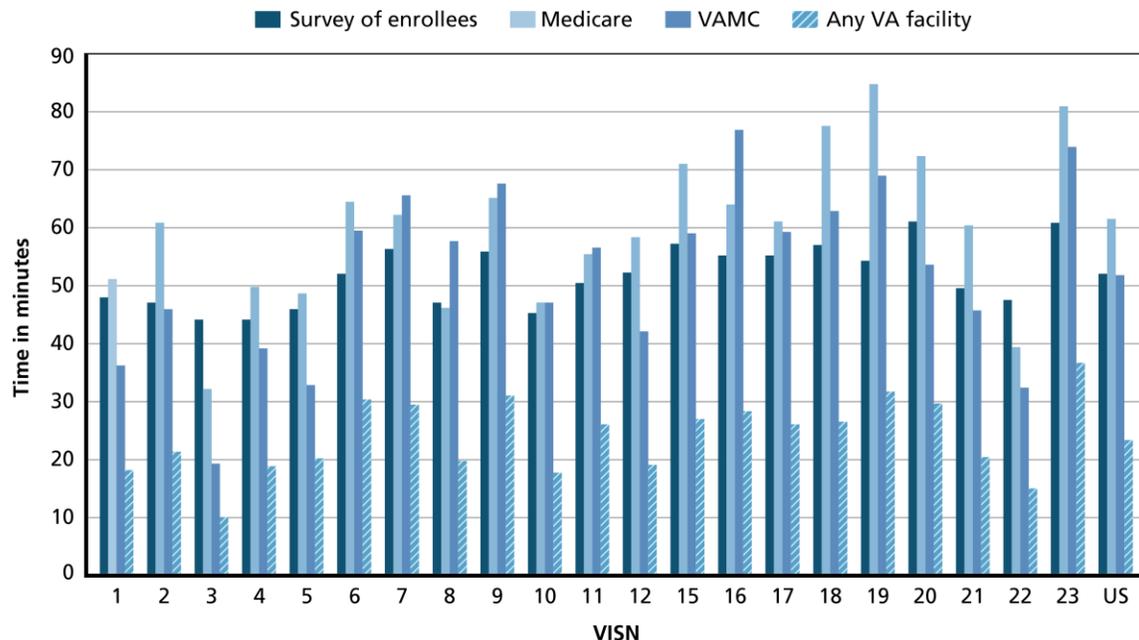
---

beneficiaries reflects the distance that people travel for care in the absence of provider network constraints. Second, we examined stated willingness to travel among Veterans responding to the 2013 Survey of Enrollees. Both benchmarks are measured in terms of time, not distance.

Observed travel times for Medicare beneficiaries varied significantly across VISNs, signaling that a uniform standard across the U.S. may not reflect local practices and expectations. The average estimated travel time across the U.S. among Medicare fee-for-service beneficiaries was 61 minutes. Estimates ranged from an average of 32 minutes in the VISN with the shortest observed times to 85 minutes in the VISN with the longest observed times (Figure 4-6).

Results from the 2013 Survey of Enrollees show an average willingness to travel of just over 50 minutes for medical care. This is lower than the 60-minute alternative standard. The data also show narrower variation from place to place, from a low of 44 minutes in one VISN to a high of 61 minutes in another (Figure 4-6).

In comparison, VA enrollees live an average of 52 minutes driving time from the nearest VAMC and 23 minutes driving time from the nearest VA medical facility of any type (Figure 4-6). On average and in most VISNs, these driving times are less than enrollees' reported willingness to travel and Medicare beneficiaries' average observed travel times.

Figure 4-6. Driving Time to Hospitals for Medicare Beneficiaries and VA Enrollee Willingness to Travel


Sources: Authors' analysis of Medicare Hospital Service Area File (2015); VA Survey of Enrollees (2013); and Veterans Affairs Site Tracking System and VA Planning Systems Support Group Enrollee file from second quarter 2015.
Notes: "US" refers to a national estimate for all VISNs. We used travel time from Medicare data

---

to have a direct comparison with the measure of willingness to travel in the Survey of Enrollees. We cut off Medicare estimates of travel above 240 minutes by road networks, assuming that longer travel distances were likely to be made by air. City hubs associated with each VISN are listed in Table 3.1-3.

Our analyses of data from VA's Survey of Enrollees suggest that ease of traveling to care at VA facilities and availability of a VA provider in Veterans' areas may be declining over time. In 2010, almost 80 percent of Veterans responding to the survey agreed it was easy to get to their local VA facility; by 2014, 75 percent of Veterans responding to the survey reported the same. Similarly, the proportion of Veterans who agreed that there was a VA provider in their area that offered the health care services that they need declined from 72 percent in 2010 to 66 percent in 2014. A similar decrease over the same period was reported in the proportion of Veterans who reported that it was easy for Veterans like them to get around in a VA facility.

Significant decreases in the Survey of Enrollees' agreement responses over time have occurred each year from 2010 to 2014. Multivariate models controlling for time trends indicate that decreases are partly attributable to the increasing proportion of Veterans who are younger and female, as these Veterans are less likely to agree that it is easy to get to their local VA facility and that there is a VA provider in their area that offers the services they need. Veteran reports that geographic access to VA care is worsening may also reflect migration of Veterans to regions, such as the south, where VA services are less available, and actual increases in distance to VA facilities due to reorganization and closures.

Our analyses suggest that a uniform driving distance standard may inadequately reflect the needs and expectations of Veterans in different regions of the country. Because this may be the case, a single driving distance standard may prove to be overly restrictive in some areas while placing no real restrictions on eligibility for the Veterans Choice Program in others. In contrast, driving time standards can take into account the usual variation in travel speeds by urban versus rural areas, by private versus public transit, and by free-flow versus peak travel periods. Driving time standards have the added benefit of being adjustable for community-specific experiences and expectations about how long an enrollee should be in transit to and from medical appointments.

Further, adjustments in the standard for populations requiring access to specific types of care seem critical. Enrollees needing access to more complex medical facilities and to specialized services may need to travel farther than 40 miles to gain access. The most extreme example of this is for enrollees seeking rehabilitation services for TBI. Only 4.4 percent of all enrollees live within 40 miles of VA's five polytrauma rehabilitation centers. It would make little sense for VA to expand this program to every VA medical facility; Veterans needing this care are more than likely to seek it from VA and travel great distances to get it. Less extreme examples also illustrate this case. For instance, Veterans seeking access to interventional cardiology may be willing to travel greater distances for this service and VA might consider whether longer distances for this service would be reasonable.

4.1.4 Geographic Access to Non-VA Facilities

4.1.4.1 Characteristics of Enrollees Living More Than 40 Miles from a VA Medical Facility

As shown in Subsection 4.1.3, 7.3 percent (N = 658,890) of enrollees live more than 40 miles driving distance from any VA medical facility. In terms of age, gender, priority group, and prevalence of selected conditions, these populations are quite similar to their counterparts who live closer to VA medical facilities (Tables 4-3 and 4-4).[48]

Table 4-3. Demographic and Service Characteristics of Enrollees Living Inside and Outside 40-mile Driving Distances from VA Medical Facilities

	No. (%) Living <40 Miles from a VA Facility (N = 8,367,877)	No. (%) Living >40 Miles from a VA Facility (N = 658,890)
Age and Gender		
Age under 35	858,625 (10)	48,364 (7)
Age 35–44	771,827 (9)	42,931 (7)
Age 45–54	1,094,119 (13)	64,431 (10)
Age 55–64	1,567,668 (19)	122,199 (19)
Age 65 and older	4,079,453 (49)	381,195 (58)
Female	629,593 (8)	33,602 (5)
Service Characteristics		
Priority group 1	1,743,412 (21)	136,748 (21)
Priority group 2	673,452 (8)	48,827 (7)
Priority group 3	1,133,392 (14)	87,508 (13)
Priority group 4	226,290 (3)	16,038 (2)
Priority group 5	1,894,864 (23)	160,762 (24)
Priority group 6	547,878 (7)	43,214 (7)
Priority group 7	402,507 (5)	17,525 (3)
Priority group 8	1,749,963 (21)	148,498 (23)
Service-Connected Disability	3,790,366 (45)	290,003 (44)

---

[48] Because this comparison is drawn from complete data on a large population and not from sampling data, significance testing is non-informative and over-powered, and therefore, was not performed.

Any purchased care utilization	1,031,335 (12)	113,249 (17)

Source: Authors' analysis of Planning Systems Support Group Enrollee File.
Note: Total enrollees = 9,026,767.

Table 4-4. Clinical Characteristics of Enrollees Living Inside and Outside 40-mile Driving Distances from VA Medical Facilities

Clinical Conditions	No. (%) <40 Miles from a VA Facility	No. (%) >40 Miles from a VA Facility
Acute coronary syndromes, emergency care	24,253 (0.3)	2,300 (0.4)
Colon cancer, primary care	27,657 (0.3)	2,515 (0.4)
TBI, specialty care	96,044 (1.1)	6,265 (1.0)
Diabetes, primary care	1,012,664 (12.1)	88,925 (13.5)
PTSD, mental health services	532,363 (6.4)	41,409 (6.3)
Substance abuse, outpatient specialty care for SUD	347,987 (4.2)	19,996 (3.0)
Women's health, gynecological surgery services	22,289 (0.3)	1,140 (0.2)

Sources: Authors' analysis of Planning Systems Support Group Enrollee File and VA Encounter data.
Notes: Information on conditions was only available on Enrollees who are users of health care. Number of VA patients = 5,799,131.

Younger and female enrollees are more likely to live within 40 miles from a VA medical facility, while older enrollees are more likely to live beyond 40 miles (Table 4-3). The distribution of enrollees by priority group was similar for enrollees living less than compared with more than 40 miles from a VA medical facility. A higher proportion of enrollees living more than 40 miles from a VA medical facility used purchased care (17 percent compared with 12 percent of enrollees living less than 40 miles from a VA medical facility).

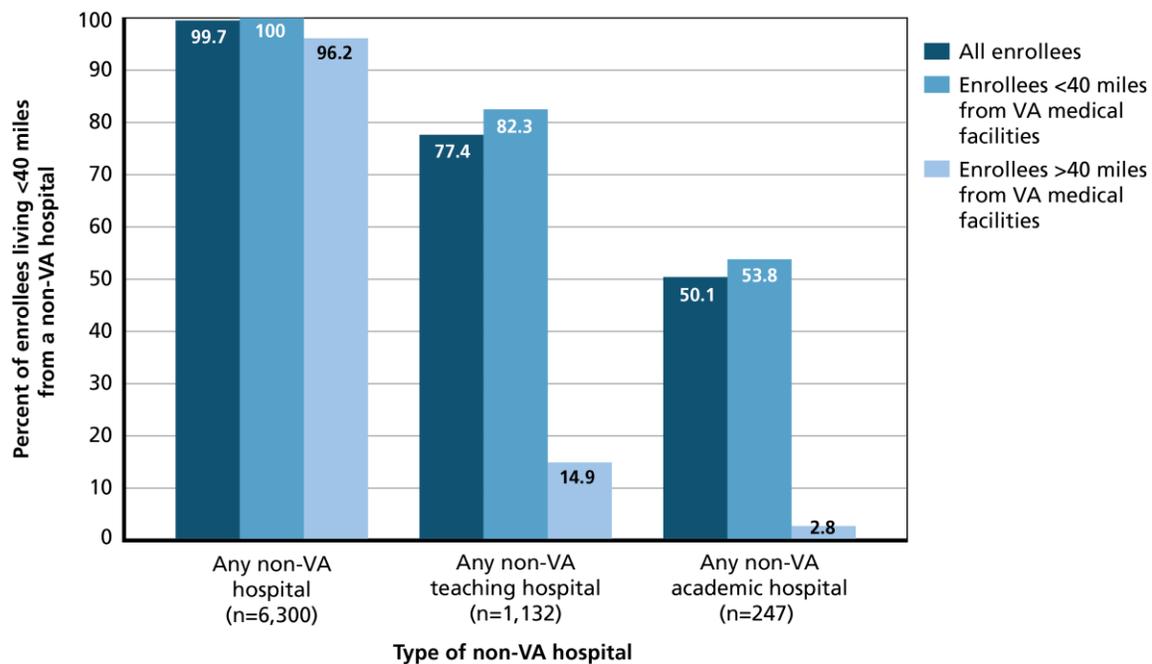
Comparing the percentage of enrollees diagnosed with the clinical conditions, the difference between enrollees living less than 40 miles versus more than 40 miles from a VA medical facility is less than 0.5 percent, except for diabetes, in which a slightly greater proportion of enrollees lives more than 40 miles away (13.5 percent versus 12.1 percent), and substance abuse, in which a slightly lower proportion lives more than 40 miles away (3 percent versus 4.2 percent) (Table 4-4).

4.1.4.2 Enrollees' Geographic Access to Non-VA Hospitals

Many Veterans have other health insurance coverage and use non-VA health care facilities as well as VA health care facilities. The Veterans Choice Program aims to increase access to non-VA facilities for Veterans without geographic or timely access to VA facilities. Figure 4-7 shows

the percentage of Veterans with access to three types of non-VA hospitals: (1) any hospital, (2) teaching hospitals (those with residency programs), and (3) academic hospitals (a subset of teaching hospitals that have a medical school affiliation). Teaching and academic hospitals are shown because they typically have advanced capabilities similar to higher-complexity VA medical facilities.

Most enrollees who live more than 40 miles from VA facilities live within 40 miles of a non-VA hospital (96.2 percent). However, access to non-VA academic and teaching hospitals is much more limited for enrollees who do not have geographic access to VA care (Figure 4-7). Of enrollees living more than 40 miles from VA facilities, 14.9 percent live within 40 miles of a non-VA teaching hospital and 2.8 percent live within 40 miles of a non-VA academic hospital.

Figure 4-7. Geographic Access to Non-VA Hospitals, for All Enrollees, Enrollees <40 Miles from VA Medical Facilities, and Enrollees Residing >40 Miles from VA Medical Facilities


Sources: Authors' analysis of Veterans Affairs Site Tracking System from second quarter 2015 and American Hospital Association Annual Survey of Hospitals; VA Planning Systems Support Group Enrollee file.
Note: Geographic access is defined in this figure as <40 miles driving distance between home and the hospital.

Enrollees living more than 40 miles from VA facilities face an average driving distance of 12.5 miles (standard deviation = 13.0 miles) to the nearest non-VA hospital (Table 4-5). Driving distances to more advanced hospitals are much higher for this population. Enrollees more than 40 miles from VA medical facilities drive 66.4 miles (standard deviation = 34.2 miles), on average, to the nearest teaching hospital and 97.2 miles (standard deviation = 46.5 miles) to the nearest academic hospital.

Table 4-5. Average Driving Distance for Enrollees to Closest Non-VA Hospitals by Hospital Type (in miles; standard deviation shown in parentheses)

Non-VA Hospital Type	All Enrollees	Enrollees Residing >40 Miles from Nearest VA Medical Facility	Enrollees Residing <40 Miles from Nearest VA Medical Facility
All (N = 6,300)	5.8 (6.3)	12.5 (13.0)	5.3 (5.1)
Teaching (N = 1,132)	21.6 (27.5)	66.4 (34.2)	10.8 (10)
Academic (N = 247)	43.5 (46.5)	97.2 (46.5)	14.2 (10.4)

A similar pattern can be observed when considering access to highly specialized services that can be delivered only in a hospital.[49] Our estimates of geographic access to seven hospital-only services in non-VA hospitals shows that this type of care is widely accessible to enrollees overall (Table 4-6), from a low of 84.1 percent (coronary care unit) to a high of 99.1 percent (emergency departments).

The great majority of VA medical encounters are not time-sensitive on a scale of minutes to hours. Acute coronary syndromes is one possible exception. For some patients with heart attack, delays as short as 15 minutes may have prognostic significance. Patients with ongoing chest pain are recommended to call 911, and emergency responders typically transport patients to the nearest appropriately resourced hospital. Therefore, the differences in drive times between VA and non-VA hospitals are of interest.

We measured the distribution of enrollee-level drive time differences between VA and non-VA hospitals (See Tables F-43 and F-44, Appendix F). Considering any VA or non-VA hospital, we found that the median additional drive time to a VA hospital was 31.0 minutes (inter-quartile range, 11.4–70.2 minutes). The additional drive time to a VA facility was less than 15 minutes for 31.4 percent of all enrollees, and less than 30 minutes for 49.2 percent.

We repeated the analysis considering only VA and non-VA hospitals with interventional cardiology capability. In this case, median additional drive time was 34.2 minutes (inter-quartile

[49] These include seven services for two of the illustrative clinical populations we have been considering throughout this report. These services differ from the other 20 services insofar that they can only be delivered in a hospital setting. While VA has complete inventories of all 27 services in all of its facilities, there is no single, comparable data resource in the private sector.

range 10.9–85.7 minutes). The additional drive time to a VA facility with interventional capability (versus any non-VA hospital with the same) was less than 15 minutes for 31.2 percent of Veterans, and less than 30 minutes for 46.9 percent.

Table 4-6. Geographic Access (within 40 Miles) to Selected Non-VA Hospital Services, Enrollees Residing >40 Miles from VA Medical Facilities Compared with All Enrollees

Services (by Clinical Population)	Enrollees Residing <40 Miles Driving Distance of VA Hospital Services (%)	Enrollees Residing <40 Miles Driving Distance of Non-VA Hospital Services (%)	Mean (Standard Deviation) Driving Distance to the Nearest Non-VA Facility with the Service (in miles)

Sources: Authors' analysis of VA Site Tracking System and American Hospital Association Annual Survey of Hospitals; VA Planning Systems Support Group Enrollee file.

Enrollees living more than 40 miles from VA facilities are much less likely to have geographic access to specialized services in non-VA hospitals (Table 4-6). These enrollees are much less likely to live within 40 miles driving distance of coronary care units (26.3 percent), diagnostic cardiac catheterization (40.2 percent), cardiac surgery (20.7 percent), and oncology services (59.1 percent). Non-VA emergency departments provide the one exception: 92.2 percent of enrollees living more than 40 miles from a VA medical facility have geographic access to emergency care at non-VA hospitals.

Our assessment of access to care in non-VA hospitals indicate that nearly all VA enrollees living far from VA medical facilities can drive to community and emergency care within 40 miles, but they are much less likely to have access to academic and teaching hospital care, the sites in

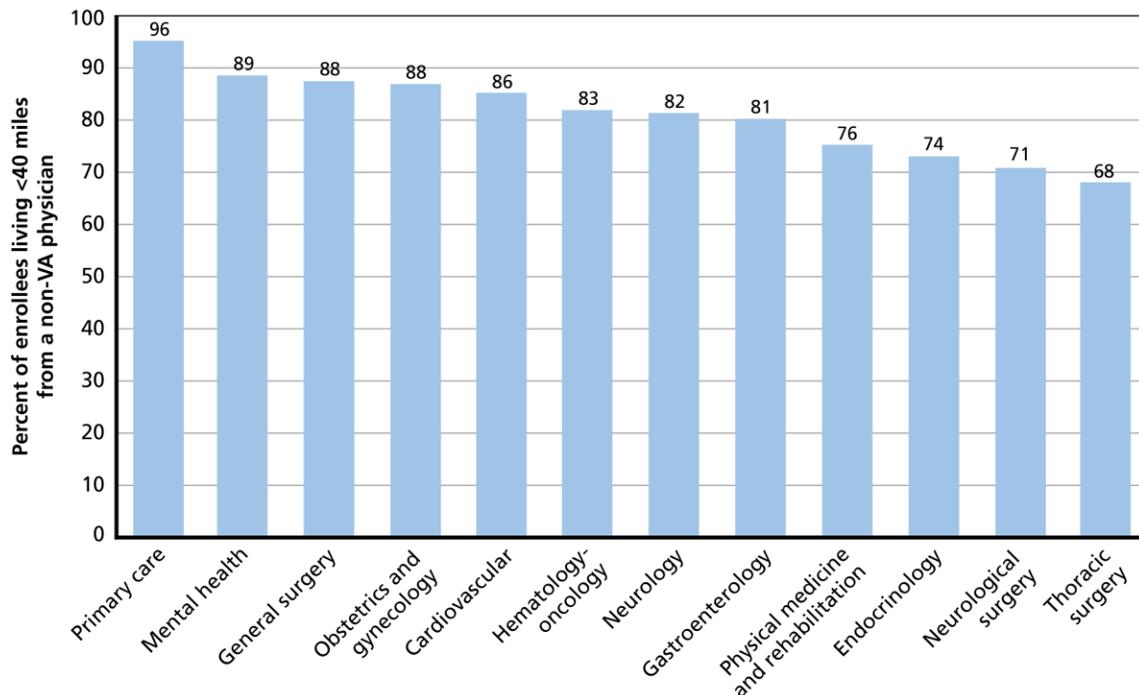
which more complex care is offered. They are also much less likely to have geographic access to a range of highly specialized hospital care, including a range of cardiology, surgery, and oncology services. This finding suggests that expanding access to non-VA hospitals for Veterans living more than 40 miles from a VA facility can help most enrollees seeking routine and emergency care. But far fewer of these same enrollees live within a 40-mile driving distance of complex and specialized hospital care.

4.1.4.3   Enrollees' Geographic Access to Non-VA Providers

In this subsection, we present analyses of VA enrollees' access to non-VA providers in their communities.[50] Many VA enrollees live within 40 miles driving distance of non-VA physicians across multiple specialties. Depending on the specialty, between 68 percent (thoracic surgery) and 96 percent (primary care) of VA enrollees live within 40 miles of a non-VA physician (Figure 4-8). We have no information on wait times at these non-VA providers, but we expect that these wait times are similar to those in the general population. VA enrollees likely face similar levels of geographic access to providers as the general population.

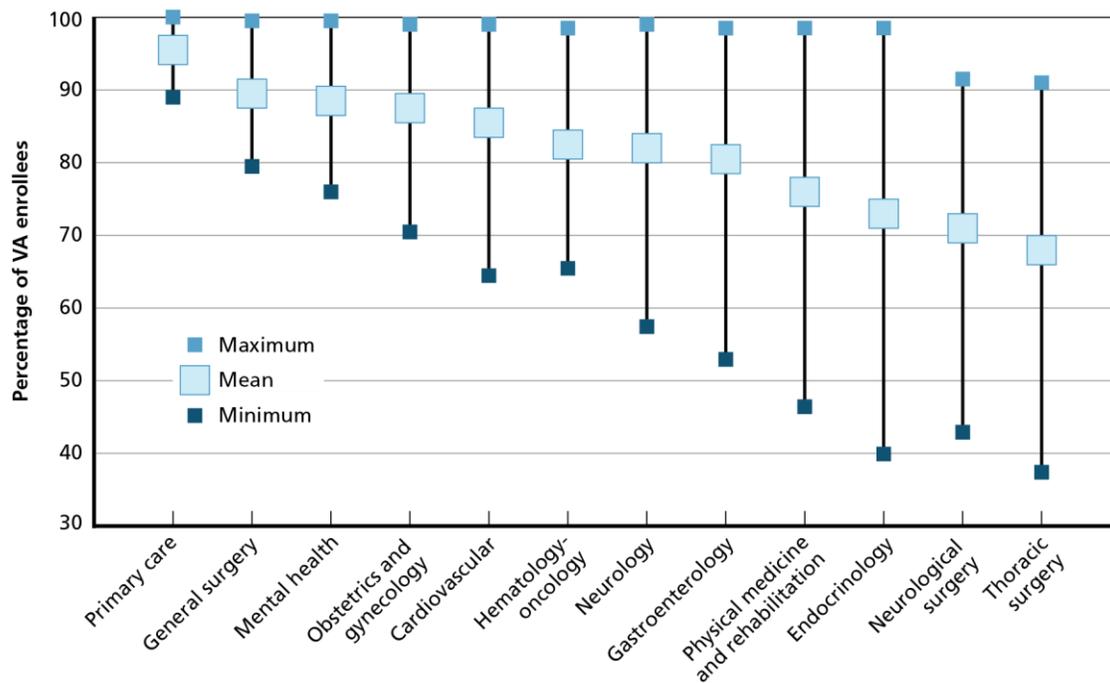
---

[50] These analyses are based on analyses of the SK&A office-based physician database. SK&A has a team of more than 100 researchers who contact all physician offices in the United States every six months to update their database of characteristics of these practices (for example, number of physicians, physician specialty, whether they accept new patients, accept Medicare, accept Medicaid) in order to sell the most updated and accurate information to vendors and pharmaceutical companies.

Figure 4-8. Geographic Access to Non-VA Physicians Among VA Enrollees, by Specialty, 2013


Source: Authors' analysis of SK&A Office-Based Physician Database and VA Planning Systems Support Group Enrollee file.

Geographic access to non-VA physicians varies widely by VISN (Figure 4-9). The smallest variation across VISNs was for primary care physicians, ranging from 89 percent to 100 percent of enrollees living within 40 miles of a primary care physician across the VISNs. We found wide variation, however, across VISNs for a number of specialties. For example, the proportion of enrollees living within 40 miles of an endocrinologist ranges from 40 percent to 99 percent across VISNs.

Figure 4-9. Variation Across VISNs in Geographic Access to Non-VA Physicians Among VA Enrollees, by Specialty, 2013


Source: Authors' analysis of SK&A Office-Based Physician Database and VA Planning Systems Support Group Enrollee file.

We also assessed the average number of non-VA physicians to which each enrollee would have access and the number of those physicians who accept Medicare and new patients. We focused on those that accept Medicare because, under new purchased care initiatives, VA is likely to reimburse physicians at or around Medicare reimbursement rates, because roughly half of VA patients are also covered by Medicare, and because providers who accept Medicare are likely to be eligible Choice program providers. On average, VA enrollees have a number of non-VA providers within a 40-mile radius from which to choose (Table 4-7). For example, VA enrollees within 40 miles of a primary care physician are, on average, near to 700 primary care physicians, of which 495 accept Medicare and new patients, whereas they are within 40 miles of approximately 21 thoracic surgeons, of which 19 accept Medicare and new patients. Again, these numbers are similar to those in the general population, given the distribution of Veterans across the country. These estimates do not provide any information about the accessibility of nearby providers; for example, the providers may have large panels and may not be able to provide timely appointments to patients.

Table 4-7. Average Number of Total Physicians and Physicians Accepting Medicare and New Patients Within and Outside of 40 Miles of VA Enrollees with at Least One Provider in Each Category, 2013

Specialty	Within 40 Miles—Avg. No. Physicians	Within 40 Miles—Avg. No. Physicians Accepting Medicare and New Patients	Outside 40 Miles—Avg. No. Physicians	Outside 40 Miles—Avg. No. Physicians Accepting Medicare and New Patients
Primary Care	699.6	494.7	41.1	29.9
Obstetrics and gynecology	145.4	119.5	10.6	9.5
Mental Health	135.5	84	7.7	5.9
Cardiology	126.2	118.8	10.1	9.9
General Surgery	91.1	80.2	6.8	6.5
Gastroenterology	78.9	74.2	7.5	7.2
Hematology-oncology	78.6	71.7	5.8	5.7
Neurology	72.3	64.5	5.6	5.4
Physical and rehabilitation	39.3	33.9	3.9	3.8
Endocrinology	31.8	28.3	3.5	3.4

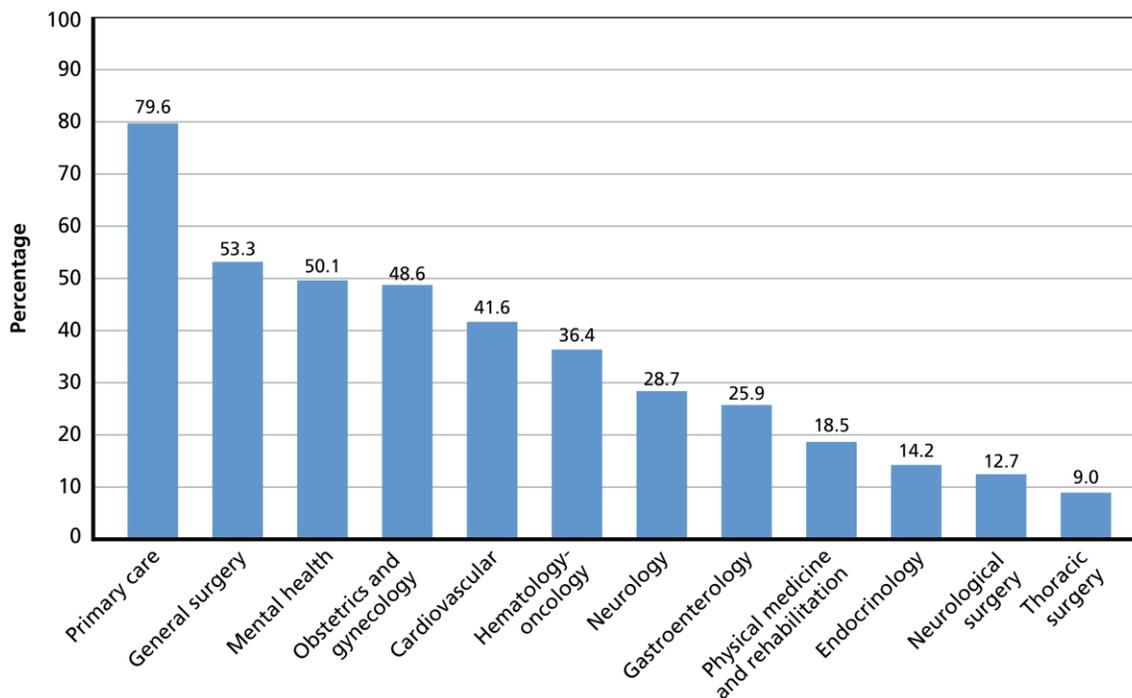
Thoracic surgery	20.9	19.4	3.9	3.8

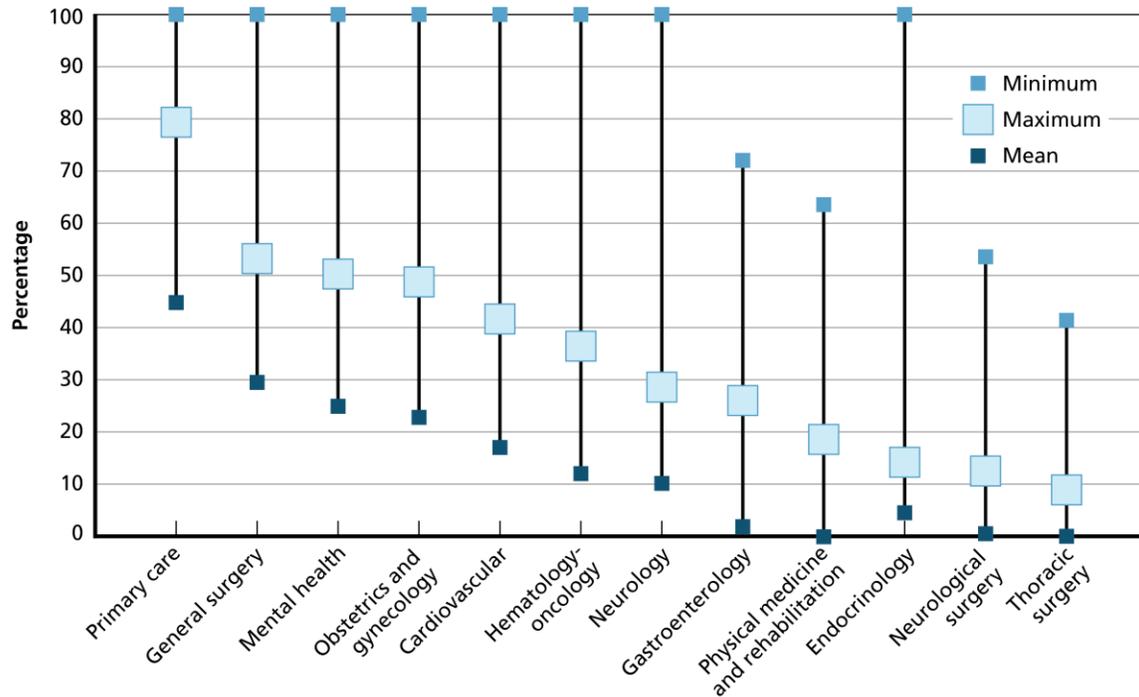
Source: Authors' analysis of SK&A Office-Based Physician Database, VA Site Tracking System, and VA Planning Systems Support Group Enrollee file.

In contrast, we found that enrollees who live more than 40 miles from a VA facility have very poor access to non-VA physicians (Figure 4-10). For all but two specialties, the majority of enrollees who live more than 40 miles from a VA facility live more than 40 miles from any provider in that specialty. Many of the specialties that we examined had extremely low levels of geographic accessibility. For example, only 9 percent of all VA enrollees who live more than 40 miles from a VA facility live within 40 miles of a non-VA thoracic surgeon.

Figure 4-10. Geographic Access to Non-VA Physicians Among Enrollees Residing >40 Miles from VA Medical Facilities, by Specialty, 2013


Source: Authors' analysis of SK&A Office-Based Physician Database, VA Site Tracking System, and VA Planning Systems Support Group Enrollee file.

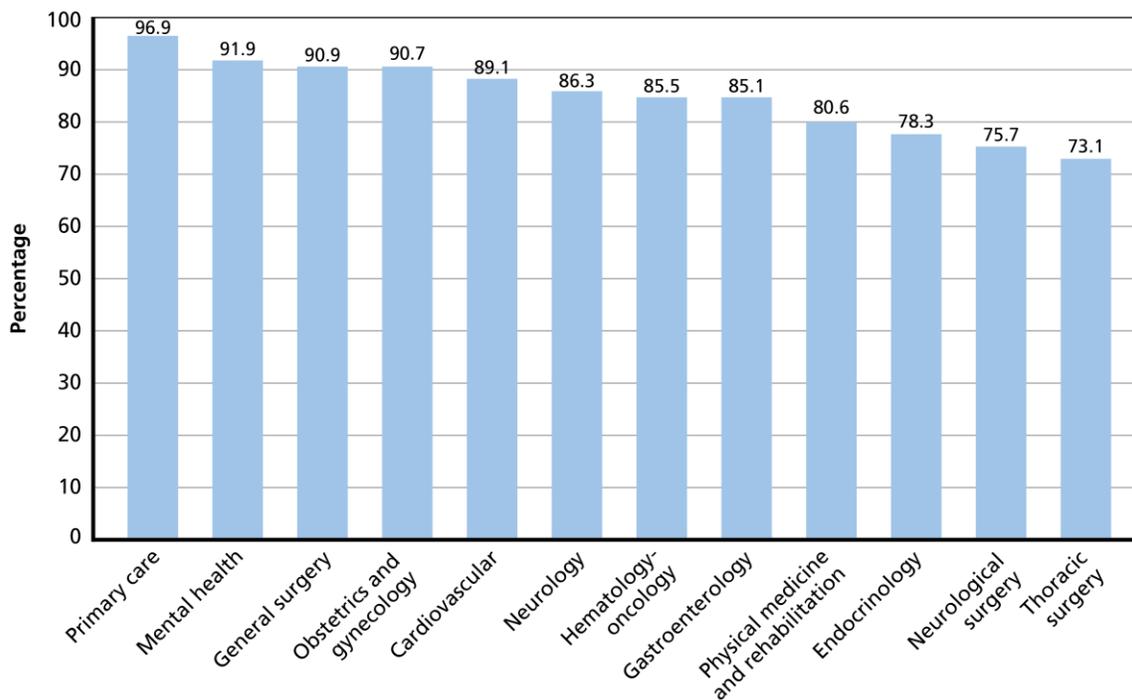
Again, there is significant variation in access to providers across VISNs (Figure 4-11). For example, there is one VISN in which all enrollees more than 40 miles from a facility are also within 40 miles of an endocrinologist, whereas in another VISN only 4 percent of those enrollees are within 40 miles of an endocrinologist. We found similar variation across the majority of the specialties that we investigated.

Figure 4-11. Variation Across VISNs in Geographic Access to Non-VA Physicians Among Enrollees Residing >40 Miles from VA Medical Facilities, by Specialty, 2013


Source: Authors' analysis of SK&A Physician Office-Based Database, VA Site Tracking System, and VA Planning Systems Support Group Enrollee file.

Enrollees who live farther than 40 miles from a VA facility but within 40 miles of at least one non-VA physician in a particular specialty have access to very few physicians within 40 miles of their homes, especially compared with all enrollees (Table 4-7). Enrollees with at least one primary care physician within 40 miles had, on average, 29.9 primary care providers within 40 miles that accepted Medicare and new patients. These enrollees had access to many fewer specialists. For example, enrollees living more than 40 miles from a VA facility had, on average, 3.4 endocrinologists within 40 miles that accepted Medicare and new patients.

Enrollees living within 40 miles of a VA facility have considerably better access to non-VA providers than enrollees living outside of 40 miles (Figure 4-12). The percent of enrollees within 40 miles of a VA facility living within 40 miles of non-VA providers ranges from 96.9 percent for primary care physicians to 73.1 percent for thoracic surgeons.

Figure 4-12. Geographic Access to Non-VA Physicians Among Enrollees Residing <40 Miles from VA Medical Facilities, by Specialty, 2013


Source: Authors' analysis of SK&A Office-Based Physician Database, VA Site Tracking System, and VA Planning Systems Support Group Enrollee file.

There is considerably less variation across VISNs for enrollees living within 40 miles of a VA facility compared with those living outside of 40 miles (Figure 4-13). Generally, the variation increases as the mean access decreases.

Figure 4-13. Variation Across VISNs in Geographic Access to Non-VA Physicians Among Enrollees Residing <40 Miles from VA Medical Facilities, by Specialty, 2013

4.1.5 Subsection Summary

Among enrollees, geographic access to VA care varies when using different types of access standards and by region. For example, enrollees' geographic access to VA care varies according to which access standard is applied (that is, 40-mile straight-line distance, 40-mile driving distance, 60-minute driving time in free-flow traffic, 60-minute public transit time). Enrollees who must rely on public transportation, for example, have much less access than other enrollees.

Geographic access to VA care also varies according to the type of service required. Our assessment found that substantially lower proportions of enrollees have geographic access to advanced and specialized services in VA medical facilities. For example, only about 35 percent to 58 percent of enrollees have geographic access to cardiology services. Access was also low for specialized colon cancer care services (between 55 percent and 60 percent of enrollees) and for specialized diabetes care services (between 54 and 72 percent of enrollees).

While nearly all VA enrollees living far from VA medical facilities live within 40 miles of community and emergency care in non-VA hospitals, they are much less likely to have access to academic, teaching, and highly specialized hospital care. The same is true for access to non-VA clinicians in the community. A large share of VA enrollees living far from a VA medical facility

are within 40 miles of primary care providers but far fewer of these enrollees are near providers offering highly specialized care.

Taken together, these findings suggest that the geographic access standard of 40 miles driving distance may not adequately account for the distances that Veterans would need to travel for more specialized care, whether they are seeking this care at VA or non-VA facilities. Furthermore, because VA beneficiaries that live greater than 40 miles from a VA facility have very little access to non-VA specialists, offering them coverage to non-VA providers may not appreciably improve their access to care especially in the most rural VISNs.

4.2   Timeliness

As noted in Section 1, timeliness is a dimension of access focused on how promptly needed care is available to Veterans (Fortney et al., 2011). The promptness with which needed care is available can be assessed from the perspective of a health care system (for example, wait time to the next available appointment) or from the perspective of patients and families (for example, getting an appointment as soon as needed). Timeliness can be assessed based on the type of care (for example, routine care versus urgent care, primary care or specialty care), or according to the type of patient (for example, people with particular health conditions). Several components of timeliness may be important, such as delays in starting care once a patient is at the facility (for example, time spent in the waiting room or time from arrival to start of treatment) and timeliness in moving through care for a specific problem (for example, time between evaluation, diagnosis, and treatment, between parts of the treatment, or between different services at one visit or across separate visits). Several aspects of timeliness have been shown to present a barrier to care for Veterans, including wait time before obtaining a clinic appointment and wait time in the outpatient waiting room (Villa, Harada, & Huynh-Hohnbaum, 2010; Wakefield et al., 2007).

4.2.1   Measurement of Timeliness of Care in VA

VA measures timeliness with two main sets of metrics. The first, assessed from the perspective of the VA health care system, reflects wait times for appointments for primary care, mental health care, and specialty care. Wait times to obtain an appointment reflect access delays in the health care system (Institute of Medicine, 2015). The second set, assessed from the perspective of Veterans, includes Veterans' responses to a survey regarding their experiences of getting timely appointments, care, and information.

4.2.1.1   Measuring Wait Times for Appointments

No single standard or benchmark for wait times has been established on a national basis for the private sector. Experts have noted the importance of incorporating patient and family perspectives in setting standards for and assessing wait times to ensure that any standard imposed is in keeping with patient and family preferences (Brandenburg et al., 2015). The Institute for Healthcare Improvement recommends that the average number of days between the day that a patient tries to schedule an appointment and the third available appointment for a new patient physical, routine exam, or return visit ("third next available appointment") be the

same day for primary care and two days for specialty care (Institute for Healthcare Improvement, 2015).[51] In the Military Health System, access standards for primary care provided directly to military personnel aim for the third next acute appointment within one day and the third next routine appointment within seven days (Defense Health Agency, 2015).

The National Committee for Quality Assurance 2014 recognition program for PCMH suggests the standard of providing same-day appointments for both routine and urgent primary care (National Committee for Quality Assurance, 2014). Private-sector providers are not bound by standards proposed by authorities on health care quality measurement. In contrast, VA sets targets and reports wait times for primary care, mental health care, and specialty care measured as the proportion of appointments that were completed within a certain number of days of a preferred date.[52] Wait times are calculated separately for new patients and established patients. The preferred date refers to "the date that an appointment is deemed clinically appropriate by a VA health care provider, or, if no such clinical determination has been made, the date a Veteran prefers to be seen" (Federal Register, 2014). This metric takes into account appointments that were moved up, cancelled, rebooked, missed, and/or added during the month. VA considers this to represent most accurately the wait times that Veterans actually experience, as the data reflect when appointments actually occurred rather than the planned timing of pending appointments.

Past investigations identified errors in recording of Veterans' desired appointment dates as well as other practices which may have resulted in VA reporting more favorable wait times than Veterans actually experienced (GAO, 2012c). The history of unreliable information regarding the timing of Veteran appointments has generated ongoing concern regarding the accuracy of VA wait-time data, including the data analyzed for this report.

In our analyses, we place particular emphasis on appointments completed within 30 days of the preferred date because Veterans who need to wait more than 30 days from the preferred date are eligible to seek purchased care through the Veterans Choice Program, and because VA's most current data regarding VA wait times use these metrics. However, we recognize that there are important limitations to using VA data to assess timeliness according to a threshold number of days following a preferred date. First, the reliability of VA wait-time data have not been independently audited across VA facilities for the most recent time period that we report. Therefore, it is possible that some facilities have continued to record inaccurate preferred dates in an effort to report more favorable wait times than Veterans actually experienced at their facilities, or that some facilities have improved the accuracy of reported preferred dates recently in response to public scrutiny. Second, the preferred date metric does not indicate the

---

[51] The Institute for Healthcare Improvement recommends the "third next available" rather than the next available as it is a more accurate reflection of true appointment availability rather than serendipity (for example, available appointments due to cancellations or other unexpected events) (Institute for Healthcare Improvement, 2015).

[52] VA also reports wait times for "other" appointments. The "other" category includes a broad range of different services, including home-based care, laboratory tests, and emergency room care. Wait times averaged across this heterogeneous set of health care services are difficult to interpret. We therefore do not present them in this report.

---

absolute number of days that a Veteran actually waits, but instead measures wait times according to number of days *following* the preferred date, which might be any number of days in the future. VA does not systematically collect and report data on the time intervals *prior* to the preferred date, however. Third, the approach does not distinguish between visits for urgent care (which ideally should occur very shortly after the onset of illness or injury, not 30 days following the clinically indicated date) and visits for routine care (which may be scheduled well in advance). The second two of these limitations are likely a greater problem for assessing wait times for established patients, because for new patients, it is more reasonable to assume that the preferred date is as soon as possible (that is, the next available appointment) for either urgent or routine care.

We asked a range of VA health care administrators and health care workers about VA's measures of access. Respondents repeatedly indicated that it would be preferable to define appropriate wait times for a given condition or population of patients according to clinical indications or evidence, rather than establishing and imposing a blanket 30-day threshold. In addition, some respondents noted that VA facilities' performance on completed appointment measures is a function of many factors, including some factors that may not be in VA's control, such as Veterans not showing up for scheduled appointments. To address this concern, respondents suggested alternative or additional measures that reflect staff efforts to provide access (for example, calls to follow up with Veterans) or availability of appointments. Many further noted the importance of gaining Veterans' perspectives on access to care. The smaller subset of health care workers we interviewed referenced availability of appointments and staffing as challenges to providing timely care; efforts to extend clinic hours and schedule subsequent appointments on the day of the initial appointment were suggested as helpful steps forward.

4.2.1.2   Measuring Veterans' Perspectives on Timeliness of Care

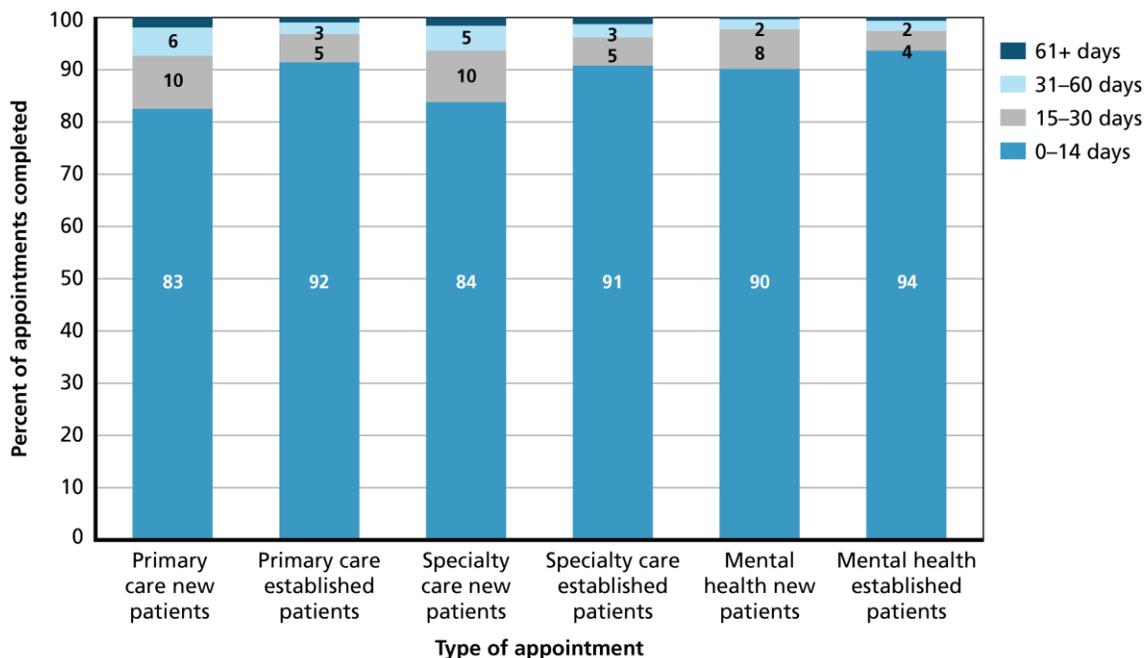
VA collects information on Veterans' experiences of care, including timeliness of care, via the SHEP PCMH (for outpatient care) and inpatient SHEP. Like the CAHPS Clinician and Group Survey and CAHPS Hospital Survey from which they are derived, the SHEP PCMH and inpatient SHEP measure aspects of care that are important to patients, and focus on questions for which the patient is the best or only source of information.

The SHEP PCMH asks Veterans to report on specific experiences of timely access to care, including whether they got urgent care appointments as soon as needed, got routine care appointments as soon as needed, and saw their health care provider within 15 minutes of their appointment time. These measures serve as important complements to measures of VA facility wait times because they assess access to care from the Veteran's perspective. In addition, because the survey questions, data collection procedures, and analyses are implemented in a systematic and standardized manner, SHEP survey results may be used to make fair comparisons between VA facilities, and with some caveats, to compare VA facility performance to CAHPS survey results from non-VA settings.

4.2.2 Average Wait Times for Appointments in VA

In the first half of FY 2015 (October 2014 through March 2015), the most recent period for which wait-time data were available for this report, VA data show that, across facilities, the average number of days that Veterans waited for new patient appointments was approximately six and a half days from the preferred date for primary care, six and a half days from the preferred date for specialty care, and three and a half days from the preferred date for mental health care. The corresponding days waited following preferred date for established patient appointments were four for primary care, four and a half for specialty care, and three for mental health care (data not shown in figure).

During the same time frame, national VA data show that more than 95 percent of VA appointments were completed within 30 days of the preferred date for established patients in primary care and specialty care, and both new and established patients in mental health care (Figure 4-14). Slightly lower percentages (93 and 94 percent) of VA appointments were completed within 30 days of the preferred date for new patients in primary care and specialty care, respectively. The vast majority of these appointments were completed within 14 days of the preferred date.

Figure 4-14. Percentage of VA Appointments Completed Within 0–14, 15–30, 31–60, and 61+ Days of Preferred Date, First Half of FY 2015


Source: Authors' analysis of VA wait-time data for the first half of FY 2015 obtained from the VSSC by The MITRE Corporation.

In the first half of FY 2015, across primary, specialty, and mental health care, VA data indicate that 156,576 new patient appointments (6.2 percent) and 581,562 established patient

appointments (3.5 percent) were not completed within 30 days. If some VA facilities are continuing to tamper with Veterans' preferred dates, the actual number of appointments not completed within 30 days of the preferred date may be even greater. Thus, although VA reports that most appointments meet VA's timeliness standards, some Veterans may still miss needed care or be at risk for poor health outcomes due to long waits for appointments. At VA facilities with average wait times of 30 days or more for the next available primary care appointment, Veterans may be less likely to use health care (Prentice et al., 2012), have less control over chronic conditions such as diabetes (Prentice et al., 2011), and have higher odds of mortality within six months (Pizer & Prentice, 2011) (although worse health outcomes due to longer wait times have not been confirmed by all studies [(Prentice et al., 2012)].

Even when appointments are completed within VA wait-time standards, Veterans may face adverse health outcomes due to delays in care. To assess the clinical meaningfulness of delays, we asked VA facility Chiefs of Staff responding to the 2015 Survey of VA Resources and Capabilities to estimate the proportion of patients who experienced a clinically meaningful delay in care services for each of seven medical conditions. (A list of conditions and rationale for their inclusion is provided in Section 2.) Clinically meaningful delays were defined as those that might put a patient at risk for adverse outcomes, slow resolution of symptoms, or that are not compliant with VA or DoD guidelines. Responses were consistent across conditions: While nearly half of respondents (45 percent) reported that no patients experienced clinically meaningful delays, 42 percent of respondents reported that up to one in four patients experienced a clinically meaningful delay, and an additional 14 percent reported that more than one in four patients experienced a clinically meaningful delay. (More detailed results are described in Appendix B.)

4.2.3 Recent Changes in Wait Times for Appointments in VA

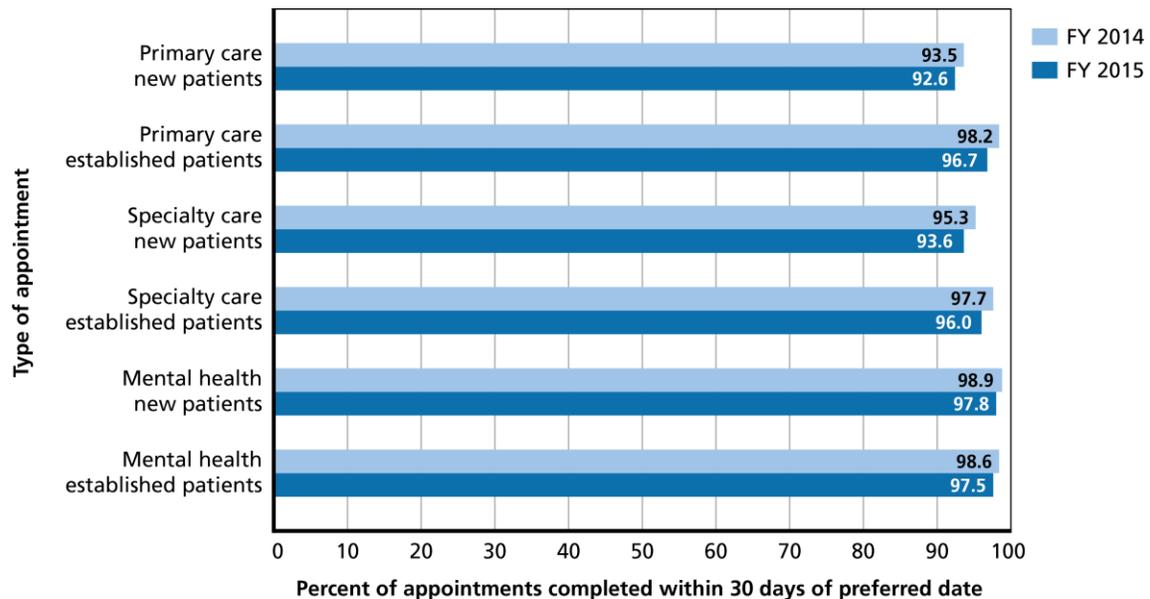
To determine how wait times have changed over time, we assessed changes in the facility-level wait-time measures between the first half of FY 2014 and the first half of FY 2015. To identify meaningful changes over time in a standard way across appointment types, we calculated a standardized effect size using the commonly used Cohen's d formula, and interpreted the size of changes based whether their effect size values met Cohen's thresholds for "small," "medium," or "large" effects. (Details regarding the calculation of trends over time are described in Section 2.)

For all six appointment types, the percentage of appointments completed within 30 days was lower in the first half of FY 2015 than in the first half of FY 2014 (Figure 4-15). Decreases were very small for new patient appointments for primary care, small for new patient appointments for specialty care, medium for established patient appointments for primary care, and large for new and established patient appointments for mental health care and established patient appointments for specialty care. It is unclear whether reported declines in appointments completed within 30 days of preferred date over this period indicate actual lengthening of wait times – as might be expected, given the increased demand for VA services predicted by EHCPM — or reflect improvements in the accuracy of the wait-time data. Since the spring of 2014, hundreds of media stories have described VA wait times. This public scrutiny, in combination with announcements of disciplinary action against employees involved with gaming of reported

The views, opinions, and/or findings contained in this report are those of RAND Corporation and should not be construed as an official government position, policy, or decision.

191

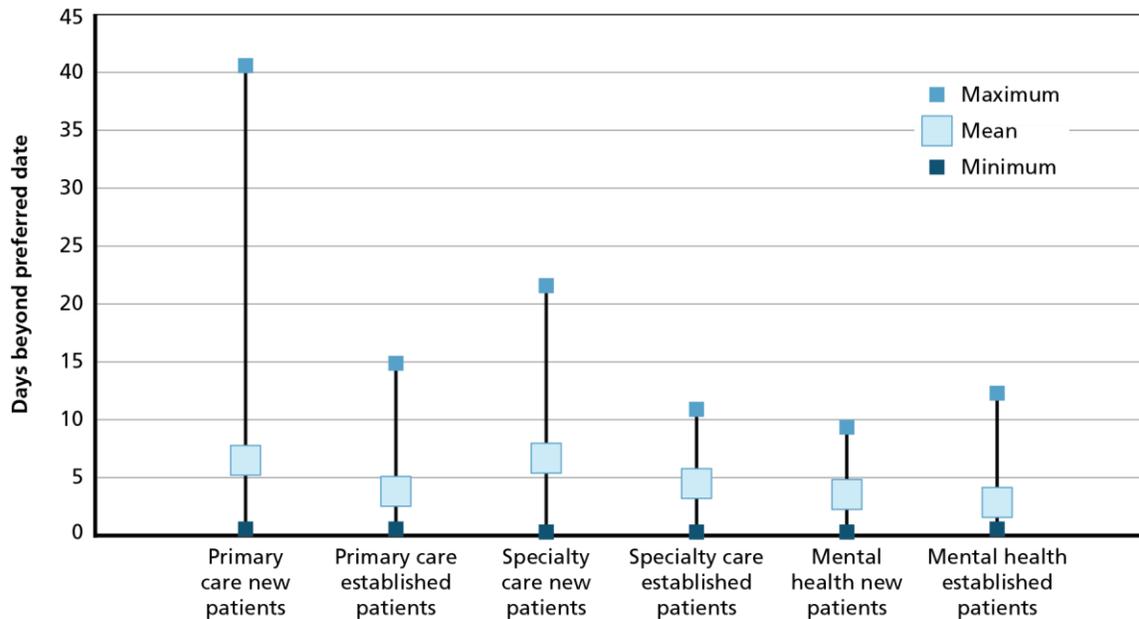
wait times, and extending of wait-time targets from 14 days to 30 days following preferred date, may have reduced the likelihood of VA employees tampering with VA's systems for recording of preferred dates.

Figure 4-15. Percentage of VA Appointments Completed Within 30 Days of Preferred Date, First Half of FY 2014 and First Half of FY 2015


Source: Authors' analysis of VA wait-time data for first half of FY 2014 and the first half of FY 2015 obtained from the VSSC by The MITRE Corporation.

4.2.4 Variation in Wait Times Across VA Facilities

Wait times vary tremendously across VA facilities. For example, during the first half of FY 2015, the average number of days waited from preferred date ranged from less than one day (at the best-performing VA facility) to 41 days (at the worst-performing VA facility) for new primary care appointments, and from less than one day to 22 days from the preferred date for new specialty care appointments (Figure 4-16).

Figure 4-16. Variation Across VA Facilities in Number of Days Waited for an Appointment Following Preferred Date, First Half of FY 2015


Source: Authors' analysis of VA wait-time data for the first half of FY 2015 obtained from the VSSC by The MITRE Corporation.

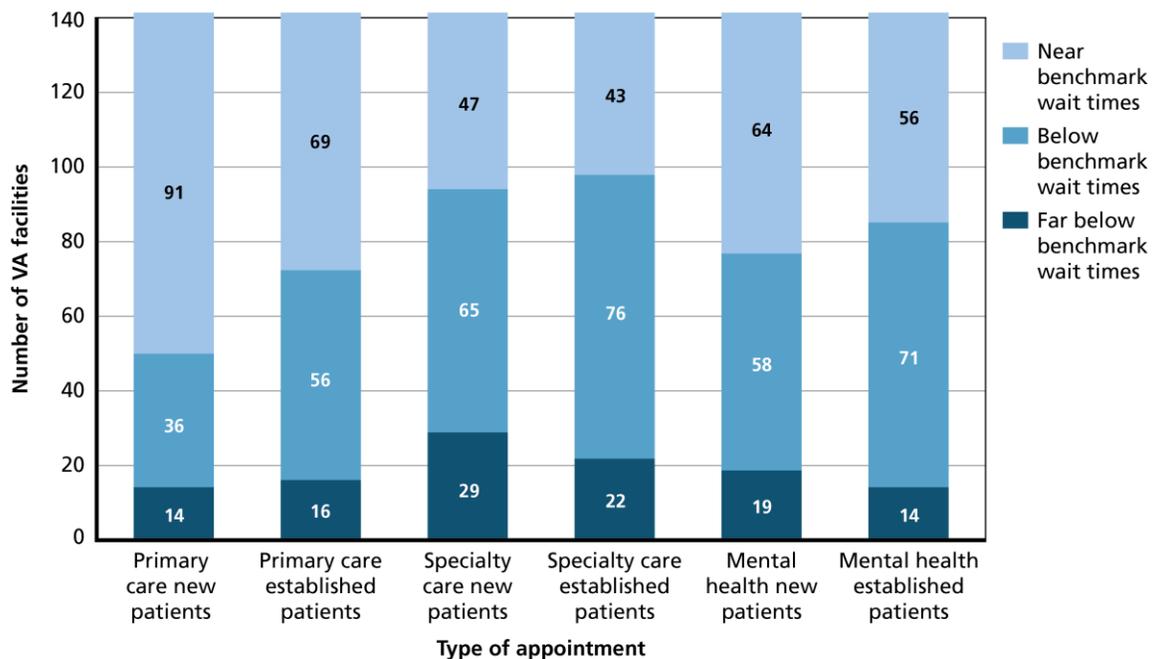
To compare across facilities, we estimated a benchmark for wait times for each appointment type. Although VA aims to complete 100 percent of appointments within the 30 days from preferred date threshold, no facilities achieved wait times of less than 30 days for 100 percent of Veterans for all types of appointments. Therefore, we set performance benchmarks to reflect wait times that VA facilities have demonstrated are achievable: the average wait time at the top-performing VA facilities, defined as the top 10 percent of facilities with regard to wait time for each appointment type. We then classified the performance of each facility into one of three categories relative to the benchmark: "near the benchmark" (within 0.5 standard deviation above or below the benchmark), "below the benchmark" (>0.5 to 2.0 standard deviations below the benchmark), or "far below the benchmark" (>2.0 standard deviations below the benchmark).[53]

Top-performing VA facilities achieve completed appointments within 30 days for virtually all of their new and established primary care, mental health care, and specialty care patients. The benchmarks for wait times for each appointment type (defined as the mean of the top 10 percent of facilities) were very high, ranging from 98.97 percent for established specialty care patients to 99.96 percent for new mental health care patients.

---

[53] Thresholds for achieving each of these benchmark categories for each appointment type are described in the notes for Figure 4-17.

More facilities fall far below the benchmark for specialty care than for primary care or mental health care appointments (Figure 4-17). Twenty-nine facilities were far below benchmark for specialty care appointments for new patients, 22 far below the benchmark for specialty care appointments for established patients, and 19 facilities far below the benchmark for mental health care appointments for new patients. In contrast, between 14 and 16 facilities were far below the benchmark for primary care appointments for new or established patients and mental health care appointments for established patients.

Figure 4-17. Number of VA Facilities with Wait Times Near, Below or Far Below Benchmarks, First Half of FY 2015, by Appointment Type


Source: Authors' analysis of VA wait-time data for the first half of FY 2015 obtained from the VSSC by The MITRE Corporation.
Notes: During the first half of FY 2015, for primary care appointments for new (established) patients, the benchmark was 99.95 percent (99.74 percent), and facilities were categorized as near benchmark if the percentage of appointments completed within 30 days of preferred date was above 95.98 percent (98.22 percent); below benchmark if between 84.05 percent and 95.98 percent (93.68 percent and 98.22 percent); and far below benchmark if below 84.05 percent (93.68 percent). The corresponding benchmark was 99.16 percent (98.97 percent) for specialty care appointments for new (established) patients, and thresholds were above 96.90 percent (97.73 percent) for near benchmark, between 90.13 percent and 96.90 percent (94.00 percent and 97.73 percent) for below benchmark, and less than 90.13 percent (94.00 percent) for far below benchmark. The corresponding benchmark was 99.96 percent (99.62 percent), and thresholds for mental health appointments for new (established) patients were above 99.02 percent (98.51 percent) for near benchmark, between 96.21 percent and 99.02 percent (95.19 percent and 98.51 percent) for below benchmark, and less than 96.21 percent (95.19

percent) for far below benchmark.

Appendix F includes maps displaying the performance of each VA facility in March 2014 through October 2015 (first half of FY 2015) with reference to the benchmark.

4.2.5 VA Wait Times Compared with the Private Sector

There is no national data source for wait times in non-VA settings with which to compare VA wait times. In addition, the limited wait-time data available in the private sector use a measure that is not directly comparable to VA's: total number of days between trying to schedule an appointment and the appointment date rather than VA's number of days *following the preferred date*. We therefore cannot make any conclusive statements about whether wait times in VA are better or worse than they are in the private sector overall. However, if we make the assumptions that (a) the preferred date for new VA patients is set by patient preference (rather than by clinical determination), (b) new VA patients typically want an appointment as soon as possible (that is, a preferred date of the same day), and (c) Veterans' preferred dates are entered accurately, VA's reported wait times for new patient primary and specialty care are shorter than wait times reported in focused studies of the private sector.

A 2013 study of private-sector health care wait times in 15 major metropolitan markets assessed the average number of days between an initial call to make a new patient appointment and the appointment date. Across these markets, the average wait time for an appointment with a family physician was 19.5 days, ranging from a low of five days in Dallas to a high of 66 days in Boston; average waits for specialty care appointments for new patients ranged from 10 days for orthopedic surgery to 29 days for dermatology (Merritt Hawkins, 2014). A similar 2013 study in Massachusetts reported average waits of 39 days between an initial call to make a new patient appointment and the appointment date for family medicine, 50 days for internal medicine, and between 22 and 37 days for specialty appointments, with shortest specialty care waits for orthopedic surgery and longest for obstetrics and gynecology (Massachusetts Medical Society, 2013).

By comparison, for the first half of FY 2015, VA reports that across facilities, the average number of days that Veterans waited for new patient appointments was approximately six and a half days from the preferred date for both primary care and specialty care, ranging from less than one day (at the best-performing VA facilities) to 41 days for primary care and 22 days for specialty care (at the worst-performing VA facilities).

Private-sector wait times are calculated only for those physicians or facilities accepting new patients (for example, 51 percent of family medicine physicians and 45 percent of internal medicine physicians in the Massachusetts study). VA facilities do not have the option of turning away new patients, and so might be reasonably expected to have longer wait times. However, the most recent wait-time data reported by VA suggest that VA wait times may be shorter than the wait times reported in the limited literature we found for the private sector.

4.2.6 Veterans' Perspectives on Timeliness of VA Care

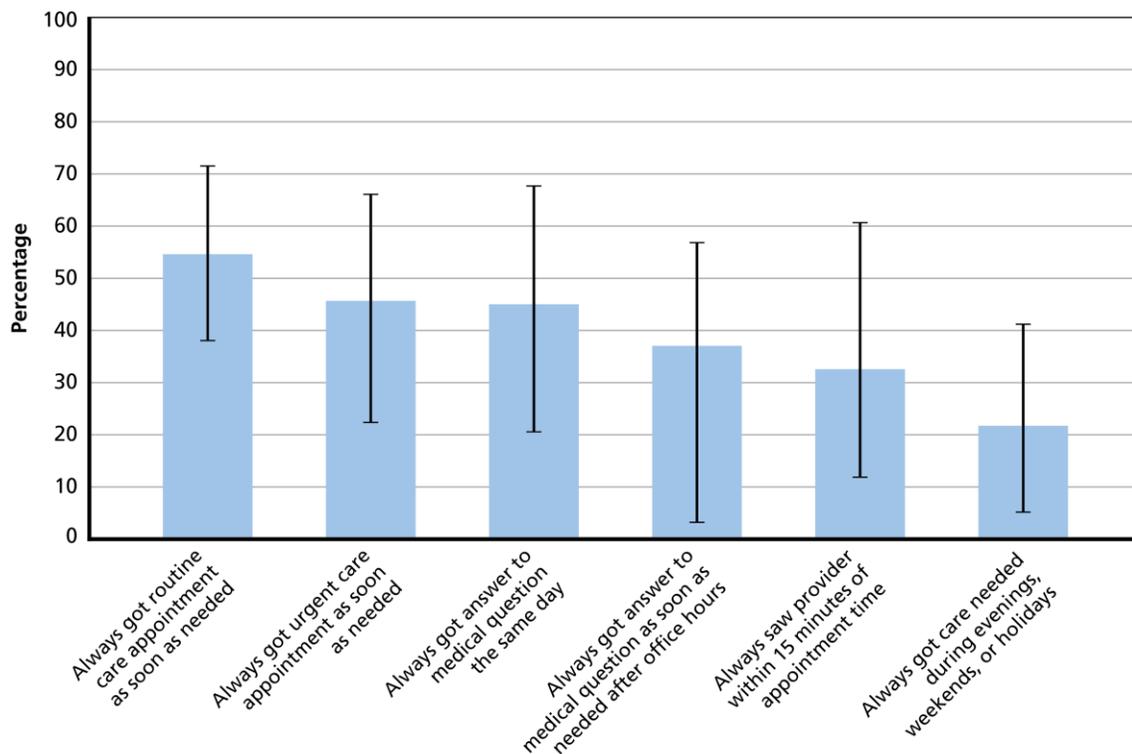
Veterans responding to the FY 2014 SHEP PCMH reported that they had better access to routine care than to urgent care from VA facilities. Most Veterans responding to the survey reported that they were not always able to get the care or information they need after hours.

Across VA facilities, the average proportion of Veterans responding to the SHEP PCMH who reported that they always got a routine care appointment as soon as needed was 55 percent (Figure 4-18); the corresponding proportion for urgent care appointments was 46 percent. At the top-performing VA facilities (defined as the top 10 percent of facilities for each question), the average proportions for routine and urgent care were 69 percent and 61 percent, respectively, suggesting considerable room for improvement for even the top-performing VA facilities.

The average proportion of Veterans reporting that they were always able to get the care they needed from the provider's office during evenings, weekends or holidays was 22 percent across VA facilities. Even at the top-performing VA facilities, only 36 percent of Veterans reported that they were able to do so.

Across facilities, an average of 45 percent of Veterans reported always getting an answer to a medical question the same day when they called their provider during regular office hours. The proportion reporting that they always got an answer to a medical question as soon as needed when calling the provider's office *after* regular office hours was 37 percent.

As shown in Figure 4-18, the difference in performance between the best and worst-performing VA facilities on each of the SHEP PCMH questions related to timely care, appointments, and information is very large, ranging from 36 percentage points between the best and worst facilities for seeing a provider within 15 minutes of the appointment time to 54 percentage points for getting an answer to a medical question the same day. For context, differences of as few as three to six percentage points on access-related questions on a CAHPS health plan survey have been associated with substantial differences in rates of voluntary disenrollment from Medicare plans (Lied et al., 2003).

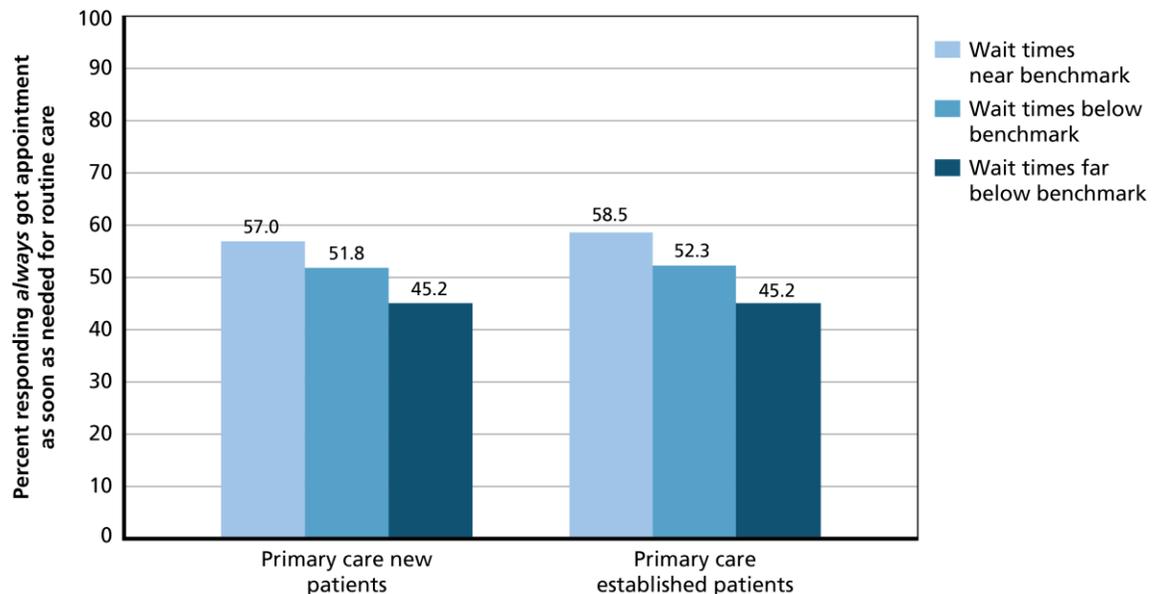
Figure 4-18. VA Facility Average of Percent of Veterans Responding "Always" to Access Questions on the SHEP PCMH, FY 2014


Source: Facility-level patient experience data for VA patients from the SHEP PCMH in FY 2014 obtained from the VA Office of Performance Measurement.

Notes: The height of the bar is equal to the mean percentage of patients who responded "always" to each question. The line extending from the top of the bar represents the range of values at the VA facility level, from the minimum (worst-performing facility) to the maximum (best-performing facility).

As noted above, VA wait-time metrics do not allow for precise tracking of the absolute number of days that Veterans wait for appointments. However, our analysis of Veterans' SHEP reports suggests that VA-reported wait times are an accurate indicator of the *relative* timeliness of appointments across VA facilities. Veterans who receive care from VA facilities with longer wait times report worse experiences of access than those who receive care from facilities with shorter wait times (Figure 4-19). For example, the average proportion of Veterans who reported that they "always" got an appointment as soon as needed for routine care was statistically significantly higher for facilities with the shortest wait times for new primary care patients (near benchmark) than for facilities below the benchmark; the same pattern is true between facilities below the benchmark and those far below the benchmark. The pattern of results was similar for all SHEP questions regarding timely care, appointments and information and for wait times for all types of appointments.

Even at the facilities with the shortest wait times, fewer than three in five Veterans report that they "always" get an appointment as soon as needed, suggesting that even facilities that achieve VA's wait-time standards do not meet many Veterans' expectations for timely appointments.

Figure 4-19. Percentage of Veterans in VA Facilities Responding That They "Always" Got Appointment for Routine Care as Soon as Needed, by Performance on Primary Care Wait Times


Sources: Benchmark categories were established by authors' analysis of VA wait-time data for the first half of FY 2015 obtained from the VSSC by The MITRE Corporation. Facility-level patient experience data for VA patients from the SHEP PCMH in FY 2014 were obtained from the VA Office of Performance Measurement.
Note: Statistical significance was determined based on t-tests for pairwise differences with Bonferroni adjustment for multiple comparisons.

Once Veterans are in a VA facility to attend scheduled appointments, most wait longer than 15 minutes. Across facilities, the average proportion of Veterans responding to the SHEP PCMH in FY 2014 who reported always seeing a health care provider within 15 minutes of their appointment time was 33 percent; the average proportion at the highest-performing VA facilities was 46 percent. Since 2010, the proportion of Veterans responding to the Survey of Enrollees who either completely agreed or agreed that Veterans like them can get in and out of a VA appointment in a reasonable time has declined substantially (from 73 percent in 2010 to 65 percent in 2014), suggesting that Veterans perceive that in-facility waits for appointments have worsened over time. In-facility wait times are important to Veterans: in online Yelp reviews of VA facilities, 6 percent of reviewer comments were regarding long wait times within VA facilities once Veterans arrived for scheduled appointments, making such complaints among

the top 10 most common types of comments about VA facilities. An additional 3 percent of comments complimented the VA facility for a short wait for an appointment once at the facility.

4.2.7 Veteran Reports Regarding Timeliness of Care Compared with the Private Sector

There are no nationally representative data with which to compare SHEP PCMH results.[54] However, VA's SHEP PCMH survey contains the same measures as the CAHPS Clinician & Group PCMH Survey that is used widely throughout the United States to collect information on patients' experiences with care. The CAHPS Database hosted by the AHRQ contains comparative data for this survey from medical practices that volunteer to submit their survey responses (AHRQ, n.d.). The most recent year of the CAHPS Database available at the time of this report, 2013, includes results from 833 participating practice sites administering the CAHPS Clinician & Group PCMH Survey (AHRQ, 2014). These practices do not constitute a representative sample of all medical practices in the United States, and given their willingness to voluntarily submit their scores, high-performing practices are likely over-represented. The practices differ from the complete set of VA facilities for which we report performance. Therefore, we compare the performance of the *top-performing VA facilities* in FY 2014 with the *average performance of the Database practices* in 2013 to examine the relative strengths and weakness of top-performing VA and non-VA facilities. Since some CAHPS Database practices may not be high performers, we also compare the performance of the *75th percentile of VA facilities* for each measure with the *average performance of the Database practices*.

We were not able to adjust the CAHPS Database survey scores to account for factors such as respondents' age, sex, self-reported health and mental status, or education, which have been shown to be associated with reporting systematically higher or lower responses on patient experience surveys (Zaslavsky et al., 2001; Hargraves et al., 2001; Elliott et al., 2009). Our analyses of inpatient SHEP data, described in Section 5, suggest that adjusting for these factors may account for differences of up to three percentage points in either direction between reports of patient experience from SHEP and those from a comparable CAHPS survey.[55] Thus, if differences between VA SHEP scores and CAHPS Database scores are greater than three percentage points, they are unlikely to be explained by patient mix alone. Here, we consider differences of up to three percent between scores of high-performing VA facilities and average CAHPS Database practices as comparable performance, and differences greater than three percent to indicate truly higher or lower performance.

Taking into account this three percent margin, *top-performing VA facilities* were comparable to *average practices* in the CAHPS Database, but the 75th percentile of VA facilities performed substantially worse than average CAHPS Database practices, with regard to the proportion of patients reporting that they always got a routine care appointment as soon as needed (69

---

[54] National scores are available for the CAHPS Health Plan Survey and Medicare CAHPS surveys; however, the measures on these surveys are not the same as those on the SHEP PCMH.

[55] As reported in Section 5, the adjustment may account for an average of 4 points for overall ratings of care.

---

percent for top-performing VA facilities and 61 percent for the 75th percentile of VA facilities versus 72 percent for CAHPS Database practices) and saw their provider within 15 minutes of their appointment time (46 percent and 39 percent versus 49 percent, respectively).

Across VA facilities, Veterans responding to the SHEP PCMH at *top-performing VA facilities* and t*he 75th percentile of VA facilities* were substantially less likely than surveyed patients in CAHPS Database practices to report that they always got an appointment for urgent care as soon as needed (61 percent at top-performing VA facilities and 52 percent at the 75th percentile of VA facilities versus 67 percent for CAHPS Database practices), got an answer to a medical question the same day when they phoned their provider's office during regular office hours (59 percent and 51 percent versus 64 percent, respectively), and got an answer to a medical question the same day when they phoned their provider's office *after* regular office hours (55 percent and 44 percent versus 64 percent, respectively).

4.2.8   Subsection Summary

The average number of days that Veterans wait for appointments varies tremendously across VA facilities, indicating substantial opportunities for improvement in some facilities. Most Veterans complete their appointments within VA timeliness standards of within 30 days of the preferred date. However, Veterans who do not receive care within 30 days may be at risk of poor health outcomes. Further, VA's timeliness standard is much less demanding than alternative standards that have been proposed in the private sector. The standard is also sensitive to the definition of the "preferred date," which has been subject to gaming. For example, the VA Inspector General found that VA staff regularly entered false information regarding preferred dates of care. Alternative standards, such as those that assess availability rather than completion of appointments, may be less subject to gaming and more comparable to private-sector standards.

Even at the facilities with the shortest wait times, many Veterans report that they do not always get an appointment as soon as needed, suggesting that even these top-performing facilities do not meet many Veterans' expectations for timely appointments. Veterans are substantially less likely than patients in private-sector practices to report that they got appointments, care, and information as soon as they needed.

4.3   Financial Access

4.3.1   Veterans' Out-of-Pocket Costs for VA Care

Although Veterans do not pay premiums to enroll in VA care, some of them do face out-of-pocket costs. Copayments for VA health care services vary by the priority group of the Veteran (VA, 2015h; VA, 2015i) though even within priority groups, Veterans can face differing copayment levels for a variety of reasons, including reason for enrollment, severity of disability,

and income.[56] In 2015, those in priority group 1 have no copays. For reference, Assessment A reports that as of 2013, Veterans in priority group 1 made up more than a quarter (27 percent) of all users of VA health care. Copayments for non-service connected care for primary care visits ($15 per visit), specialty care visits ($50 per visit), care from a Community Living Center (up to $97 per day), adult day health care (up to $15 per day), or domiciliary care ($5 per day) are the same for those in priority groups 2 through 8 for those Veterans who have to pay them. Veterans in groups 2 through 6 have increased financial protection for medications, facing copays of $8 for each 30-day or less supply of medications and a $960 annual out-of-pocket maximum. Veterans in groups 7 and 8 pay copays of $9 for these medications and face no annual out-of-pocket maximum. While inpatient care is free to those in groups 2 through 6, out-of-pocket payments for inpatient stays are required from Veterans in groups 7 and 8. For reference, Assessment A reports that as of 2013, Veterans in priority groups 7 and 8 made up 22 percent of all users of VA health care.

By comparison, in 2014, individuals with employer-sponsored health insurance paid copays of $24 for primary care and $36 for specialty care visits with in-network providers and between $11 and $83 for each 30-day supply of medication, depending on drug type (Kaiser Family Foundation & Health Research & Educational Trust, 2014).[57]

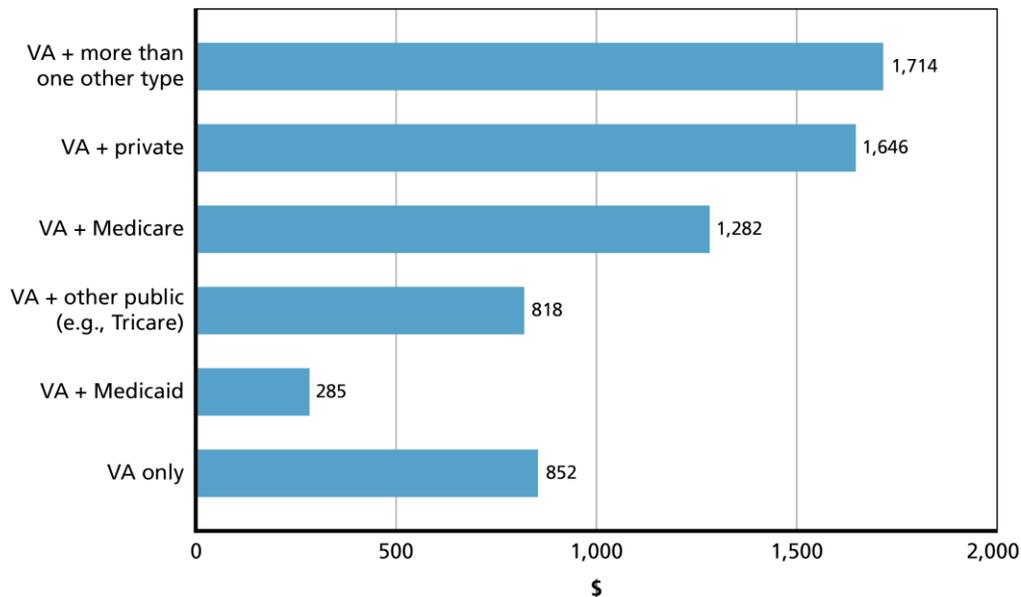
Figure 4-20 displays data from the 2012 Medical Expenditure Panel Survey on annual out of pocket payments for Veterans who use VA care. Out-of-pocket costs were lowest for those with both VA and Medicaid coverage ($285) or VA and other public insurance, such as Tricare ($818). Higher out-of-pocket payments among those with VA and Medicare ($1,282), VA and other private health insurance ($1,646), and VA and more than one other type of coverage, such as both Medicare and employer-sponsored insurance ($1,714), likely indicate that these Veterans rely less on the VA system and are therefore paying the Medicare or private health insurance cost sharing. By comparison, in 2012, individuals with employer-sponsored health insurance paid an average of $951 toward their premiums for individual coverage (Kaiser Family Foundation & Health Research & Educational Trust, 2014) plus additional out-of-pocket costs for copays and coinsurance. In 2012, average outlays for copays and coinsurance for non-Veterans ranged from $742 for those with private insurance only to $1,049 for those with more than one other type of coverage, such as both Medicare and employer-sponsored insurance

---

[56] This report offers a high-level summary of copayments. Copayments for individual Veterans may vary for a number of reasons. For example, there are a variety of exemptions to copayment requirements for non-service connected care. Veterans can exempted from copayments if their incomes are below specified thresholds depending on location. More information on geographic means tests can be found here: http://www.va.gov/healthbenefits/resources/publications/IB10-497_means_test_gmt_and_pension_threshold_nov14.pdf. Copayments also vary on whether the service is related to a clinical trial and the Veterans' eligibility reason for VHA services, even within priority group, particularly for services such as medications. For more detailed information on copayments for medications for specific groups, please see: http://www.va.gov/healthbenefits/resources/publications/IB10-336_medication_copay_brochure_apr2014.pdf.

[57] Some individuals with employer-sponsored health insurance face coinsurance instead of copays for prescription drugs, often depending on drug type.

(authors' analysis of 2012 Medical Expenditure Panel Survey data). Comparisons between Veteran and non-Veteran total out-of-pocket costs should be made with caution given differential patterns of service use between the two groups.

Figure 4-20. Annual Out-of-Pocket Payments Reported by VA Users in 2012, by Insurance Type


Source: Authors' analysis of 2012 Medical Expenditure Panel Survey data.

4.3.2   Cost Factors Related to Enrollment and Reliance on VA

Most Veterans—particularly unemployed Veterans, those with low incomes, and those without other health insurance—believe that VA health care is their most cost-effective option. In 2014, approximately two-thirds of Veterans responding to the Survey of Enrollees indicated that they completely agreed or agreed that if the cost of health care increases, they would use VA more, that VA offers Veterans like them the best value for their health care dollar, and that VA is the most cost-effective provider for Veterans like them. Low-income Veterans (those with incomes under $36,000 per year) and those who were unemployed were significantly more likely than Veterans with higher incomes or employment to report that their use of VA would decrease if their financial resources improved. Twenty-eight percent of Veterans indicated that their use of VA would decrease if their financial resources improved. This suggests that for a substantial minority of Veterans, non-VA care is preferred if available. In interviews, VA administrators and representatives of Veteran Service Organizations noted that Veterans generally like to get their care from VA, but that some Veterans with affordable non-VA care options seek care elsewhere rather than dealing with challenges associated with determining their eligibility for services and seeking reimbursement, facing real or perceived long VA wait times, undergoing the inconvenience of making appointments with automated telephone systems or call centers, and

receiving care in VA settings that are less likely to have the amenities and state-of-the art equipment of the private sector.

VA health care workers interviewed by RAND noted that lack of an affordable private insurance option is a key reason why Veterans enroll in VA. This finding is in keeping with prior studies, which have reported that Veterans seek VA care due to its low cost relative to their other coverage alternatives (Jonk et al., 2005; Washington, Yano, Simon & Sun, 2006; Nelson et al., 2007; Petersen et al., 2010; Nayar et al., 2013).

Veterans with access to both VA services and other sources of health care, such as Medicare display a mixed pattern of utilization, relying on VA for some types of care and on additional sources of insurance for other care (West & Weeks, 2007; Liu et al., 2010). Some of this mixed utilization is likely due to the relative cost of care between VA and the Veteran's alternative source of health care coverage.

Unemployment and lower income status are both independently associated with an increased reliance on VA services (Jonk et al., 2005; Washington, Yano, Simon, & Sun, 2006; Fillenbaum et al., 2007; Nelson et al., 2007; Petersen et al., 2010), likely due in part to the demand for lower cost health care services among unemployed and lower income Veterans.

Potential impacts of the Affordable Care Act on reliance on VA are described in Assessment A.

4.3.3   Subsection Summary

VA is often Veterans' most affordable option for health care coverage. Veterans typically face lower out-of-pocket costs for care in VA than they would if they were privately insured. Lack of an affordable private insurance option is a key reason why Veterans enroll in VA.

4.4   Digital Access

As described in Section 1, digital access refers to connectivity that enables Veterans to engage in digital communications with providers, caregivers, peers, and computerized health applications. Section 3 described the range of digital services available within VA and rates of use of those services. Here, we describe the degree to which Veterans have access to digital channels of communication which enable them to access these services.

Thirty percent of Veterans responding to the 2013 Survey of Enrollees reported that they do not access the Internet. Of those Veterans who did report access, nearly 9 of 10 access the Internet from home, while the remainder accesses it from a variety of locations, including public libraries (2 percent). Interviews with VA health care providers and RAND analyses of Survey of Enrollees data suggest that older Veterans are significantly less likely to have Internet access. VA health care providers also note that older Veterans may lack knowledge required to access VA's digital services, such as VA's personal health record, MyHealtheVet, or telehealth. In the coming decades, Internet access and technological skill are likely to grow more common among Veterans, thereby increasing the acceptability and accessibility of digital health care services.

4.5   Cultural Access

As noted in Section 1, cultural access refers to the acceptability of health services to the patient. Acceptability may be driven by factors that are similar for all Veterans, such as military culture, or may vary by Veteran characteristics, including sex, race, ethnicity, sexual orientation, gender identity, and medical diagnosis. Cultural acceptability of VA care varies by Veteran characteristics.

Some Veterans prefer to seek VA care because it provides them an opportunity to spend time with other Veterans. The sense of camaraderie that Veterans feel among other Veterans at VA facilities was one of the top 20 themes the RAND identified in analysis of online Yelp reviews of those facilities. Additionally, in interviews, administrators and health care workers emphasized the importance of Veterans receiving care from providers who understood their experience, and of VA's provision of services that provide a sense of a community for Veterans, such as events to welcome home returning service members. As of 2014, over half (55 percent) of Veterans responding to the Survey of Enrollees reported that they either completely agreed or agreed that Veterans like them like to go to VA because they like to talk to other Veterans. From 2010 to 2014, the percentage of Veteran enrollees who either completely agreed or agreed that VA health care providers treat them with respect declined from 88 to 81 percent. Some VA health care providers we interviewed noted that while efforts are being made to ensure that providers as sensitized to the unique experience of Veterans, more could be done to increase awareness of military-specific language and slang, as well as the changing demographics among Veterans.

Subgroups of Veterans that may face particular cultural barriers to access include racial and ethnic minorities, and groups that have traditionally been underrepresented in VA, such as women.

Experts have suggested that gender-sensitive comprehensive care for female Veterans includes provision of gender-specific care, such as female reproductive health services, awareness of best practices for management of women's health, and gender sensitivity, including attention to female Veterans' care preferences (deKleijn et al., 2015). With regard to provision of gender-specific care, increased attention to the needs of female Veterans has led to broad access to basic reproductive health services; however, access to more advanced services, such as gynecologic surgery and placement of contraceptives, is more variable by location (Washington, Yano, Goldzweig, & Simon, 2006; Yano et al., 2006; Seelig et al., 2008; Cordasco et al., 2013; Katon et al., 2013). With regard to gender sensitivity, VA health care workers indicated in interviews that additional steps could be taken by providers to ensure that female Veterans feel respected while receiving care in VA facilities. In keeping with these interview findings, female Veterans responding to the Survey of Enrollees are significantly less likely than male Veterans to agree that VA health care providers treat patients with respect.

Approximately 3–5 percent of Veterans report racial discrimination by health care providers; the proportion reporting perceived discrimination is similar among Veterans who use VA care and Veterans who use non-VA care (Hausmann et al., 2009). However, evidence regarding access to VA care for Veterans in various racial and ethnic groups is mixed. For example, studies

have reported that black Veterans were less likely than white Veterans to receive an effective treatment for severe depression (Pfeiffer et al., 2011) or heart drugs and procedures (Mehta et al., 2010) at VA facilities, while other studies have found comparable care for black and white Veterans at VA facilities with regard to timely colon cancer surgery (Robinson & Petzel, 2010) and total joint replacement (Hausmann et al., 2010). Earlier studies have found that Native American and Alaska Native Veterans report significantly more unmet health care needs than white Veterans (Kramer, 2009), and face unique challenges to access within VA, including assistance in coordinating care between VA and the Indian Health Service (Villa, Harada, & Huynh-Hohnbaum, 2010).

Observed racial and ethnic disparities in VA health care may be due, in part, to differences with regard to knowledge of medical information, trust in medical interventions and health care providers, participation in shared decision-making, level of social support, clinicians' judgment, and the quality of VA facilities attended (Health Services Research & Development Service, 2007).

Homeless Veterans treated at VA-staffed transitional residential treatment programs had similar patient satisfaction scores and outcomes at 12 months as Veterans treated at two community-based programs (McGuire, Rosenheck, & Kasprow, 2010), suggesting that VA care may be as acceptable to homeless Veterans as other alternative care settings.

Finally, with respect to sexual orientation and gender identity, one study found that lesbian, gay, and bisexual Veterans avoid seeking VA care due to concerns that they would be stigmatized for their sexual orientation (Simpson et al., 2013). In contrast, another study found a sharp increase in the number of transgender Veterans using VA care over the past several years, suggesting a response to a 2011 VA national directive to standardize treatment services for transgender Veterans (Kauth et al., 2014).

4.6   Section Conclusion

Although we did not find evidence of a system-wide crisis in access to VA care, our assessment found considerable variability across the different dimensions of access, including important barriers to be addressed.

Geographic access. Veterans are highly dispersed geographically throughout the United States, and ensuring nearby access to needed services for this population is difficult. Many Veterans have geographic access to VA care by a general standard of less than 40 miles distance from any facility, not considering the services available at that facility. However, geographic access is worse when using different types of access standards, such as reliance on public transportation. Geographic access to specialized facilities and providers is also lower. Ensuring geographic access to purchased care is also a challenge.

Timeliness. The average number of days that Veterans wait for appointments varies tremendously across VA facilities. Most Veterans complete their appointments within VA timeliness standards of within 30 days of the preferred date. However, Veterans who do not receive care within 30 days may be at risk of poor health outcomes. Further, VA's timeliness

standard is much less demanding than alternative standards that have been proposed in the private sector.

Financial access. VA is often Veterans' most affordable option for health care coverage. Veterans typically face lower out-of-pocket costs for care in VA than they would if they were privately insured. Lack of an affordable private insurance option is a key reason why Veterans enroll in VA.

Digital access. Many Veterans, especially older Veterans, do not have access to the Internet, and therefore cannot access VA's digital services. As younger Veterans age, Internet access and technological skill are likely to grow more common among Veterans, thereby increasing the acceptability of digital health care services.

Cultural access. Cultural acceptability of VA care varies by Veteran characteristics, including sex, race, ethnicity, sexual orientation, gender identity, and medical diagnosis. Some VA health care providers noted that, while efforts are being made to ensure that providers as sensitized to the unique experience of Veterans, more could be done to increase awareness of military-specific language and slang, as well as the changing demographics among Veterans.

When Veterans do access VA care, it is important that the care be of high quality. In the next section, we turn the focus to the quality of VA care.

5   Assessment of Quality of VA Care

Assessing the quality of VA care is an integral part of assessing Veterans' access to care. In a memorandum to VA leadership, the Interim Under Secretary for Health for VA described the purpose of the independent assessments of the Veterans Affairs Health Care Delivery systems and Management Processes collectively as a comprehensive evaluation of "VA's ability to deliver high-quality health care to Veterans" (Clancy, 2014). As a result of this emphasis on high-quality care for the assessments, RAND designed Assessment B to characterize current VA quality of care by conducting a systematic review of previous studies of VA quality compared with non-VA providers and comparing VA and non-VA performance on quality measures.

In this section, we present the findings from our assessment of the quality of health care provided by VA to Veterans. We organize results according to the domains of quality outlined by the Institute of Medicine (safety, timeliness, equity, effectiveness, efficiency, and patient-centeredness) and described in Subsection 1.4.2 of this report. These domains are defined as follows (Institute of Medicine, 2001):

- Safety: Avoiding injury to patients from the care intended to help them
- Timeliness: Reducing wait times for both providers and patients
- Equity: Providing care that does not vary in quality because of personal characteristics such as gender, race/ethnicity, and socioeconomic status
- Effectiveness: Providing evidence-based services to those who could benefit, and not giving services to those unlikely to benefit
- Efficiency: Avoiding waste, including waste of equipment, supplies, ideas and energy
- Patient-centeredness: Providing care that is responsive to individual patient preferences, needs and values.

For each domain, we summarize the results of published studies that compare the quality of care provided by VA and non-VA health care systems, and present the results of our analyses of the latest data on VA performance on quality measures. We show how VA is performing at the national level and how performance varies at the facility level and, whenever possible, indicate how VA performance compares to non-VA care.

A summary of the methods used in these analyses is shown in the box.

The views, opinions, and/or findings contained in this report are those of RAND Corporation and should not be construed as an official government position, policy, or decision.

Overview of Methods and Data for Assessment of Quality of VA Care

- We conducted a systematic literature review to examine how the quality of VA care compares to non-VA care.
- Safety of care focused on adverse events in the inpatient setting and was measured using AHRQ Patient Safety Indicator data from VA and CMS Hospital Compare.
- Effectiveness of outpatient care focused on screening, prevention, and wellness; chronic condition management; comprehensive diabetes care; cholesterol management for patients with cardiovascular conditions; and antidepressant medication management; and was measured using HEDIS quality measure data from VA and NCQA. We compared VA performance rates with those for commercial, Medicaid, and Medicare health plans, as reported by the NCQA State of Health Care Quality Report.
- Effectiveness of inpatient care focused on care processes for selected conditions (for example, ORYX measures for acute myocardial infarction, pneumonia, heart failure) and was measured using data from CMS Hospital Compare for VA and non-VA facilities.
- Patient-centeredness of care focused on Veterans' reports of outpatient and inpatient care experiences (for example, communication with health care providers and staff, self-management support) and was measured using data from VA SHEP PCMH, VA inpatient SHEP, and CMS Hospital Compare.
- We compared mean performance and analyzed variation in quality measures across VA facilities and non-VA facilities.
- For complete details of the methods used to assess quality of VA care, please refer to Section 2 and Appendix A, Subsection A.5.

5.1 Evidence from Previous Studies of Quality of VA Care

Below, we present results from 34 studies on safety, one on timeliness, four on equity, 24 on effectiveness, nine on efficiency, and five on patient-centeredness. We organize the results in this subsection by these dimensions, with findings from some articles appearing in multiple subsections (if the article covers multiple quality dimensions). All of the results summarized below are adjusted for some combination of risk, comorbidities, demographics, or other variables when appropriate, unless otherwise specified. This systematic review updates a previous systematic review that compares the quality of care delivered in VA versus non-VA performed on this topic (Asch et al., 2010). Therefore, we chose to build on this work using consistent methods, including the same search terms (see Appendix A for detailed methods). All studies included in the previous review published after 2005 are also included in the current review.

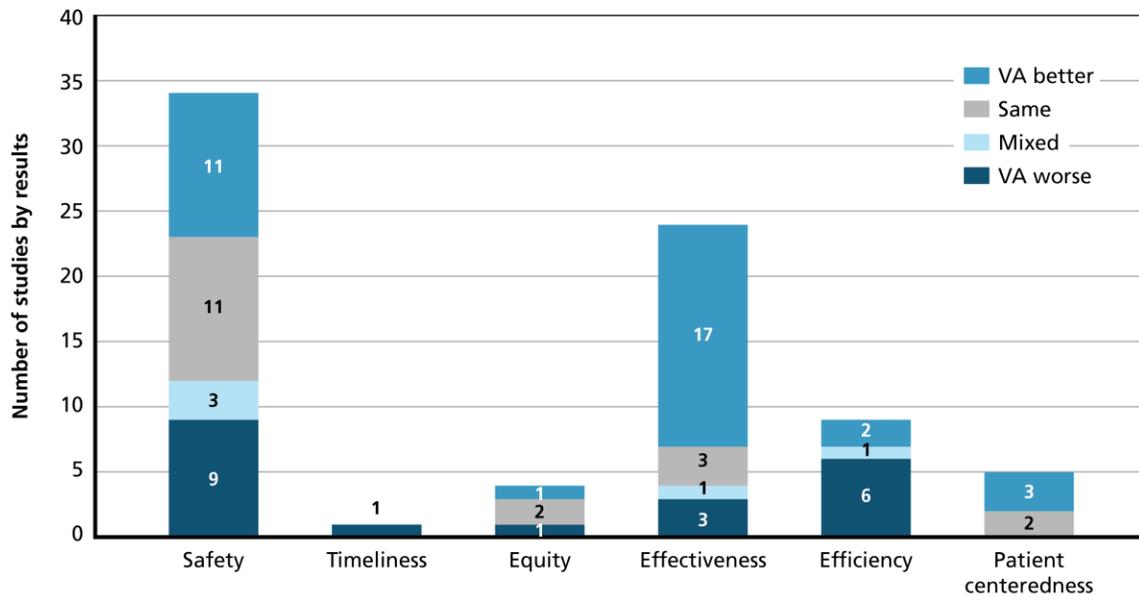
We classified each study in the review according to the statistically significant differences in performance on quality of care measures for VA care relative to a non-VA comparison group (Figure 5-1). If VA quality of care was shown to be better than quality for non-VA care, the study

---

was classified as "VA better." If multiple results were reported for a study and VA quality of care was better in some instances and the same in other instances compared with non-VA care, the study was also classified as "VA better." If multiple quality measures were reported in the study and VA care was better than non-VA on some and worse on others, the study was classified as "mixed." If the quality of care in VA and non-VA did not differ, the study was classified as "same." If VA quality of care was shown to be worse than non-VA, the study was classified as "VA worse" (as were studies with multiple results reported where the quality of care was worse in some instances and the same in other instances).

VA facilities performed inconsistently in studies related to safety, with 11 studies showing better performance, 11 showing same performance, three showing mixed performance, and nine showing worse performance (Figure 5-1). Only one study assessed timeliness of care in VA facilities, showing worse performance than the non-VA facilities. In terms of equity, VA settings demonstrated better performance in one article, same performance in two articles, and worse performance in one article compared with non-VA settings. VA facilities performed well in studies of effectiveness, with 17 studies showing better performance, three showing same, one mixed, and three worse. The articles (nine) that evaluated measures of efficiency, such as hospital length of stay, demonstrated better (two), mixed (one), or worse (six) performance in VA facilities compared with non-VA facilities. Only five articles looked at patient-centeredness quality measures, but all demonstrated better (three) or same (two) VA care quality compared with care in non-VA settings.

In the following subsections, more information is provided about these studies. Almost all the studies compare Veterans receiving VA care with individuals who are not identified as Veterans in the studies (referred to as "non-Veterans") and who received care outside of the VA system (referred to as "non-VA care"). However, a few studies are included that compare Veterans receiving VA care with Veterans receiving non-VA care. These two types of studies differ in terms of the similarity of the characteristics of the comparison populations. The first group of studies compares Veterans and non-Veterans, so the patients may differ in ways related to the Veteran experience. The second group of studies compares Veterans receiving two types of care, so they may be similar in ways related to the Veteran experience. Therefore, we labeled these clearly to alert the reader to the difference.

Figure 5-1. Number of Studies in Systematic Review, by Quality Dimension and VA Performance, Compared with Non-VA


Source: RAND systematic review of studies on quality of care in VA compared with non-VA settings.

Notes: Categories are defined as follows: VA better = VA quality of care shown to be better than non-VA, or a mix of same and better; mixed = for studies with multiple quality measures, VA care was better than non-VA on some and worse on others; same = quality of care in VA and non-VA did not differ; VA worse = VA quality of care was shown to be worse than non-VA, or a mix of worse and same.

5.1.1 Safety of Care in VA Compared with Non-VA

Safety measures focus on topics related to avoiding injuries to patients from the care that is intended to help them, such as complications following surgical procedures. Also included in this category are mortality rates among those receiving care in VA or non-VA settings. In 22 of 34 comparisons, VA generally performed as well as or better than other settings in terms of complications, morbidity, and mortality. VA patients fared worse in nine studies and had mixed experience (some better and some worse) in three studies.

Surgical complication rates were similar among Veterans at VA and non-Veterans receiving non-VA care following several types of surgery (Boitano, Wang, & Kibbe, 2012; Henderson et al., 2007; Weiss et al., 2006). Lower mortality and higher complication rates were observed for cataract surgeries for Veterans who are VA patients compared with Veterans who are Medicare fee-for-service beneficiaries (French & Margo, 2012; French et al., 2012b). Postoperative morbidity was lower for VA patients compared with non-Veterans receiving non-VA care (Fink et al., 2007; Hutter et al., 2007; Johnson et al., 2007). In several studies, morbidity after several types of surgery did not differ between VA patients and non-Veterans receiving non-VA care (Hall et al., 2007; Lancaster et al., 2007; Lautz et al., 2007; Neumayer et al., 2007; Turrentine et al., 2007), but was worse for VA patients overall (Glasgow et al., 2007) and male VA patients (Lautz et al., 2007). In studies comparing quality of care for Veterans receiving VA care and non-VA care, Veterans residing in VA nursing homes were less likely to develop a pressure ulcer than Veterans in community nursing homes (Berlowitz et al., 2005). VA hospitals were more likely to follow best practices in the use of central venous catheter bloodstream infection prevention compared with non-VA hospitals (Krein et al., 2007). Performance on AHRQ's patient safety indicators was found to be a mix of higher, lower, and similar rates at VA hospitals compared with non-VA hospitals (Rosen et al., 2005; Weeks et al., 2008b; Rivard et al., 2010). Among all kidney transplant recipients, VA patients had a higher risk for graft failure than non-Veterans receiving non-VA care (Chakkera et al., 2004).

Mortality rates associated with specific conditions (Fihn et al., 2009; Landrum et al., 2012; Tarlov et al., 2012) or following surgical procedures (Bilimoria et al., 2007; Boitano, Wang, & Kibbe, 2012; Choi et al., 2009; Fink et al., 2007; Hutter et al., 2007; Weiss et al., 2006) were similar for Veterans receiving VA care compared with non-Veterans receiving non-VA care. Rates of mortality declined more quickly in VA over time than in non-VA settings (Borzecki et al., 2010). Veterans treated in VA and non-VA settings also experienced similar mortality rates (Wang et al., 2013a; Berlowitz et al., 2005). Adjusted mortality was lower among Veterans who used VA care compared with male Medicare Advantage beneficiaries over 65 years of age (Selim et al., 2010; Selim et al., 2009; Selim et al., 2006; Selim et al., 2007). Mortality after some surgeries was higher among VA patients compared with non-Veterans receiving non-VA care (Campling et al., 2005; Chakkera et al., 2004; Glasgow et al., 2007; Henderson et al., 2007; Vaughan-Sarrazin, Wakefield, & Rosenthal, 2007) and after other surgeries, similar (Vaughan-Sarrazin, Wakefield, & Rosenthal, 2007). Mortality within one year of admission after hip fracture was 21 percent lower among Veterans admitted to non-VA hospitals compared with Veterans admitted to VA hospitals (Richardson et al., 2013).

5.1.2   Timeliness of Care in VA Compared with Non-VA

Only one study addressed timeliness of care in VA facilities relative to non-VA facilities. This study observed a significantly shorter time between hospital admission for hip fracture and surgical repair of hip fracture for Veterans admitted to non-VA hospitals compared with VA hospitals (Richardson et al., 2013); the shorter time interval indicates the care was better in non-VA hospitals.

5.1.3   Equity of Care in VA Compared with Non-VA

Equity measures focus on comparing quality between patients with different personal characteristics, such as females compared with males. VA performance on equity measures was better than or the same as non-VA care, in three studies comparing disparities within VA patients and non-VA patients; one study showed worse performance. In the largest study, Trivedi et al. (2011) observed significantly narrower income and educational disparities for nine of 12 quality measures assessing diabetes, cardiovascular, and cancer screening care in VA patients compared with Medicare Advantage enrollees. Polsky et al. (2007) found the patterns of racial differences in 30-day mortality rates after hospital admission for several conditions were similar for Veterans in VA hospitals and non-Veterans in non-VA hospitals, with African Americans age 65 years and older having significantly reduced odds of 30-day mortality for almost all conditions. (Chakkera et al., 2004) showed that African-American race was associated with an increased risk of graft failure, a pattern observed among both Veterans receiving VA care and all patients receiving non-VA care. One study had worse results. In a study of end-of-life care for older cancer patients, Keating et al. (2010) found no significant differences between African-American and white patients in chemotherapy use and ICU admissions for either VA or Medicare patients, but African Americans were more likely than whites to have more than one emergency room visit in the last month of life in the VA cohort than in the Medicare cohort.

5.1.4   Effectiveness of Care in VA Compared with Non-VA

Most studies demonstrated better effectiveness of care (provision of recommended care) for VA compared with non-VA care, particularly for outpatient care. VA care outperformed non-VA care for non-Veterans on effectiveness of care measures for chronic conditions (Trivedi et al., 2011; Weeks et al., 2009b). Receipt of diabetes education (Nelson et al., 2005) was higher among VA patients compared with Veterans in non-VA care. VA patients were more likely than Veterans not receiving any care at VA to receive recommended care (Lynch, Strom, & Egede, 2010; Ross et al., 2008),[58] a routine checkup within the past two years (West et al., 2006), and influenza and pneumonia vaccinations (Chi, Reiber, & Neuzil, 2006; Jha, Wright, & Perlin, 2007; Keyhani et al., 2007)[59], but the two groups had similar rates of serum cholesterol screening

---

[58] Ross (2008) did not specify whether the non-VA comparison group was composed of non-Veterans, Veterans, or a combination of the two.

[59] Jha (2007) did not specify whether the non-VA comparison group was composed of non-Veterans, Veterans, or a combination of the two.

(Keyhani et al., 2007). Obese VA patients were more likely to have received advice to lose weight than Veterans and non-Veterans receiving non-VA care and equally likely to have received professional advice to maintain weight (Wang et al., 2005). Blood pressure control was higher among African-American patients receiving VA care than non-VA care (Rehman et al., 2005). The structure of women's health care differed at VA women's health centers and non-VA care sites: Preventive cancer screening and general reproductive services were available at all centers, while VA centers were less likely to offer extensive reproductive services on-site but more likely to offer on-site mental health care (Bean-Mayberry et al., 2007). Liu et al. (2008b) compared Veterans receiving primary care at VA-staffed versus contract community clinics and found that diabetic patients at VA-staffed clinics were less likely to receive a retinal exam and chronic obstructive pulmonary disease patients at VA-staffed clinics were less likely to receive a flu shot.

Elderly VA patients were less likely to receive inappropriate medication than were patients in Medicare HMOs (Barnett et al., 2006a), and VA patients with acute myocardial infarction were more likely to receive appropriate medications than were non-VA patients (Bansal et al., 2005). Observed compliance by providers with erythropoietin administration guidelines was higher at VA than in the private sector (Hynes et al., 2007). Antibiotic prescribing practices were generally similar between VA and non-VA emergency departments, but a few VA sites had much higher rates of antibiotic prescriptions (Gonzales et al., 2006).

In non-ambulatory settings, VA care was generally more effective than or the same as care provided by non-VA providers in most studies. Compared with non-VA patients from the Medicare cancer patient database, VA patients had earlier diagnosis of colon and rectal cancers, higher rates for three quality measures, similar rates for nine, and lower rates for one (Keating et al., 2011). Male VA patients and Medicare patients with lung and colorectal cancer were compared, and VA patients were less likely to receive chemotherapy within 14 days of death or to be admitted to an ICU within 30 days of death, and were similarly likely to have more than one emergency room visit within 30 days of death (Keating et al., 2010). Comparison of an academic practice and a VA hospital found that appropriate use of stress/rest myocardial perfusion imaging studies did not differ between settings (Nelson, Willens, & Hendel, 2011). Rates of hemodialysis via arteriovenous fistulas (which are preferred by guidelines over other methods) among VA patients and Medicare patients were not different when pre-end-stage renal disease care was accounted for (Parikh et al., 2011). Among Veterans who died in VA facilities, palliative care consults and death in a dedicated palliative care, hospice unit, or intensive care unit were more common, and death in a nursing home was less common than among Veterans who died in non-VA facilities (all unadjusted results) (Lu et al., 2010). VA-insured and Medicare/Medicaid-insured patients were less likely to receive kidney transplants than were patients with private insurance (Gill et al., 2007). Eight of 15 clinical pharmacy services were more commonly provided in VA hospitals than non-VA hospitals (Bond & Raehl, 2007).

Although not part of the systematic review because it was not published in the peer-reviewed literature, an Altarum/RAND study of VA quality of care for mental health conditions (Sorbero et al., 2010; Watkins et al., 2011) showed that VA care performed significantly better than the private plans on assessment measures and medication-management measures. The private

plans exhibited significantly higher rates of engagement for two measures related to treatment for substance use disorders.

5.1.5 Efficiency of Care in VA Compared with Non-VA

Studies of VA compared with non-VA care found VA to be less efficient. Nine articles compared utilization, all of which adjusted for differences in patient characteristics. Inpatient length of stay was generally longer in VA facilities, and the risk of hospitalizations and emergency visits was also generally higher. Mean length of stay among female Veterans was significantly longer for VA hospitals than private-sector hospitals even after adjustment for patient differences (Mooney & Weeks, 2007). Weeks et al. (2008a) identified Veteran stays in VA and non-VA hospitals and found longer length of stay for VA hospitalization even after adjusting for patient characteristics. Berke et al. (2009) found that Veterans admitted to VA hospitals had longer length of stay than expected after adjustment, compared with Veterans in non-VA hospitals.

In terms of other types of utilization, Wang et al. (2013b) found that Veteran patients who exclusively received dialysis at VA-outsourced settings were less likely than Veteran patients exclusively receiving VA dialysis to be hospitalized within a year, and had shorter length of stay than VA users. Hynes et al. (2011) compared VA hemodialysis patients with private-sector hemodialysis patients and found that VA patients had more non-dialysis outpatient visits, emergency room visits, 30-day supplies of prescriptions, inpatient admissions for acute medical or surgical care, and hospital days, but no difference in non-acute admissions and days of care. Liu et al. (2009) found that depressed Veterans who were dual VA/non-VA patients had a significantly higher chance of having an emergency visit and any inpatient admission than those exclusively receiving VA care. Liu et al. (2008) found that Veterans who received primary care at non-VA contract community clinics compared with Veterans at VA-staffed community clinics had fewer primary care and laboratory visits, but no significant differences in numbers of visits for specialty care, mental health care, radiology, or inpatient admission. Borzecki et al. (2010) found appendectomy utilization rates declined more rapidly, laparoscopic cholecystectomy rates rose more steeply, and bilateral catheterization rates decreased more slowly over time for VA patients compared with a national sample of hospitalized patients. (Gellad et al., 2013) found that VA patients used fewer brand-name drugs than Medicare patients, and that per capita volume of prescriptions filled was slightly lower among Medicare patients than VA patients.

As noted in the Methods Overview in Section 2, comparisons of costs in VA compared with non-VA settings are subject to a number of limitations; therefore, results related to cost of care are not presented.

5.1.6 Patient-Centeredness of Care in VA Compared with Non-VA

Based on studies published in the peer-reviewed literature, performance, on patient experience measures was comparable or better for patients receiving care at VA facilities compared with non-VA providers. Only five studies examined this dimension. Belote, Fulton, and Brooks (2012) found that Veteran patients rated outpatient care received at VA-staffed CBOCs more highly based on measures of continuity of care, education and information, emotional support, overall

coordination, and patient preferences compared with outpatient care provided at contractor-staffed CBOCs. Lu et al. (2010) observed that families of Veterans who died in a VA facility rated care and services during the patient's last month of life more highly than families of Veterans who died in non-VA settings. Another study (Cox, Alexander, & Gray, 2005) found greater satisfaction with hearing aid fittings and perceived benefit from hearing aid placement among Veterans in a VA facility than from non-Veteran patients. As noted in Section 4, Hausmann et al. (2009) concluded that perceptions of racial discrimination when seeking health care were similar between Veterans who were users of VA care and Veterans who were users of non-VA care, and McGuire, Rosenheck, and Kasprow (2010) found that homeless Veterans treated at VA-staffed transitional residential treatment programs had similar outcomes and patient satisfaction scores at 12 months compared with Veterans treated at two community-based programs.

Although not part of the systematic review because it was not published in the peer-reviewed literature, a report of results from the 2013 American Customer Satisfaction Index suggests that satisfaction with VA facilities is better than satisfaction with hospitals in the private sector, although results are not adjusted for patient characteristics that may differ between VA and non-VA facilities (American Customer Satisfaction Index, 2014).

5.1.7 Subsection Summary

The findings of previous studies comparing quality of care provided in VA settings compared with non-VA settings varied by quality domain. Studies of safety and effectiveness indicated mixed performance, with 22 of 34 studies of safety and 20 of 24 studies of effectiveness showing quality of care was the same or better in VA facilities. Only five articles assessed patient-centeredness but all demonstrated better or same VA care quality compared with care in non-VA settings. Four studies focused on equity, with one showing better performance, two same, and one worse performance compared with non-VA settings. The nine articles evaluating measures of efficiency such as hospital length of stay demonstrated more mixed or worse performance in VA facilities compared with non-VA facilities, with only two showing better performance. Only one study assessed timeliness of care in VA facilities, showing worse performance than the non-VA facilities.

5.2 VA Measurement of Quality of Care

As one of the largest health care providers in the United States, VA has assumed a national leadership role in the quality measurement arena. VA's efforts to measure the quality of care provided to Veterans began before those of many other health care organizations, and VA sets high standards for both measuring and improving quality (Jha et al., 2003; Kizer & Dudley, 2009).

VA currently uses multiple quality monitoring systems—tailored for different care settings and audiences—to collect and report information about the health of Veterans and the care provided to them. Among these systems is ASPIRE, which is considered by the Institute of Medicine to be one of several sentinel quality measurement initiatives that "identified a limited set of measures from a larger pool" (Institute of Medicine, 2015). ASPIRE is part of the VA

Transparency Program, which offers publicly available information on the VA Hospital Compare website about how VA is performing relative to other health care organizations across the country. ASPIRE presents information about all aspects of quality, including preventive care, care recommended for acute and chronic conditions, complications and outcomes of care, and patient-reported measures of health care experiences at the national, regional, and local levels of the VA system. VA's ASPIRE is working to develop a quality measurement and reporting model that is more streamlined and focused on what VA considers to be the most important aspects of quality.

In addition to the measures provided by ASPIRE, VA has more than 500 other quality measures that can be used by VISN and facility administrators and providers to monitor quality of care regionally and locally and to inform quality improvement projects. In addition, the VA Office of Mental Health Operations has developed more than 240 measures focused on conditions related to mental health, including post-traumatic stress disorder and depression. These measures are part of an extensive infrastructure within VA for performing quality improvement and research on quality of care. VA offers unique research opportunities, with clinical data available on 6 million enrollees through its electronic health record system, CPRS/VistA (Fihn et al., 2014), including developing and testing new quality measures and examining the relationship between evidence-based care and clinical outcomes.

By all accounts, VA has an extensive set of measures for most conditions and purposes. Across the U.S. health care system, quality reporting requirements have expanded and measurement has become more complicated, resulting in a huge commitment of staff time and funds to comply (Institute of Medicine, 2015). Some have argued that a proliferation of performance measures within VA has led to a lack of focus on what is truly important (Kizer & Jha, 2014).

In interviews, VA administrators and several health care workers noted that attention to quality measurement has led to positive changes in care delivery, particularly by directing attention to conditions for which there are quality measures. For example, one facility uses quality measurement data to identify high-risk patients for more-intensive case management. Another facility initiated patient education in response to high readmission rates and was successful at lowering readmissions. Furthermore, attention to measuring access and quality also appeared to improve coding and documentation. However, several respondents interviewed felt that measuring quality did not always have a positive effect on how facilities deliver care. For example, one respondent said that everyone is "so focused on the numbers that we lose sight sometimes of the process that we're trying to deliver." Others explained that the current list of access and quality measures is "just too long" and the measurement process is a burden for VA providers and other staff members. In addition, one respondent reported that some individual program offices generate their own sets of measures independently, ultimately adding to the already large number of measures.

In the subsections below, we report how VA has performed on commonly used, accepted measures developed by leading health care organizations. We analyzed quality measures for VA care and compared them to the same quality measures for comparable non-VA providers. The measures are described in Subsection 2.6.3, Methods Overview. The measures are a subset of publicly reported VA quality measures, selected because of the availability of non-VA

comparisons. We describe the non-VA comparisons used below in the discussion of each subset of quality measures.

5.2.1 VA Performance on Quality Measures Compared with Non-VA

Our analysis of quality measure performance indicated that, on most publicly reported measures, on average, the quality of VA outpatient care was better than the quality of non-VA outpatient care, and, on average, the quality of VA inpatient care was the same as or better than the quality of non-VA inpatient care. Some measures of patient experience and three measures of readmission indicated lower quality, on average, at VA hospitals than non-VA hospitals. These findings are based on our analysis of quality of care for many types of care provided in the inpatient and outpatient settings.

We analyzed a total of six quality measures on inpatient safety, six on inpatient safety outcomes, 30 on effectiveness (14 inpatient and 16 outpatient), and 11 on patient-centeredness for the inpatient setting. Measures of efficiency, equity, and timeliness were not analyzed because similar measures were not available for non-VA providers. For each quality measure, we conducted descriptive analyses of the performance rates available at the facility level, noting the variation in performance across facilities nationwide. We summarized the distribution of each measure using the mean, minimum, and maximum. The performance rates for the quality measures reported in Section 5 and in the Appendix G tables were each calculated as an unweighted mean of the facility-level means.[60] We classified the results of the analysis according to statistically significant differences in quality of care measures for VA care relative to the non-VA comparison group. We used the same dimensions of quality to classify the results that we used in the systematic review (see introduction to Subsection 5.1).

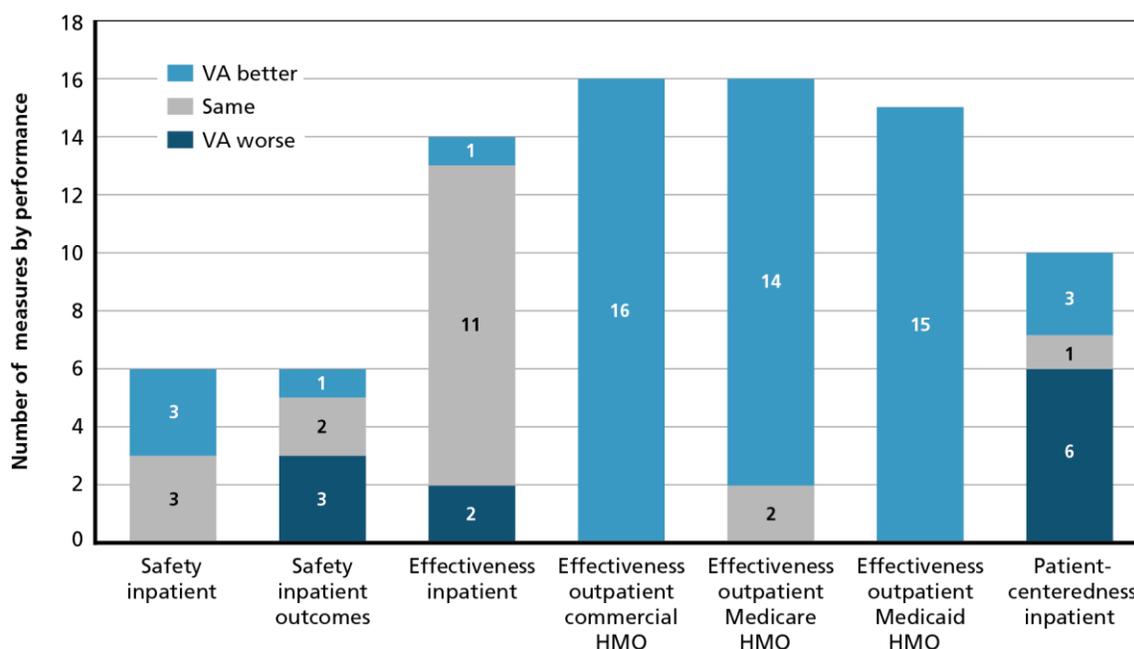
The average performance of VA facilities was the same or significantly better than the average performance of non-VA care on the majority of quality measures analyzed for inpatient and outpatient settings (Figure 5-2). On average, VA hospitals performed the same as or significantly better than non-VA hospitals on 12 inpatient effectiveness measures, all six measures of inpatient safety, and all three inpatient mortality measures, but significantly worse than non-VA hospitals on two effectiveness measures and three readmission measures. VA performed significantly better, on average, on all 16 outpatient measures of effectiveness compared with commercial HMOs, on 14 of 16 outpatient effectiveness measures compared with Medicare HMOs, and on all 15 outpatient measures of effectiveness compared with Medicaid HMOs. Veteran-reported experiences of care in VA hospitals were worse than patient-reported experiences in non-VA hospitals on most measures. Average VA facility-level performance was significantly worse than non-VA facilities for six out of 10 patient experience measures, including communication with nurses and doctors. Although these results indicate

---

[60] The value of mean measure rates calculated for this report may differ slightly from means reported in VA publications for the same time period, due to differences in methods used to calculate the means. For this report, we calculated an unweighted mean of facility-level means, whereas VA calculates a national mean value for each performance measure based on patient-level data.

---

strong performance by VA facilities, considerable variability across facilities was observed in all quality measures, indicating substantial room for improvement in the performance on quality measures and inpatient experience measures for many VA facilities. In the following subsections, more information is provided about the analyses underlying these findings.

Figure 5-2. VA versus Non-VA Quality of Care, by Type of Quality Measure


Source: RAND summary of results of VA to non-VA comparisons. Data sources for analyses conducted by RAND are provided in figure notes throughout this section.
Notes: Categories are defined on the basis of statistical tests for difference in means with *P*<0.05 or less: VA better = VA quality of care shown to be better than non-VA; same = quality of care in VA and non-VA did not differ; VA worse = VA quality of care was shown to be worse than non-VA. Non-VA comparison data were not available for outpatient measures of patient-centeredness.

5.2.1.1 VA Compared with Non-VA Performance on Patient Safety Measures for Inpatient Setting

For inpatient quality measures, we compared performance rates for VA hospitals and non-VA hospitals. To ensure optimum comparability between VA and non-VA facilities in our analysis, we matched three non-VA facilities to each VA facility based on four facility characteristics: bed size, Census division, urban/rural location, and teaching hospital status.[61] We present measure

---

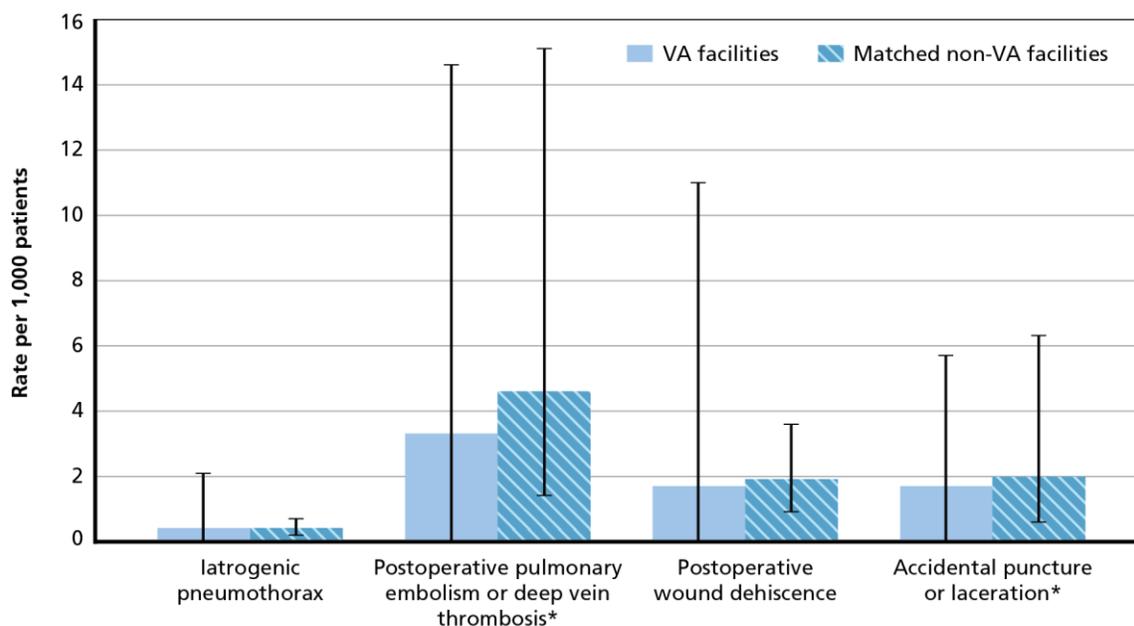
[61] A description of how we identified a matched set of non-VA comparator hospitals is provided in Section 2. Teaching facilities are defined to include all major and minor teaching hospitals, with a major teaching hospital

rates for VA and non-VA facilities side-by-side with a line indicating the minimum and maximum measure rate for each subgroup. In this subsection, results are presented for comparisons of VA facilities and matched non-VA hospitals for patient safety indicators. We used data on a standard set of AHRQ measures to assess how often adverse outcomes of care occur in the inpatient hospital setting. This included data on patient safety indicators obtained from the VA Inpatient Evaluation Center (VA facilities) and CMS Hospital Compare (non-VA facilities) and data on risk-standardized readmission and mortality rates obtained from CMS Hospital Compare (all facilities). For this set of measures, a lower rate indicates better performance. The number of VA and non-VA hospitals in the figures varies from measure to measure, due to the reporting criteria used by CMS Hospital Compare (see Appendix A for more detail).

The patient safety measures (Figure 5-3) are rates of complications or adverse events per 1,000 patients undergoing specific treatment or procedures. These complications occur infrequently, with the mean facility-level rates ranging from a minimum of 0.4 per 1,000 in both VA facilities and matched non-VA facilities for iatrogenic pneumothorax, to a maximum of 3.3 per 1,000 in VA facilities, and 4.6 per 1,000 in matched non-VA facilities for postoperative pulmonary embolism or deep vein thrombosis. Three measures were significantly lower (that is, performance was better) in VA facilities than in matched non-VA facilities: death following surgical complications (data not shown in Figure 5-3), postoperative pulmonary embolism or deep vein thrombosis rate, and accidental puncture or laceration rate. A substantial number of VA facilities reported no adverse events on these measures. For example, 12 of 101 hospitals reported no deaths among surgical inpatients with serious treatable complications, and 60 of 113 hospitals reported no patients with postoperative wound dehiscence (per 1,000). One patient safety measure not shown in Figure 5-3 is a composite measure that combines information from 11 patient safety indicator measures. The mean performance of this measure by facility for VA and non-VA inpatient care in FY 2014 was 0.9, indicating the rates of patient safety outcomes observed in these two subgroups of hospitals were less than expected, which is based on the rates for all hospitals in Hospital Compare (Figure 5-3). Rates varied widely across VA and non-VA facilities, as indicated by the lines extending from each bar representing the minimum and maximum values for each measure rate. Rates of postoperative pulmonary embolism or deep vein thrombosis exhibited the widest range for the 111 VA facilities (mean of 3.3 per 1,000, ranging from 0 to 14.6) and non-VA facilities (mean of 4.6 per 1,000, ranging from 1.4 to 15.1).

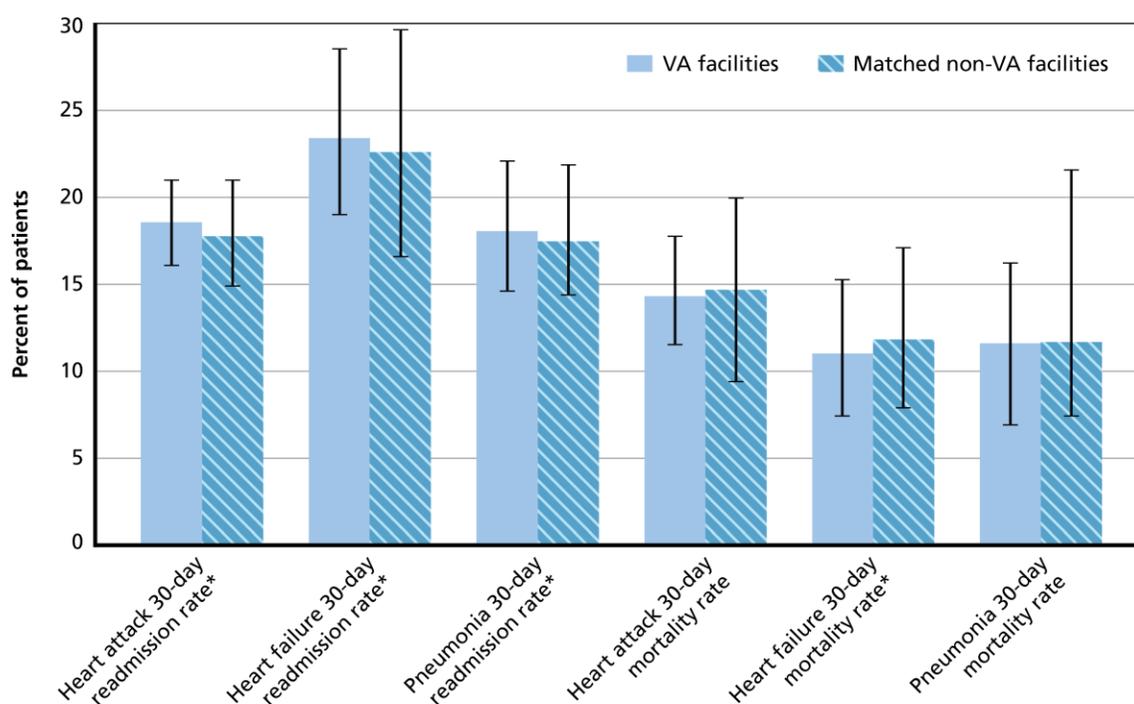
---

having a Council of Teaching Hospitals designation and a minor teaching hospital having another teaching hospital designation. Facilities without a teaching hospital designation are classified as non-teaching facilities.

Figure 5-3. VA and Non-VA Performance on Patient Safety Indicator Measures for Inpatient Setting, FY 2014


Sources: VA facility-level data for patient safety indicators were obtained from the VA Inpatient Evaluation Center for 2014. Non-VA facility-level data for patient safety indicator measures for Quarter 4 of FY 2014 were obtained from the CMS Hospital Compare website.
Notes: Minimum and maximum values for the reporting facilities in each subgroup are represented by the line extending from each bar. An asterisk (*) next to the measure name indicates a statistically significant difference between VA and non-VA performance. A lower rate on these measures indicates better performance. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

We compared mortality and readmission rates for VA facilities and matched non-VA facilities that are reported on the CMS Hospital Compare website (CMS, 2015) (Figure 5-4). The all-cause risk-standardized readmission and mortality rates for heart attack, heart failure, and pneumonia are adjusted for demographic characteristics and other medical conditions. The average all-cause risk-standardized rates of readmission within 30 days of discharge following heart attack, heart failure, and pneumonia were significantly higher (that is, significantly worse) than those in matched non-VA facilities (18.6, 23.4, and 18.1 per 1,000 in VA facilities versus 17.8, 22.6, and 17.5 per 1,000 in non-VA facilities, respectively). The facility-level mean all-cause risk-standardized mortality rate for heart failure within 30 days of admission was significantly lower (that is, significantly better) for VA facilities than for matched non-VA facilities. These all-cause risk-standardized rates varied widely for VA facilities, ranging from 15 to 29 percent for 30-day readmission rates and from 7 to 18 percent for 30-day mortality rates (Figure 5-4). Variability across the non-VA facilities was even higher.

Figure 5-4. VA and Non-VA Performance on Readmission and Mortality Measures for Inpatient Setting, FY 2014


Source: VA and non-VA facility-level data for readmission and mortality measures for Quarter 4 of FY 2014 that were obtained from the CMS Hospital Compare website.

Notes: Minimum and maximum values for the reporting facilities in each subgroup are represented by the line extending from each bar. An asterisk (*) next to the measure name indicates a statistically significant difference between VA and non-VA performance. A lower rate on these measures indicates better performance. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

5.2.2 Current VA Performance on Effectiveness Measures

5.2.2.1 VA Performance on Effectiveness Measures for Inpatient Setting

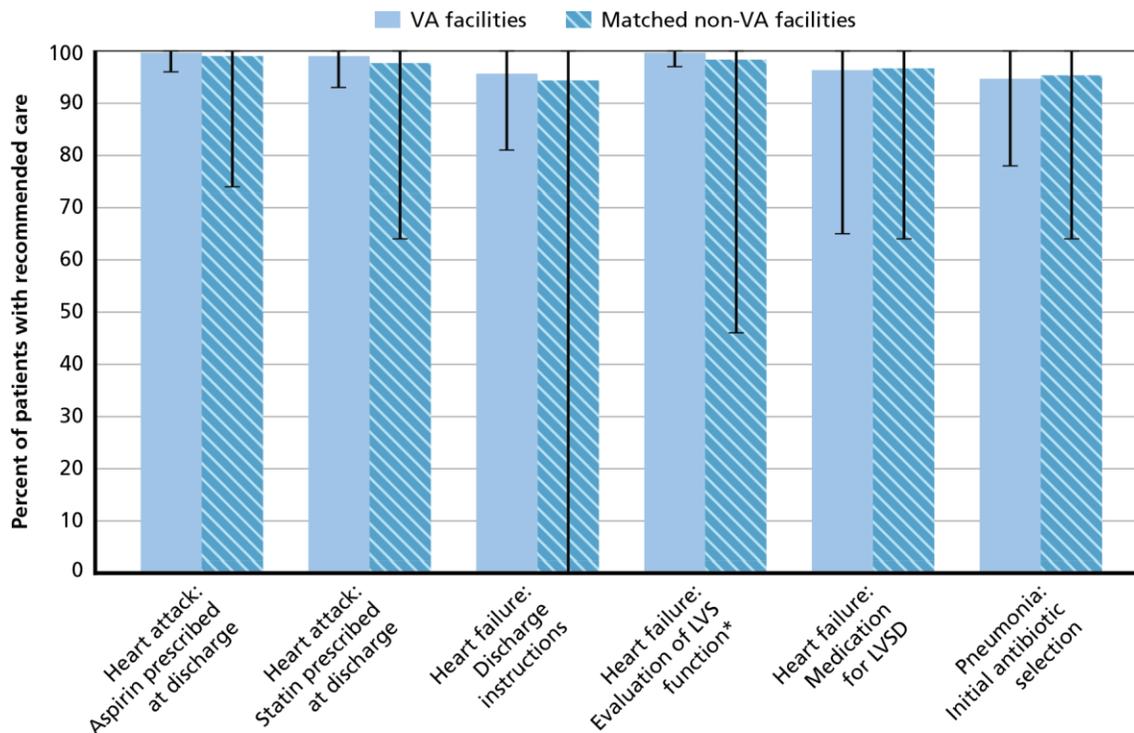
The ORYX process measures and Surgical Care Improvement Project measures assess how often recommended care is provided in the inpatient hospital setting of VA and non-VA facilities. These measures are used by the Joint Commission for hospital quality improvement and in their hospital accreditation process (The Joint Commission, 2015). The measures included in this report relate to heart attack, heart failure, pneumonia, and surgical care. The ORYX measure data were obtained from CMS Hospital Compare website (CMS, 2015). Individual measures

were reported to CMS Hospital Compare by different numbers of VA hospitals, ranging from eight to 118. Measures with data for fewer than 10 VA hospitals in FY 2014 were excluded from the analysis.[62]

For the six ORYX process measures for heart attack, heart failure, and pneumonia (Figure 5-5), inpatient care recommended by clinical practice guidelines was provided 95 percent of the time or more, on average, by VA and matched non-VA facilities. For five of six measures, VA and non-VA mean facility rates did not differ, but the rate of evaluation of left ventricular systolic function was significantly better in VA facilities. Many VA and non-VA facilities achieved a perfect score of 100 percent on these measures for providing appropriate care to hospitalized patients. Three of six of these measures had a wide range of values across VA facilities, from a 19- to 35-percentage-point difference between the lowest and highest facility, and for the other three measures a difference of 3 to 7 percentage points (see data in Appendix G for details). The measure rates for the matched non-VA facilities ranged even more widely with all six measures having at least a 26-percentage-point difference between the high and low value (Figure 5-5).

---

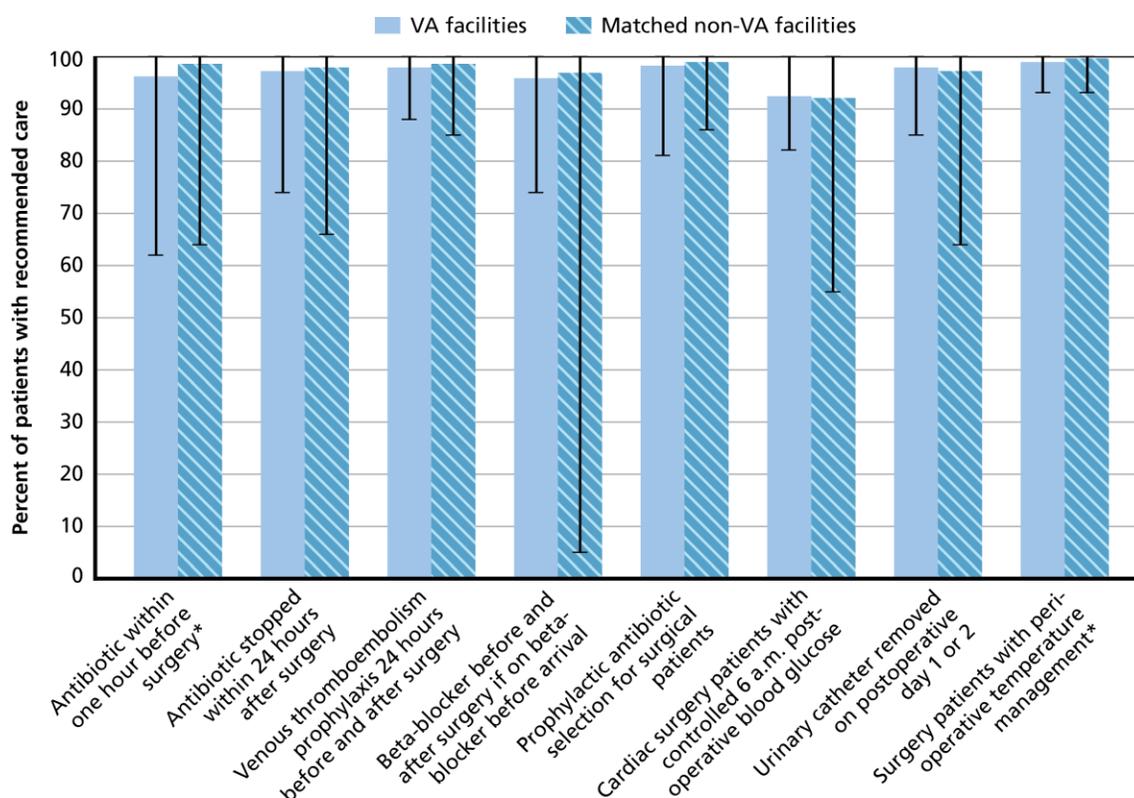
[62] For one effectiveness measure for the inpatient setting, timing of receipt of primary percutaneous coronary intervention, VA facilities had a significantly lower (worse) rate. However, we did not include this in Figure 5-5 because we excluded results based on fewer than 10 VA facilities.

Figure 5-5. VA and Non-VA Performance on ORYX Process Measures for Inpatient Setting, FY 2014


Source: VA and non-VA facility-level data for ORYX process measures for Quarter 4 of FY 2014 that were obtained from the CMS Hospital Compare website.

Notes: Minimum and maximum values for the reporting facilities in each subgroup are represented by the line extending from each bar. An asterisk (*) next to the measure name indicates a statistically significant difference. LVS = left ventricular systolic. LVSD = left ventricular systolic dysfunction. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

For the eight surgical care measures (Figure 5-6), recommended care was provided, on average, from 93 to 99 percent of the time by VA facilities and from 92 to 100 percent of the time in matched non-VA facilities. For two of eight measures (antibiotic within one hour before surgery, and surgery patients with perioperative temperature management), VA had significantly lower (worse) rates, and the other six rates did not differ. As with the ORYX measures, performance on these measures varied widely across VA facilities, with minimum rates of 62 to 93 percent and a maximum for all of these measures of 100 percent (see data in Appendix G for details). The range of values for the matched non-VA facilities was wider for all but one measure (Figure 5-6).

Figure 5-6. VA and Non-VA Performance on Surgical Care Improvement Project Measures for Inpatient Setting, FY 2014


Source: VA and non-VA facility-level data for Surgical Care Improvement Project measures for Quarter 4 of FY 2014 obtained from the CMS Hospital Compare website.

Notes: Minimum and maximum values for the reporting facilities in each subgroup are represented by the line extending from each bar. An asterisk (*) next to the measure name indicates a statistically significant difference. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

5.2.2.2   VA Performance on Effectiveness Measures for Outpatient Setting

We analyzed the quality of care for outpatient settings in VA facilities to observe variation across VA and non-VA facilities and to compare to performance in non-Veteran populations. We used a set of standard HEDIS outpatient measures to show how often evidence-based health care practices are followed and clinical outcomes of care occur. HEDIS measures are employed by many health care organizations in the United States to monitor performance on important aspects of health care as well as provider and plan service in the outpatient setting. HEDIS measures included in this report relate to screening, prevention, and wellness; and

management of chronic medical conditions, such as diabetes, hypertension, cardiovascular disease, and depression. The target rate for HEDIS measures is 100 percent.[63]

Based on the latest available rates (FY 2014) from VA facilities, we estimated the mean performance and how much VA performance varies by facility (Table G-1 in Appendix G). These measures are constructed so as not to require adjustment for patient risk or other characteristics. For measures related to screening, prevention, and wellness, the mean percentage of users of care at VA facilities who received recommended services ranged from 58 percent (influenza immunization 18–64 years) to 95 percent (advising smokers and tobacco users to quit) (Table G-1 in Appendix G). Under measures related to chronic condition management, 90 to 99 percent of patients with diabetes and cardiovascular disease received recommended care (Table G-1 in Appendix G). Measurement of the extent to which risk factors are controlled in VA patients indicated 67 percent (low density lipoprotein-cholesterol, or LDL-C), 78 percent (blood pressure), and 81 percent (HbA1c)[64] of those with diabetes, 75 percent (blood pressure) of those with hypertension, and 70 percent (LDL-C) of those with cardiovascular disease have achieved clinical targets (Table G-1 in Appendix G). The variation in performance across VA facilities differed dramatically by measure, with the difference between the highest- and lowest-performing VA facilities ranging from 5 percent (hemoglobin A1c test for diabetes) to 38 percent (use of antidepressants during the continuation phase for patients with newly diagnosed depression) (Table G-1 in Appendix G).

We also report performance on outpatient measures of the quality of care for VA compared with three external benchmarks from the National Committee for Quality Assurance: commercial HMOs, Medicare HMOs, and Medicaid HMOs. We present these because VA has used them as comparison groups in VA annual reports (VA, 2013d). However, the characteristics of patients in these populations may differ from Veterans' characteristics in important ways. In addition, the data sources and methodology used to collect the data differ between VA and National Committee for Quality Assurance for some measures (see notes on Figures 5-7, 5-8, and 5-9). For this analysis, we used FY 2013 data for VA patients to align with the latest available data for the non-VA comparison groups (calendar year 2013).

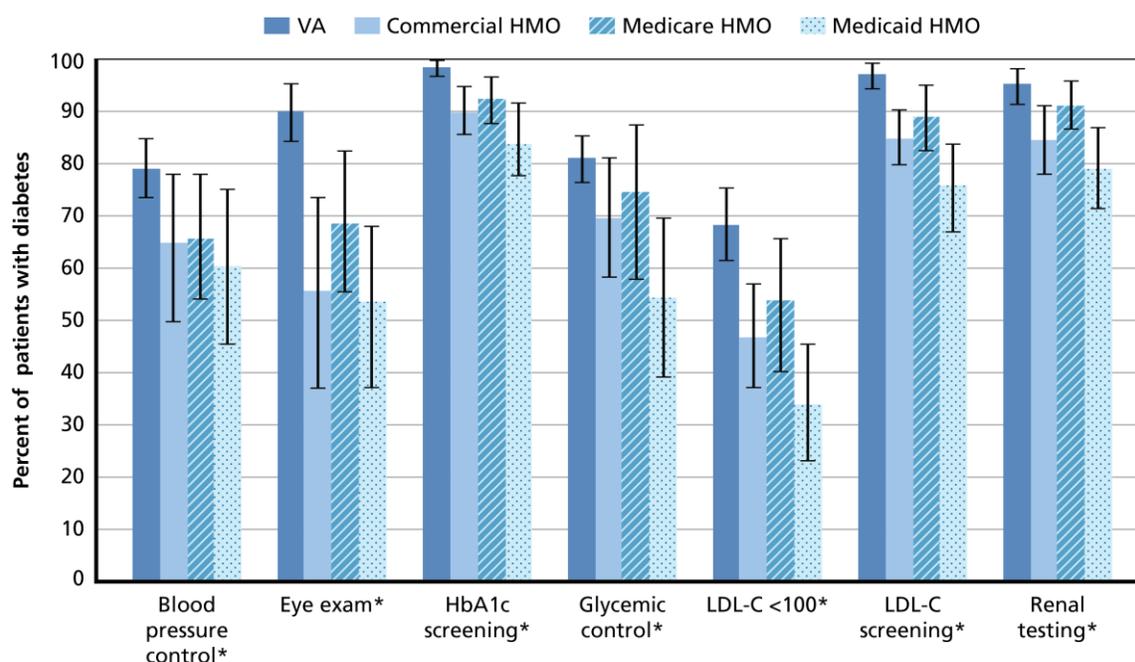
We found that VA patients with diabetes were significantly more likely to receive recommended care or achieve clinical targets in the outpatient setting from VA providers than patients in commercial HMOs, Medicare HMOs, and Medicaid HMOs (Figure 5-7). VA performance on the seven measures of diabetes care in Figure 5-7 exceeded the non-VA comparison groups by a wide margin. There is substantial variability in performance across VA facilities for some of the measures, based on difference of 3 to 14 percentage points between the 10th and 90th percentiles (see lines on the bars in Figure 5-7). However, the commercial

---

[63] For a few HEDIS measures, a lower rate indicates better performance. For these, the target rate is 0 percent rather than 100 percent.

[64] The HEDIS measure in Table G-1 is reported as "poor control." Here we convert it to adequate control as (100-N) where N is the measure rate in Table G-1.

HMOs, Medicare HMOs, and Medicaid HMOs all exhibited much more variability than VA facilities.

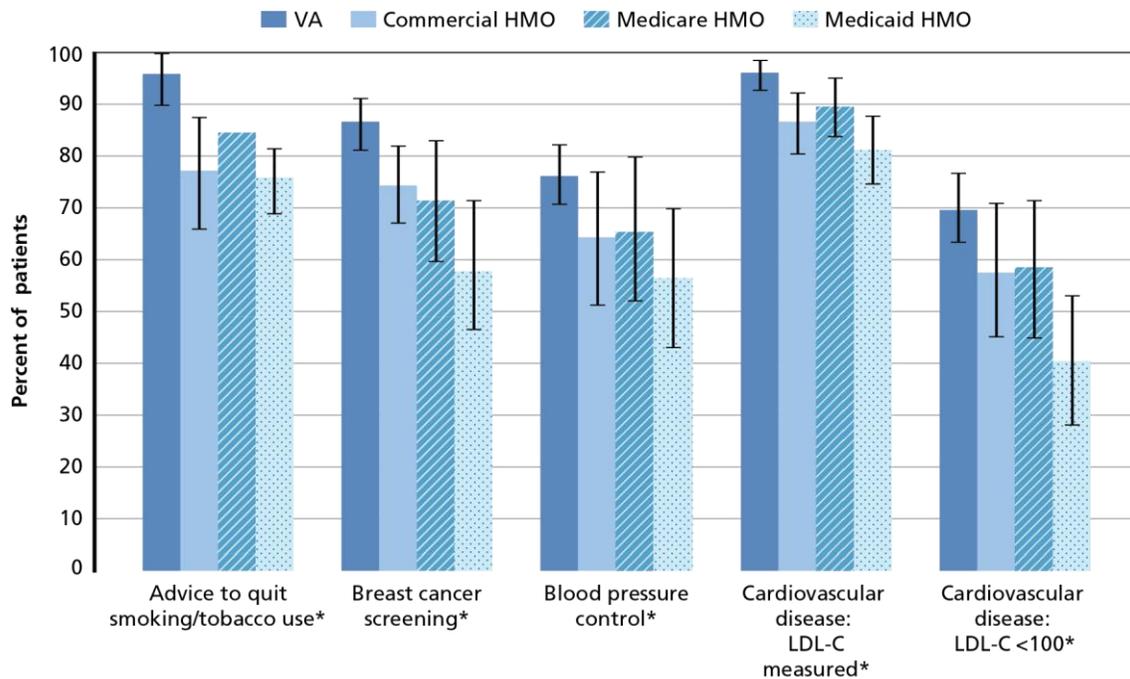
Figure 5-7. Performance on Outpatient Measures of Diabetes Care Quality, VA FY 2013 Compared with Non-VA CY 2013


Notes: The 10th and 90th percentiles for the reporting facilities in each subgroup are represented by the line extending from each bar. An asterisk (*) next to the measure name indicates a statistically significant difference between VA and one or more of the non-VA comparison groups. HbA1c = hemoglobin A1c. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

Sources: Facility-level data for VA patients for FY 2013 were obtained from the VA Office of Performance Measurement. National means, and 10th and 90th percentiles for CY 2013 for non-VA subgroups of patients (commercial HMO, Medicare HMO, and Medicaid HMO) were obtained from the following report: National Committee for Quality Assurance. 2014. *The State of Health Care Quality 2014.* Available March 20, 2015, at www.ncqa.org. VA data were collected by abstracting medical record data similar to HEDIS methodology. VA data were based on a fiscal year. Non-VA data were based on a calendar year.

Similarly, VA patients were significantly more likely than patients in commercial HMOs, Medicare HMOs, and Medicaid HMOs to have preventive care (advice about smoking cessation and breast cancer screening) or controlled risk factors (blood pressure control for hypertension, and LDL-C less than 100 mg/dL for cardiovascular disease) in the outpatient setting (Figure 5-8). VA performance on the five measures in Figure 5-8 was closer to the non-VA comparison groups than the diabetes measures in Figure 5-7, but still significantly higher. There is

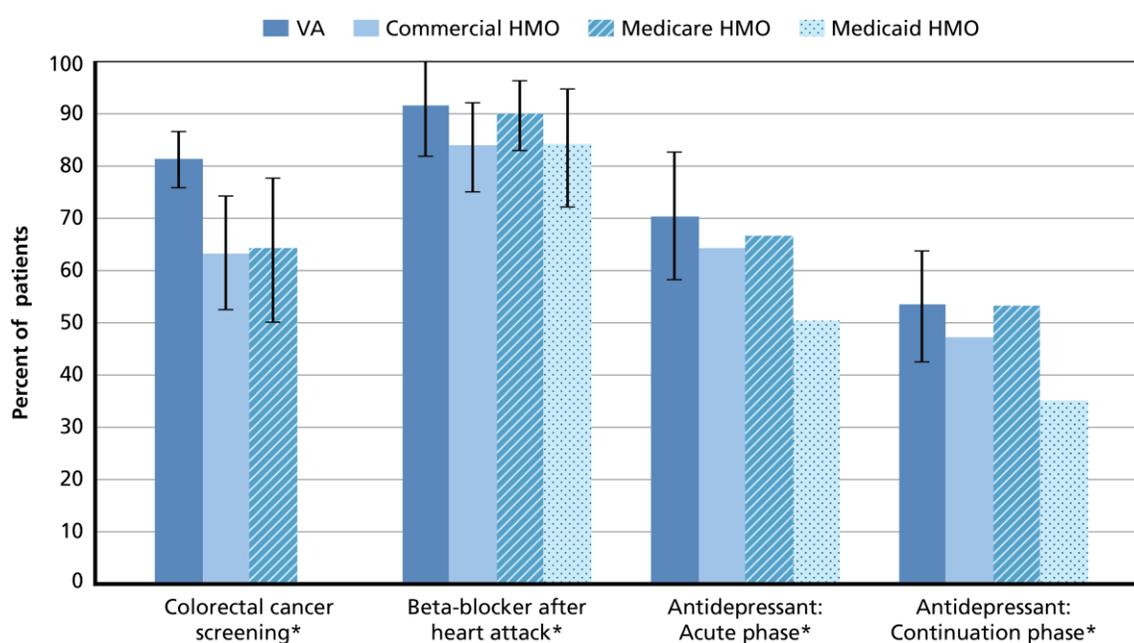
substantial variability in performance across VA facilities for these measures, based on differences of 6 to 13 percentage points between the 10th and 90th percentiles (shown on the bars in Figure 5-8). The commercial HMOs, Medicare HMOs, and Medicaid HMOs all exhibited considerably more variability than VA facilities.

Figure 5-8. Performance on Other Outpatient Quality Measures, VA FY 2013 Compared with Non-VA CY 2013


Notes: The 10th and 90th percentiles for the reporting facilities in each subgroup are represented by the line extending from each bar. These percentiles are not available for Medicare HMOs for "Advice to Quit Smoking/Tobacco Use." An asterisk (*) next to the measure name indicates a statistically significant difference between VA and one or more of the non-VA comparison groups. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.
Sources: Facility-level data for VA patients for FY 2013 were obtained from the VA Office of Performance Measurement. National means, and 10th and 90th percentiles for CY 2013 for non-VA subgroups of patients (commercial HMO, Medicare HMO, and Medicaid HMO) were obtained from the following report: National Committee for Quality Assurance. 2014. *The State of Health Care Quality 2014.* Available as of March 20, 2015, at www.ncqa.org. VA data for all measures were collected by abstracting medical record data. HEDIS data were collected by medical record abstraction for all measures except "Advice to Quit Smoking/Tobacco Use" which is survey data. VA data were based on a fiscal year. Non-VA data were based on a calendar year.

Another four outpatient measures are compared between VA patients and commercial HMOs, Medicare HMOs, and Medicaid HMOs in Figure 5-9. These focus on preventive care (colorectal

cancer screening) and medication use (beta-blocker after heart attack and antidepressants for depression). VA performance on the four measures in Figure 5-9 exceeded most of the non-VA comparison groups, but the differences were smaller. Differences between VA and Medicare HMO rates were not significant for two measures (beta-blocker after heart attack and antidepressants during continuation phase). There is much more variation in performance across VA facilities for these measures, based on difference of 11 to 24 percentage points between the 10th and 90th percentiles (shown by lines on the bars in Figure 5-9). For the two measures with non-VA variability estimates, commercial HMOs, Medicare HMOs, and Medicaid HMOs all exhibited somewhat more variability than VA facilities.

Figure 5-9. Performance on Other Outpatient Quality Measures, VA FY 2013 Compared with Non-VA CY 2013


Notes: The 10th and 90th percentiles for the reporting facilities in each subgroup are represented by the line extending from each bar; these are not available for the non-VA comparison groups for the two antidepressant measures. An asterisk (*) next to the measure name indicates a statistically significant difference between VA and one or more of the non-VA comparison groups. The Colorectal Cancer Screening rate for Medicaid HMOs is not available. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

Sources: Facility-level data for VA patients for FY 2013 were obtained from the VA Office of Performance Measurement. National means, and 10th and 90th percentiles for CY 2013 for non-VA subgroups of patients (commercial HMO, Medicare HMO, and Medicaid HMO) were obtained from the following report: National Committee for Quality Assurance, 2014. *The State of Health Care Quality 2014.* Available as of March 20, 2015 at www.ncqa.org. VA data for the Colorectal Cancer Screening and Beta-Blocker after Heart Attack measures were collected by

abstracting medical record data. VA data for the Antidepressant Medication Management (Acute Phase and Continuation Phase) measures and all of the HEDIS measures were based on administrative data. VA data were based on a fiscal year. Non-VA data were based on a calendar year.

5.2.3   Current VA Performance on Patient-Centeredness Measures

5.2.3.1   VA Performance on Patient-Centeredness Measures for Inpatient Setting

To assess their experience with inpatient services provided by VA, patients in VA and non-VA facilities are asked to report on their experiences of care on the Inpatient SHEP. This survey parallels the HCAHPS Survey administered by non-VA hospitals across the country. For matched non-VA hospitals, we used HCAHPS data that were reported on the CMS Hospital Compare website (CMS, 2015). Figure 5-10 presents the average percentage of patients who responded "always" to individual questions or to sets of questions (composites) that measure related concepts. To allow for fair comparisons between VA and non-VA facilities, results for both VA and non-VA facilities are adjusted for patient characteristics, mode of survey administration, and national mean hospital performance using guidance provided by CMS.

The facility-level mean of patient experience scores ranged from a low of 51 and 43 percent for care transition for, respectively, VA and matched non-VA facilities, to a high of 84 and 86 percent for discharge information, respectively, for VA and matched non-VA facilities (Figure 5-10). Observed differences between VA and non-VA facility performance were statistically significant for all inpatient patient experience measures except discharge information. We classified the magnitude of the difference as small, medium, or large, using a Cohen's d statistic. Compared with non-VA facilities, VA facilities performed better by a large amount for the measure of care transition, and better by a small amount with regard to communication about medicine and the cleanliness of the hospital (Figure 5-10). VA facilities performed worse than non-VA facilities by a small amount for measures responsiveness of hospital staff, quietness of the hospital environment, and overall rating of the hospital (data not shown).[65] VA facilities performed worse than non-VA facilities by a medium amount for the measures of communication with doctors and communication with nurses, and by a large amount for pain management.

Variation in inpatient patient experience measures across VA facilities was very high, with a 17- to 42-percentage-point difference between the lowest and highest ratings by facility (Figure 5-10).[66] Even more variation in measure rates was observed for the matched non-VA facilities. As

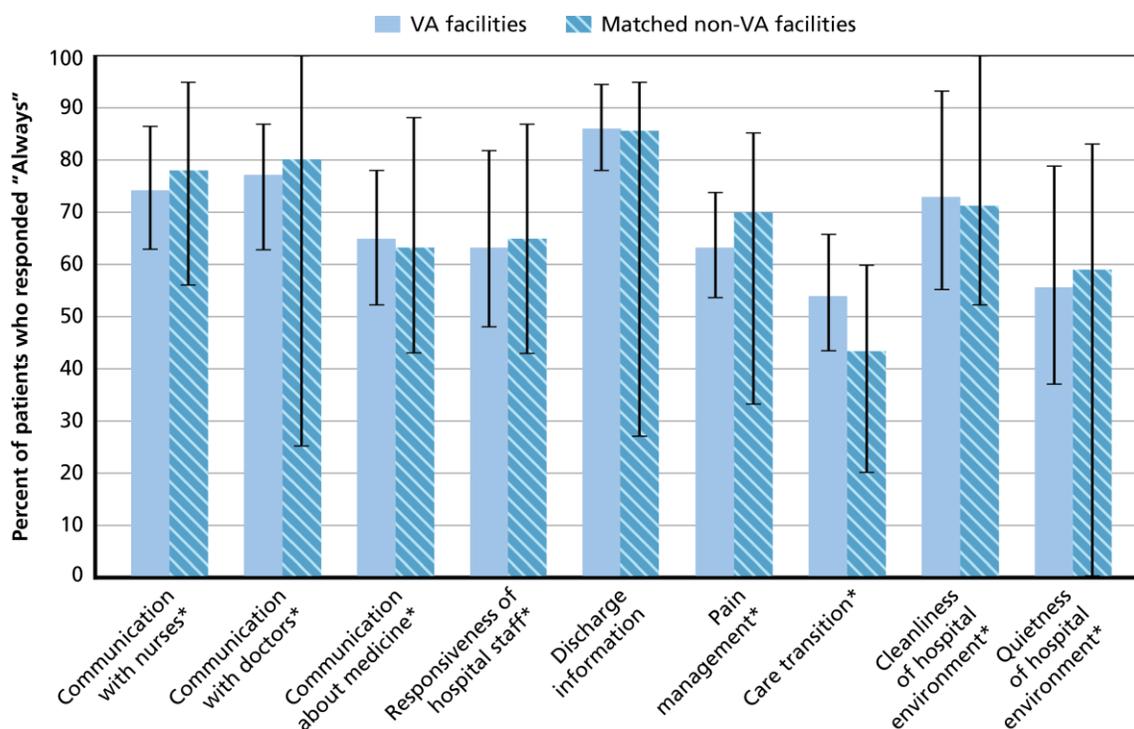
---

[65] We did not compare VA to non-VA facility performance on the "Willingness to Recommend Hospital" measure, as the likelihood of Veterans' recommending a VA facility to friends and family members may be affected by their eligibility for care at VA facilities.

[66] To assess variation in inpatient SHEP scores across facilities within VA, we used inpatient SHEP scores that VA adjusted using its internal patient mix adjustment model, which includes the following variables: age, sex, priority group, urban/rural residence, hospital service line (surgical/medical), self-reported health status, self-reported mental health status, education, and race/ethnicity.

---

described in Section 4, differences of as few as three to six percentage points on questions on a CAHPS health plan survey have been associated with substantial differences in rates of voluntary disenrollment from Medicare plans (Lied et al., 2003), suggesting that the large variation in inpatient SHEP scores across VA facilities is reflective of large and meaningful differences in patients' experiences of care at these facilities.

Figure 5-10. VA and Non-VA Performance on Patient Experience Measures for Inpatient Setting, FY 2014


Sources: VA facility-level data for patient experience measures for FY 2014 were obtained from the VA Office of Performance Measurement. Non-VA facility-level data for patient experience measures for Quarter 4 of FY 2014 were obtained from the CMS Hospital Compare website. Notes: Minimum and maximum values for the reporting facilities in each subgroup are represented by the line extending from each bar. An asterisk (*) next to the measure name indicates a statistically significant difference at $p < 0.05$ or less between VA and non-VA hospitals. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

5.2.3.2 VA Performance on Patient-Centeredness Measures for Outpatient Setting

To assess patient experience with outpatient services provided by VA, a sample of patients receiving VA outpatient care at each VA facility is asked to report on their experience with their health care provider over the past 12 months on the SHEP PCMH. Figure 5-11 presents the VA facility average percentage of patients who responded "always" to individual questions or to sets of questions (composites) that measure related concepts. Results are adjusted for patient

characteristics to allow for fair comparisons across VA facilities.[67] The mean reports of Veterans' experiences ranged from a low of 56 percent for self-management support to a high of 84 percent for talking about prescription medicines at each visit. Variation across facilities was very high, with more than a 20-percentage-point difference between the lowest and highest ratings by facility for most measures, and a 40-percentage-point difference for the measure on follow-up on test results.

As noted in Section 4, there are no nationally representative data with which to compare SHEP PCMH results.[68] However, the SHEP PCMH contains the same measures as the CAHPS Clinician & Group PCMH Survey that is used widely throughout the United States to collect information on patients' experiences with care. The CAHPS Database hosted by the AHRQ contains comparative data for this survey from medical practices that volunteer to submit their survey responses. The most recent year of the Database available at the time of this report, 2013, includes results from 833 participating practice sites administering the CAHPS Clinician & Group PCMH Survey (Agency for Healthcare Research and Quality (AHRQ), 2015). These practices do not constitute a representative sample of all medical practices in the United States, and, given practices' willingness to voluntarily submit their scores, high-performing practices are likely over-represented. The practices differ from the complete set of VA facilities for which we report performance. Therefore, we compare the performance of the *top-performing VA facilities* in FY 2014 with the *average performance of the Database practices* in 2013 to examine the relative strengths and weakness of top-performing VA and non-VA facilities. Since some CAHPS Database practices may not be high performers, we also compare the performance of the *75th percentile of VA facilities* for each measure with the *average performance of the Database practices*.

We were not able to adjust the Database survey scores to account for factors such as respondents' age, sex, self-reported health and mental status, or education, which have been shown to be associated with reporting systematically higher or lower responses on patient experience surveys (Zaslavsky et al., 2001; Hargraves et al., 2001; Elliott et al., 2009). Our analyses of inpatient SHEP data, described above, suggest that adjusting for these factors may account for differences of up to three percentage points in either direction between reports of patient experience from SHEP and those from a comparable CAHPS survey, and an average of four points for overall ratings of care.[69] Thus, if differences between VA SHEP top-performing

---

[67] VA's internal patient mix adjustment model for the outpatient SHEP includes the following variables: age, sex, priority group, urban/rural residence, self-reported health status, self-reported mental health status, education, and race/ethnicity.

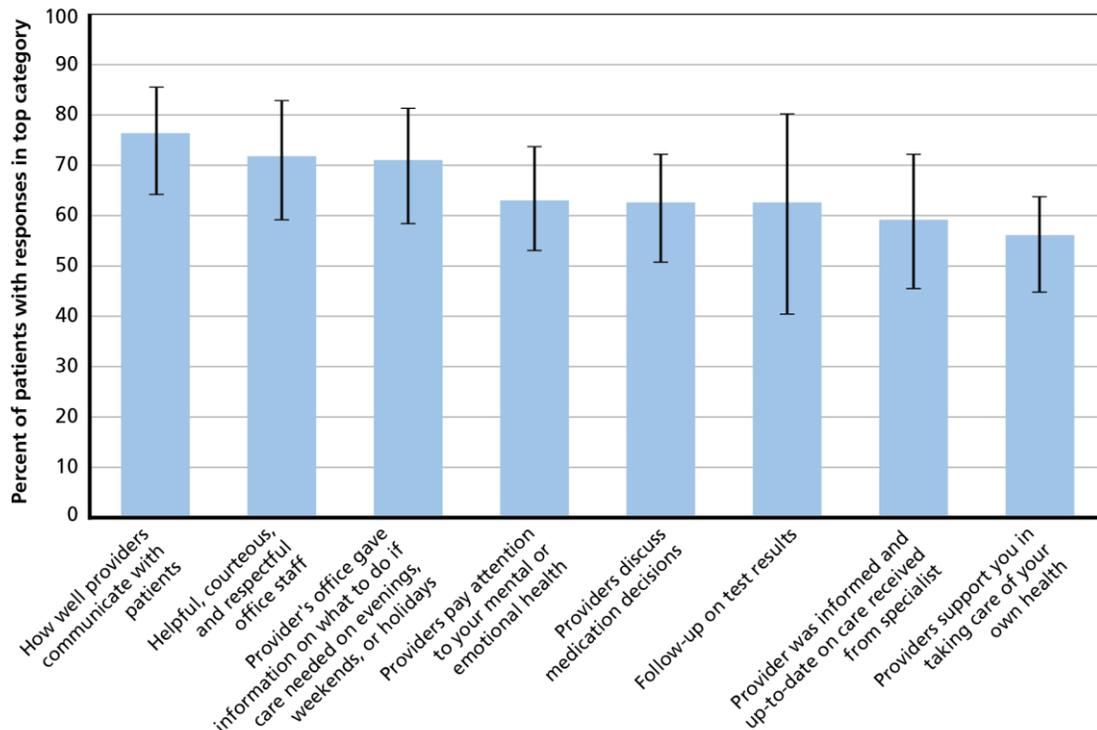
[68] National scores are available for the CAHPS Health Plan Survey and Medicare CAHPS surveys; however, the measures on these surveys are not the same as those on the SHEP PCMH.

[69] We calculated average VA facility Inpatient SHEP measure scores in two ways: (1) using VA's internal patient mix adjustment model and (2) using CMS HCAHPS adjustments. The difference between the two sets of adjusted scores for experience measures, such as communication with doctors and nurses, care transition, and cleanliness and quietness of the hospital environment, ranged from –3.1 to +2.7. The average difference between the two sets of adjusted scores for overall ratings of care was 3.9.

scores and average CAHPS Database scores on reports of care experiences are greater than three percentage points (or differences for overall ratings are greater than four percentage points), they are unlikely to be explained by patient mix alone. Here we consider differences of up to three percentage points between scores of high-performing VA facilities and average CAHPS Database practices as comparable performance, and differences greater than three percentage points to indicate truly higher or lower performance for reports of care experiences; we apply a margin of 4 percent for the overall rating of care.

Taking into account these margins, top-performing VA facilities were comparable to average practices in the CAHPS Database with regard to the proportion of Veterans responding 9 or 10 out of 10 for the overall rating of their health care provider (78 percent for top-performing VA facilities versus 82 percent for CAHPS Database practices), but the 75th percentile of VA facilities performed substantially worse than average CAHPS Database practices on this measure (74 percent versus 82 percent).

Across VA facilities, Veterans responding to the SHEP PCMH at top-performing VA facilities and the 75th percentile of VA facilities were less likely than surveyed patients in CAHPS Database practices to report that their providers always communicated well with them (83 percent for top-performing VA facilities and 80 percent at 75th percentile of VA facilities compared with 92 percent at CAHPS Database practices), that office staff were always helpful, courteous, and respectful (80 percent and 76 percent versus 92 percent), or always followed up on test results (75 percent and 68 percent versus 87 percent).

Figure 5-11. VA Performance on SHEP Patient Experience Measures for Outpatient Setting, FY 2014


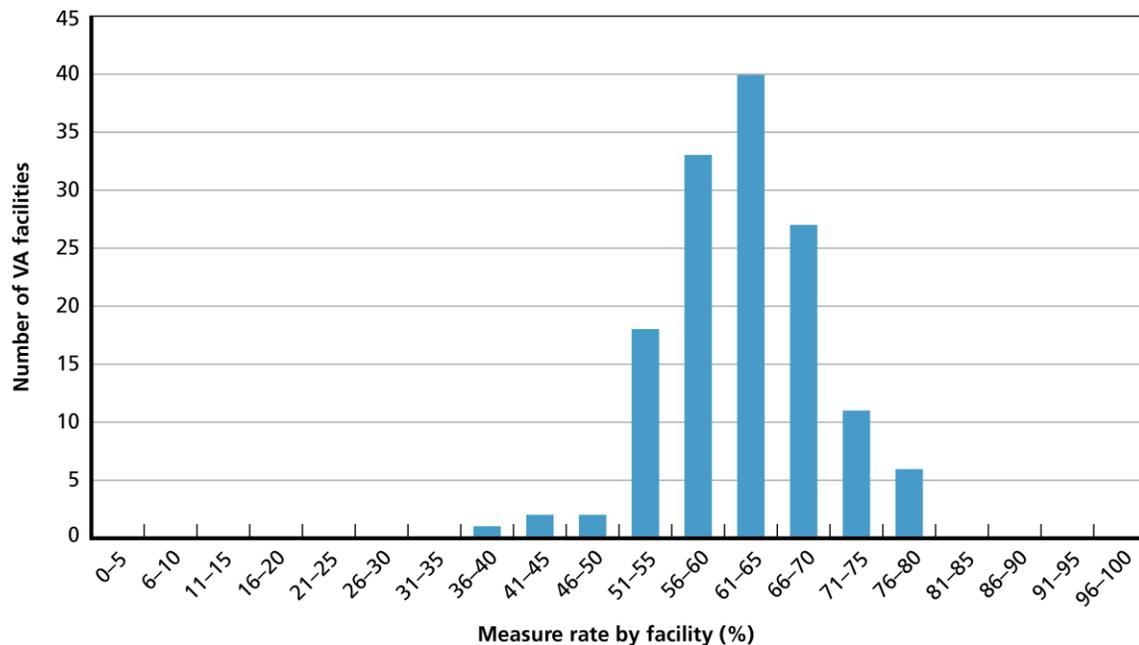
Source: Facility-level outpatient patient experience data for VA patients (SHEP PCMH) in FY 2014 obtained from the VA Office of Performance Measurement.

Notes: How Well Providers Communicate with Patients, Helpful, Courteous and Respectful Office Staff, Providers Pay Attention to Your Mental or Emotional Health, and Providers Support You in Taking Care of Your Own Health are composites that combine more than one survey question. The height of the bar is equal to the mean percentage of patients with responses that fall in the top category. Minimum and maximum values for the reporting facilities for each measure are represented by the line extending from each bar. These national means based on VA facility-level data may differ from national measure rates in VA publications, which are based on patient-level data.

5.2.4 Variation in Current VA Performance

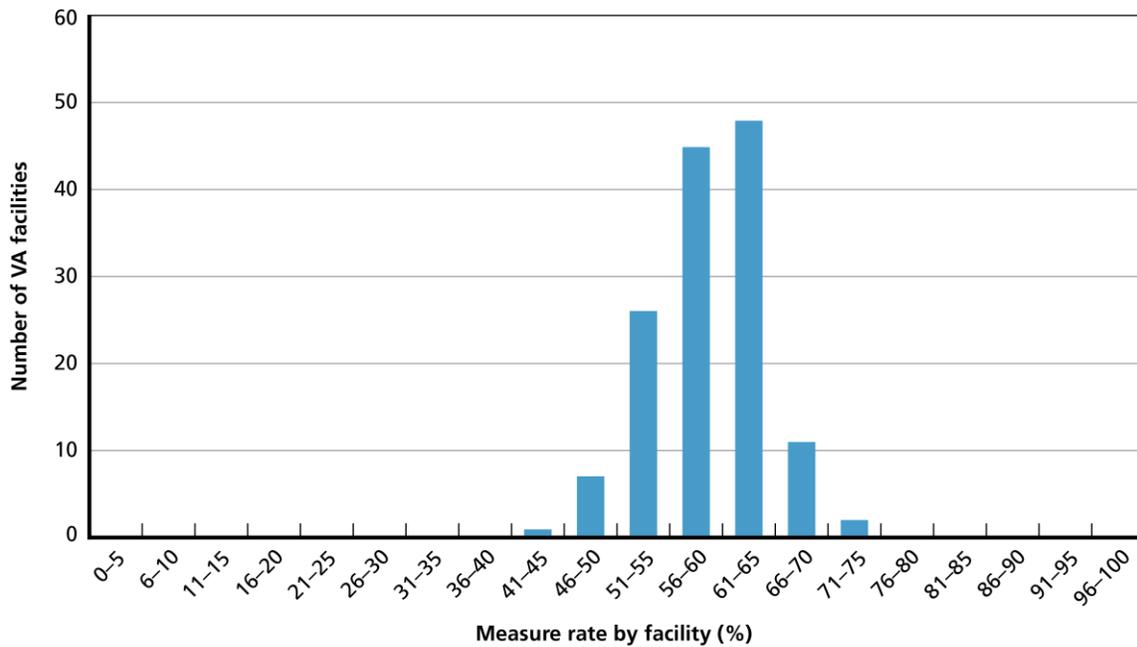
As noted throughout this section, we observed wide variation in performance across VA facilities on many quality measures for the inpatient and outpatient settings. In this subsection, we present four examples, including one related to follow-up on test results with a 40-percentage-point difference between the lowest and highest measure score for VA facilities (Figure 5-12) and another patient experience measure related to care coordination between the providers in the outpatient setting, with a 27-percentage-point difference between the lowest and highest measure score for VA facilities (Figure 5-13). Similar variation was observed for a patient experience measure related to pain management in the inpatient setting (Figure 5-

14), with a 20-percentage-point difference between the lowest and highest measure rate for VA facilities. Another example of a measure exhibiting wide variation across VA facilities is eye exams in the outpatient setting for patients with diabetes (Figure 5-15), exhibiting a 21-percentage-point difference in performance between the lowest and highest measure rates for VA facilities.

Figure 5-12. Patient Experience with Follow-Up on Test Results in Outpatient Setting: Number of VA Facilities by Measure Rate, FY 2014


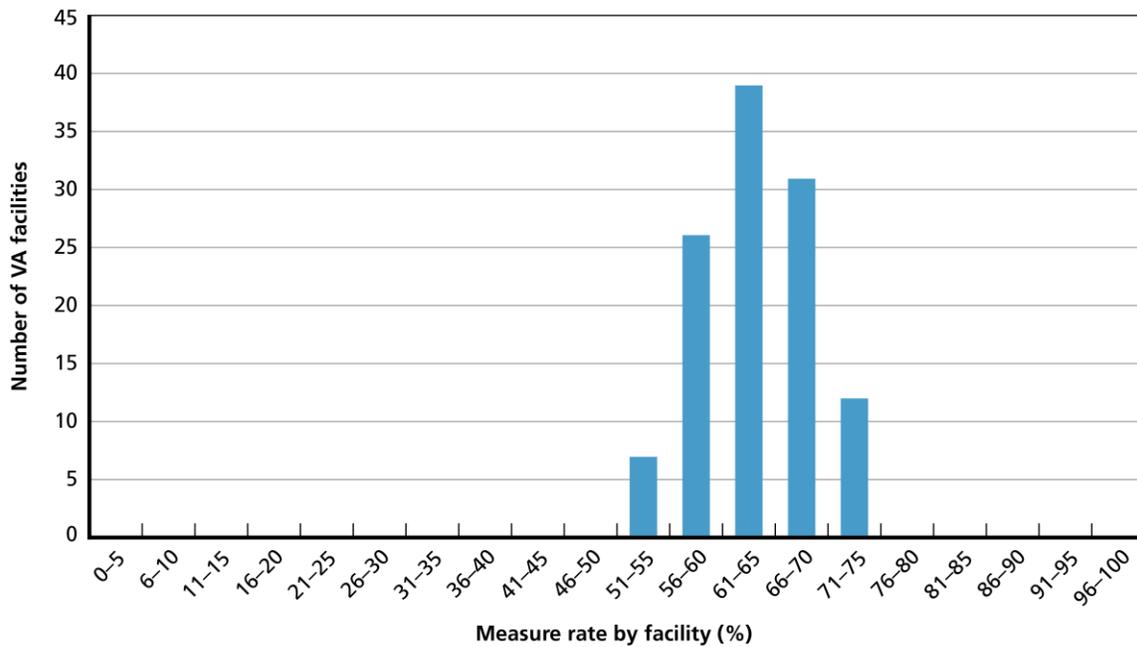
Source: Facility-level outpatient patient experience data for VA patients (SHEP PCMH) in FY 2014 obtained from the VA Office of Performance Measurement.

Notes: The "Measure Rate by Facility" represented on the X-axis is equal to the mean percentage of patients by facility who responded "Always" based on the following responses: "never," "sometimes," "usually," and "always" to the statement: "In the last 12 months, when this provider ordered a blood test, X-ray, or other test for you, how often did someone from this provider's office follow up to give you those results?"

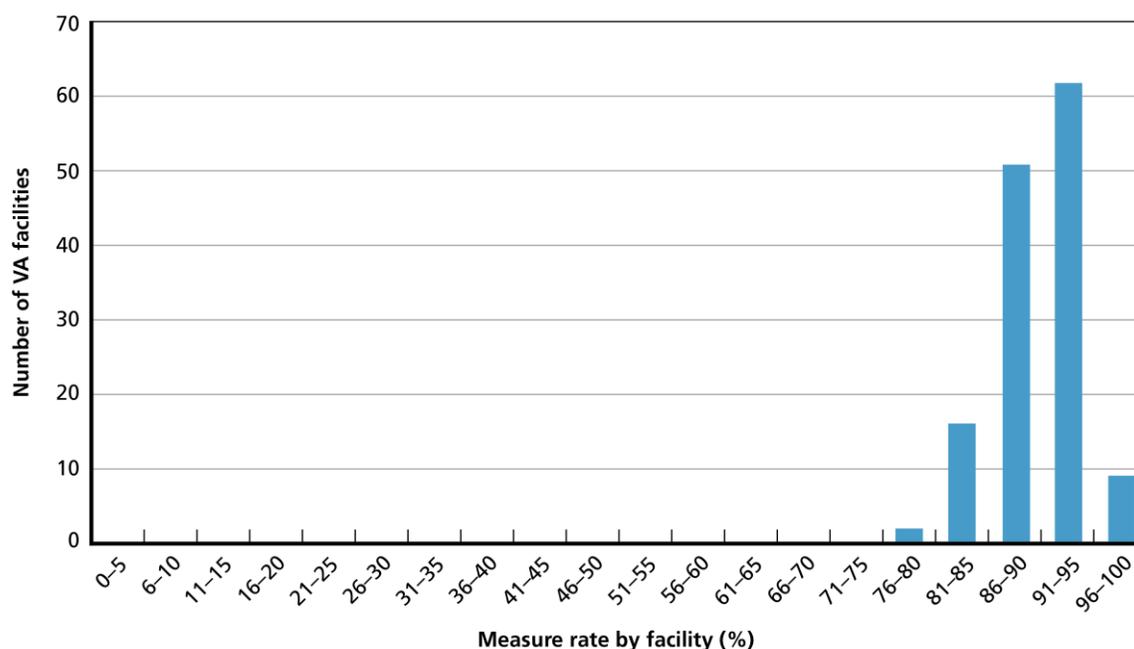
Figure 5-13. Patient Experience with Care Coordination Between Providers in Outpatient Setting: Number of VA Facilities by Measure Rate, FY 2014


Source: Facility-level outpatient patient experience data for VA patients (SHEP-PCMH) in FY 2014 obtained from the VA Office of Performance Measurement.

Notes: The "Measure Rate by Facility" represented on the X-axis is equal to the mean percentage of patients by facility who responded "always" based on the following responses: "never," "sometimes," "usually," and "always" to the statement: "In the last 12 months, how often did the provider named in Question 1 seem informed and up-to-date about the care you got from specialists?"

Figure 5-14. Patient Experience with Pain Management in Inpatient Setting: Number of VA Facilities by Measure Rate, FY 2014


Source: VA facility-level inpatient data for patient experience measures (SHEP) for FY 2014 obtained from the VA Office of Performance Measurement.
Notes: The "Measure Rate by Facility" represented on the X-axis is equal to the mean percentage of patients by facility who responded "Always" based on the following responses: "never," "sometimes," "usually," and "always" to two statements: "During this hospital stay, how often did the hospital staff do everything they could to help you with your pain?" and "During this hospital stay, how often was your pain well controlled?" The measure is calculated as the average of the facility's scores on these two items.

Figure 5-15. Eye Exams in Patients with Diabetes in Outpatient Setting: Number of VA Facilities by Measure Rate, FY 2014


Source: Facility-level outpatient quality measure data for VA patients for FY 2014 obtained from the VA Office of Performance Measurement.

Notes: The "Measure Rate by Facility" represented on the X-axis is equal to the mean value of "Percentage of patients with diabetes who had eye exam (retinal) performed" by facility.

5.2.5   Subsection Summary

We conclude that in many areas of quality of care, the average performance of VA facilities compares favorably with non-VA performance, based on an analysis of measures of quality commonly used by health care organizations for monitoring and quality improvement in inpatient and outpatient settings. However, for some types of measures, our analyses indicated that average VA performance at the facility level is significantly worse than non-VA performance, notably on many of the patient experience measures for care in the inpatient setting and the 30-day all-cause risk-standardized readmission measures for heart attack, heart failure, and pneumonia. Patient experience measures directly evaluate the degree to which care is patient-centered. VA's weaker scores on patient experience measures are indicative of a need for VA to be more responsive to Veterans' preferences, needs, and values.

We also observed substantial variation in quality measure performance across VA facilities, indicating that Veterans in some areas are not receiving the same high-quality care that other VA facilities are able to provide. A high-priority goal for VA leadership should be narrowing these gaps to ensure that quality of care is more uniform across VA facilities so that Veterans can count on high-quality care no matter which facility they access.

5.3   Section Conclusion

Our assessment found that VA health care quality was better on many measures and domains compared with non-VA comparators, while similar or worse on other measures. However, as with access to care, quality performance was uneven across some VA facilities and Veteran subgroups, with many opportunities for improvement.

VA outpatient care outperformed non-VA outpatient care on almost all quality measures. VA hospitals performed the same as or better than non-VA hospitals on most inpatient quality measures, but worse on others. VA performed significantly better, on average, on almost all 16 outpatient measures when compared with commercial, Medicare, and Medicaid HMOs. On average, VA hospitals performed the same or significantly better than non-VA hospitals on 12 inpatient effectiveness measures, all six measures of inpatient safety, and all three inpatient mortality measures, but significantly worse than non-VA hospitals on two effectiveness measures and three readmission measures.

On most measures, Veteran-reported experiences of care in VA hospitals were worse than patient-reported experiences in non-VA hospitals. Average VA facility-level performance was significantly worse than non-VA facilities for six of 10 patient experience measures, including communication with nurses and doctors.

There were mixed opinions on the impact of VA's many quality measures. VA administrators and several health care workers noted that attention to quality measurement has led to improvements in care delivery; however, several respondents felt that measuring quality did not always have a positive effect on how facilities deliver care, and some noted that the current measurement process is a burden for VA providers and other staff members.

The variation in performance across VA facilities suggests that significant opportunities exist to improve access to high-quality care in VA through systematic performance improvement. In the next section, we examine some policy options for improving access to care for Veterans in the future.

6 Improving Access for Veterans

The prior sections focused on VA's current resources and capabilities for providing timely and accessible care. Looking to the future, the size, demographics, and health needs of the Veteran population will change, as described by Assessment A. VA will need to adjust its resources and capabilities to meet the changing demand for services, and this section considers VA's potential response.

VA combines its resources and capabilities to generate the supply of health care services available to enrollees. Access to care, particularly the timeliness of care, is determined in large part by whether the overall level and geographic distribution of supply is well aligned with the demand for VA care. In this section, we compare projected supply to projected demand in FY 2019 under several scenarios and provide insights into potential challenges to ensuring timely access overall and within VISNs. We then assess specific policy options designed to improve access, providing information on the expected impact on access, fiscal considerations, operational feasibility, stakeholder acceptability, and the tradeoffs among them.

6.1 Approaches to Improving Access

VA provides care through two avenues: its own internal resources and capabilities as well as external or private-sector resources and capabilities. Approaches to improving access could focus on either of these two broad categories. Within each category, approaches could focus on modifying the number and/or type of resources available or improving the productivity of existing resources.

Modifying the number and/or type of resources could be accomplished in a number of ways, including expanding treatment space in VA facilities, increasing the number of VA providers, increasing the number of VA support staff (clinical and/or administrative), implementing new IT systems, or making greater use of purchased care. Increasing the productivity of existing resources could also be accomplished in various ways, such as expanding the scope of practice for associate providers, improving coordination of care, and ensuring that physicians can focus on clinical tasks rather than administrative ones. The line between increasing resources and increasing the productivity of existing resources is not a stark one. In fact, many policies include some combination of both. For example, expanding the available treatment space or investing in new IT systems increases VA resources but could also increase the productivity of physicians.

A summary of methods used in these analyses is shown in the box.

Overview of Methods and Data for Analysis of Approaches to Improving Access for Veterans

- To analyze the impact of different approaches on access for Veterans, we projected the amount of health care services supplied under several scenarios and compared these figures to projected demand from VA's EHCPM.
- Under supply scenario one, we forecasted the number of provider FTEs, given historical trends, for each specialty and administrative parent combination. We estimated a time series regression model using FTE data from the VA Productivity Cube for FY 2008 through FY 2014. We then compared the percentage growth in FTEs between FY 2014 and FY 2019 to the percentage growth in projected demand from the EHCPM over the same time period.
- For supply scenarios two and three, we estimated how much additional supply can be created through improved productivity. For supply scenario two, we estimated how much additional supply can be achieved in FY 2019 over realized supply in FY 2014 if low-productivity providers increase their productivity (holding the number of FTEs constant). We created benchmarks that represent realistic productivity levels that could be achieved in the VA system (based on FY 2014 variation in services provided at each administrative parent in each specialty, measured as RVUs per provider FTE). In scenario three, we projected the effect on supply of an increase in the productivity of low-productivity providers in combination with the forecasted change in FTEs.
- For complete details of the methods used to analyze the effect of selected policy options on access, please refer to Section 2 of this report and Appendix A-7.

6.2   Projections of the Impact of Different Approaches to Improving Access

To explore the impact of different approaches to improving timely access to care, we project the supply of VA health care under several scenarios and compare it to projected demand. The supply scenarios reflect the two broad approaches that VA can take.

- **Supply scenario one:** This scenario represents the first approach, which is to increase the number of resources available. The projection accounts for changes in the number of VA physicians (physician clinical FTEs) based on historical trends but assumes no changes in productivity (RVUs per FTE) from FY 2014 to FY 2019. This projection indicates how growth in the supply of VA physicians would need to differ from historical growth rates to meet the demand that EHCPM projects if no other changes affect productivity.

- **Supply scenario two:** This scenario represents the second approach, which is to increase the productivity of existing resources. This projection estimates the effect of productivity changes (increased RVUs per FTE) between FY 2014 and FY 2019 with no changes in the number of resources (physician clinical FTEs).

- **Supply scenario three:** This scenario represents a combination of the two approaches. This projection accounts for changes in both resources (physician clinical FTEs) and productivity (RVUs per FTE).

The demand estimates are measured in RVUs and taken from VA's Enrollee Health Care Projection Model (EHCPM).

As described in Subsection 3.1.1.1, the EHCPM consists of three submodels: the Enrollment Projection Model, the Utilization Projection Model, and the Unit Cost Projection Model (GAO, 2011b; Milliman, Inc., 2014). The demand estimates used in the projection analyses are generated from the enrollment and utilization projection submodels. VA projects total enrollment and then applies VHA-specific utilization rates by service. The utilization rates are created by compiling utilization data from a variety of sources, including VA, Medicare, and commercial claims databases. The utilization rates are then mapped onto physician specialties using RVUs as the measure. We use the demand projections measured in RVUs for our analysis because they provide information at the specialty level, allowing us to compare the supply in a particular specialty to the appropriate expected demand.

The model has some limitations but provides the best available estimates of future demand for VA health care services. Assessment A projects how factors affecting demand, such as the size and composition of the Veteran population and their unique health care needs, will change over time but does not estimate demand itself. Still, the estimates from Assessment A provide useful context for interpreting and assessing the EHCPM demand estimates.

The EHCPM forecasts a 19-percent increase in demand for VA health care services nationally from FY 2014 to FY 2019 (Figure 6-1) due to a projected 5.1-percent increase in enrollment and the aging of enrollees. Although the EHCPM forecast assumes that the number of Veterans will decrease (based on the VetPop model), it projects that a growing proportion of Veterans are enrolling in VA health care (Milliman Inc., 2014) and that the trend is expected to continue through FY 2019. Due to shifts in the demographic composition of the enrollee population, the EHCPM forecasts a 7.6-percent increase in enrollees younger than 45, a 1.2-percent decrease in those 45–65, a 9.0-percent increase in those 65–85, and a 5.8-percent increase in those 85 or older.

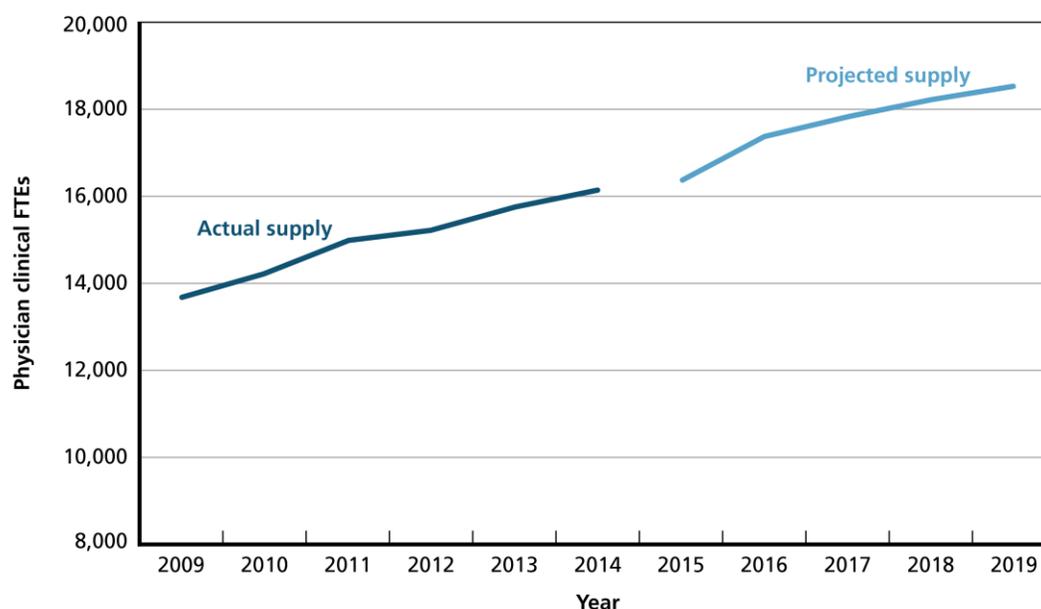
However, the EHCPM estimates of projected demand for VA health care services may be inaccurate. The EHCPM RVU projections for FY 2014 were 5 to 15 percent greater than the actual observed FY 2014 RVUs for most specialties. Moreover, changes in health care options available to Veterans outside VA (through the Affordable Care Act, for example) could reduce enrollment and reliance on VA. Estimates from Assessment A indicate that the number of patients using VA health care services is expected to increase slowly until FY 2019 and then decline. As a result, our analyses of the difference between projected supply and demand could overstate the potential gaps.

Our analysis of projected supply under different scenarios compared with projected demand for VA health care provides a high-level assessment of the likely impact of the two broad approaches to improving access for Veterans. They provide some information about where policy efforts should be targeted (either geographically or in particular physician specialties),

but do not identify which specific policies within these broad categories would be best. We discuss several specific policy options relevant to each approach in Subsections 6.4 and 6.5, incorporating information gleaned from the projections to help refine and target the policy options.

6.2.1 Projected Changes in Supply and Demand Under Supply Scenario One: Increasing the Number of Resources

In this subsection, we compare projected demand and projected supply under scenario one— the effect of changes in the number of resources, as measured by the supply of physicians (physician clinical FTEs). We focus on physician supply because it is a key driver of supply and the only one for which we had access to historical data. We projected physician supply in each specialty through FY 2019 based on trends from FY 2009 to FY 2014. In the model used to make these projections, we limited the change in FTEs to plus or minus 30 percent of the FY 2014 value to prevent the projections from unreasonably exceeding present conditions. The model projects forward the historical trends in FTE growth (see Figure 6-1), though it is important to note that these trends may not persist, as policies and funding change. The median increase from FY 2009 to FY 2014 in FTEs across all specialties and administrative parents was 17 percent. These changes in FTE counts, however, varied by specialty, with thoracic surgery experiencing a median decrease (−1.4 percent) across all administrative parents, and specialties like internal medicine and psychiatry growing substantially (22 percent and 27 percent, respectively). If these historical trends persist, we estimate the national supply of physicians will increase by 15 percent from FY 2014 to FY 2019 (Figure 6-2).

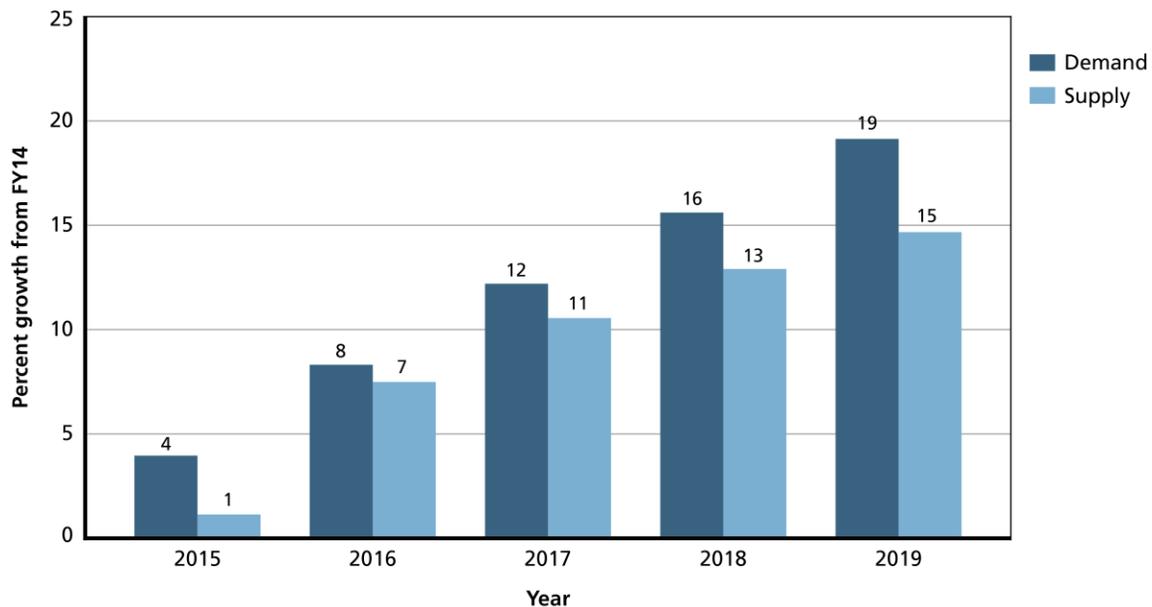
Figure 6-1. Actual Supply FY 2009 to FY 2014 and Projected Supply FY 2015 to FY 2019 of VA Physician Clinical FTEs


Source: RAND analyses of VA provider supply (VA Productivity Cube).

In this scenario, we assume that the quantity of services provided will increase in proportion to the number of physician FTEs. To accomplish this, additional providers would need the same space, equipment, administrative support, and other resources as current VA providers. It also assumes that changes in VA care delivery will not alter productivity. While these assumptions are likely not realistic, together they form a baseline, or status quo, projection.

Under this scenario, the projected increase in demand for services from FY 2014 to FY 2019 (19 percent) is larger than the projected supply of services that VA would produce (15 percent; Figure 6-2) if hiring trends continue. Projected demand exceeds supply for 17 of 21 VISNs, with the difference being much larger for some VISNs than others (Figure 6-3). At one end of the spectrum, the projected difference for four VISNs (VISNs 3, 10, 17, and 18) is more than 10 percentage points. At the other end of the spectrum are seven VISNs (VISNs 2, 8, 12, 15, 19, 21, and 22) with almost no difference (positive or negative difference of 2 or less). This suggests that Veterans' access to timely care will differ depending on where they live and that some will face challenges in getting timely care. However, the difference overall and at the VISN level may be smaller than projected if the EHCPM estimates for the coming years exceed reality, as they did in FY 2014.

Figure 6-2. Projected Growth in Demand and Supply for VA Health Care Services, from FY 2015 to FY 2015-FY 2019



Sources: EHCPM and RAND analyses of VA provider supply.
Note: City hubs associated with each VISN are listed in Table 3.1-3.

Differences between projected growth in demand and supply also vary widely by medical specialty, as shown in Table 6-1. The differences range from positive 6 percentage points (indicating supply growth exceeds demand growth) for infectious disease to negative 36 percentage points for obstetrics and gynecology (indicating demand growth far exceeds supply growth). Most specialties will experience a greater growth in demand than supply if historical hiring trends persist. The exceptions are infectious disease and internal medicine, where the growth in supply is projected to exceed the growth in demand.

Table 6-1. Projected Growth in Demand and Supply for VA Health Care Services, by Specialty, FY 2014 to FY 2019

Specialty	Projected Increase in Demand From FY 2014 to FY 2019 (%)	Projected Increase in Supply From FY 2014 to FY 2019 (%)	Percentage Point Difference Between Projected Growth in Demand and Supply (Supply – Demand)*
Obstetrics and Gynecology	43	8	−36
Plastic Surgery	27	2	−24

Specialty	Projected Increase in Demand From FY 2014 to FY 2019 (%)	Projected Increase in Supply From FY 2014 to FY 2019 (%)	Percentage Point Difference Between Projected Growth in Demand and Supply (Supply – Demand)*
Rheumatology	26	6	−19
Pain Medicine	26	9	−18
Endocrinology	21	3	−18

Cardiology	16	15	−1
Internal Medicine	12	15	3
Infectious Disease	3	9	6

Sources: EHCPM and RAND analyses of VA provider supply.
*Negative value indicates demand is projected to grow more quickly than supply.

Projected differences between the growth in demand and supply also vary widely across VA administrative parents. For example, although the gaps for psychiatry and internal medicine services are small for VA system-wide (−2 and 3 percentage points, respectively), this is not the

case for all administrative parents (Figure 6-4). In both specialties there are many administrative parents in which demand exceeds supply by more than 15 percentage points (the red dots in Figure 6-4). Similarly, we see variation between administrative parents within the specialties where there is a large gap system-wide. For example, system-wide demand growth is projected to exceed supply growth by 18 percentage points for endocrinology, but there are some administrative parents in which supply growth exceeds demand.

This variation indicates that the distribution of projected supply may not match the distribution of increased demand for services in all areas. We note that this observed mismatch may not be entirely VA-specific, but instead may be consistent with broader trends in the health care marketplace (for example, difficulty in recruiting specialists in some geographic areas). Still, the mismatch presages potential access problems for Veterans in some geographic areas.

Figure 6-4. Projected Changes in Demand and Supply for VA Health Care Services, by Administrative Parent and Selected Specialties, FY 2014 to FY 2019

Projected percent growth in supply vs. demand

- ● Supply growth greater by over 15 points
- ● Supply growth greater by 5 to 15 points
- ● Supply and demand growth within 5 points
- ● Demand growth greater by 5 to 15 points
- ● Demand growth greater by over 15 points

Sources: EHCPM and RAND analyses of VA provider supply.

These projections indicate that if the supply of VA providers continues to increase at historical growth rates, and other resources grow in proportion so that providers continue to deliver a similar amount of health care, it will be more difficult for VA to meet the demand for services and provide adequate access. These challenges will be more acute in some regions and at some VA facilities than others, so consideration of distribution will be as important as consideration of overall levels of supply and demand.

6.2.2 Projected Changes in Supply and Demand Under Supply Scenario Two: Increasing Productivity of Existing Resources

For the projection under supply scenario two, we examine the impact of increasing the productivity of existing resources. To do this, we created benchmarks that represent realistic productivity levels that could be achieved in VA's system by analyzing the FY 2014 variation in services at each administrative parent in each specialty (measured as RVUs per provider FTE). We identified the 25th, 50th, and 75th percentiles of the distributions of productivity for each specialty. We then projected FY 2019 supply using the current number of providers (that is, holding physician numbers constant at FY 2014 levels) and increasing productivity of those providers at all administrative parents to at least the level of the 25th, 50th, and 75th percentiles of the FY 2014 distribution:

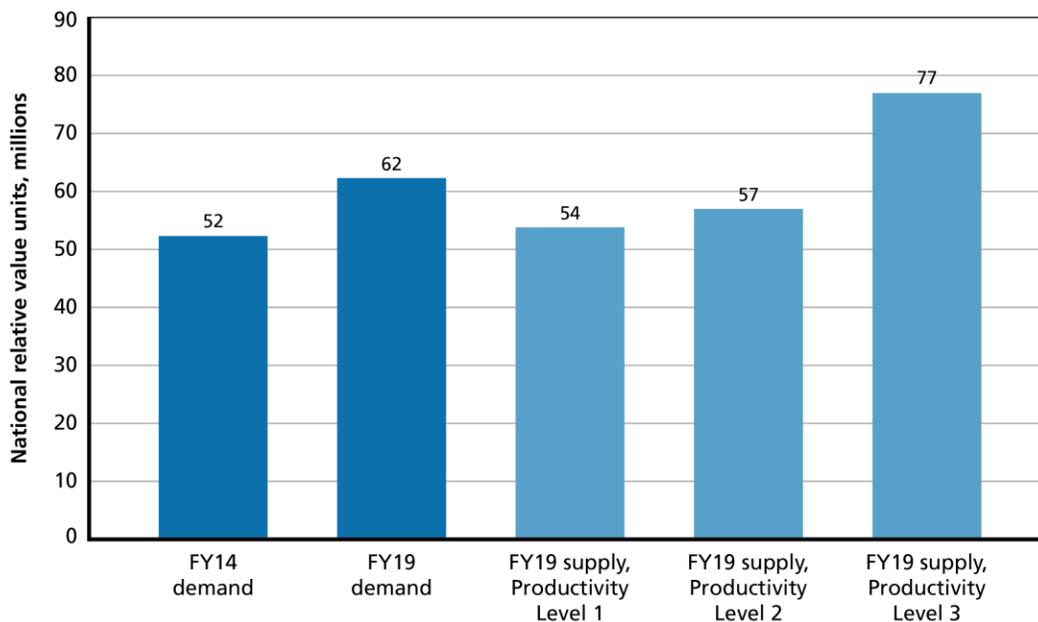
- **Productivity Level 1**: All administrative parents operate at least at the FY 2014 25th productivity percentile within each specialty nationally.

- **Productivity Level 2:** All administrative parents operate at least at the FY 2014 50th productivity percentile within each specialty nationally.

- **Productivity Level 3:** All administrative parents operate at least at the FY 2014 75th productivity percentile within each specialty nationally.

For example, if an administrative parent is operating at the 16th percentile of the productivity distribution nationally within cardiology, the level 1 projection would raise Parent A's productivity to the 25th percentile nationally within cardiology. The productivity of administrative parents that operate above the specified level is left unchanged. This would increase the number of RVUs per provider FTE and generate more RVUs for VA as a whole. This projection provides information on the impact of the productivity changes but not about how those changes are achieved or what resources it would take. Specific policy options for increasing the productivity of resources are described in Subsection 6.4.2.

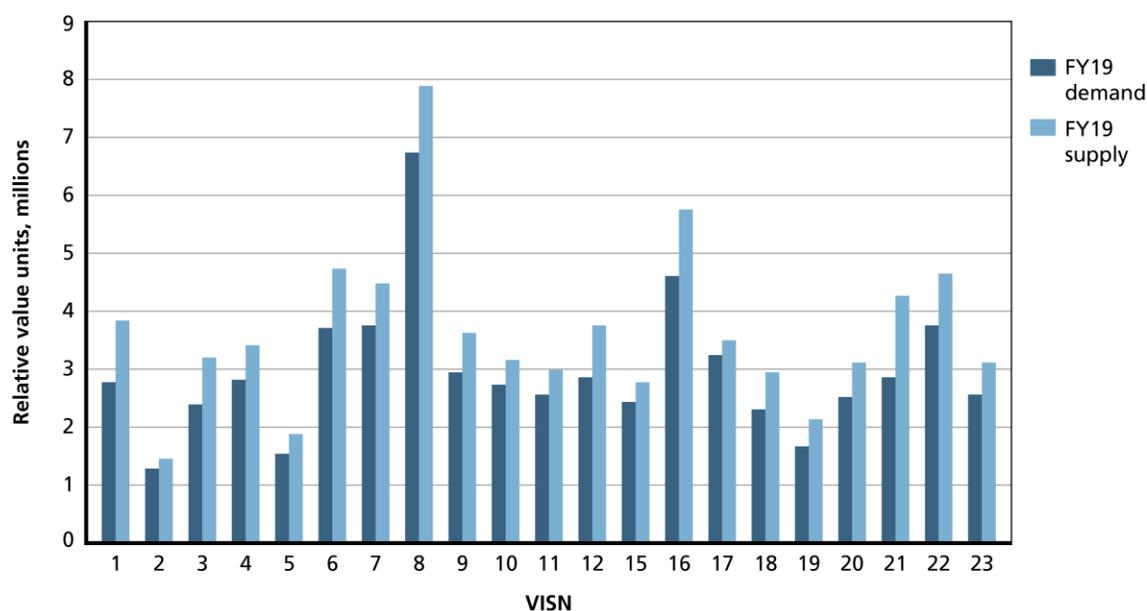
Figure 6-5 shows how VA's production of health care services would be expected to change under this scenario. In FY 2019, EHCPM projects that VA will need to produce 62 million RVUs of health care services. If the number of physicians did not change but productivity per FTE increased, VA in FY 2019 would produce 54 million RVUs of health care services at Productivity Level 1; 57 million at Productivity Level 2; and 77 million at Productivity Level 3. This indicates that, with substantial increases in productivity (every administrative parent operating at least at the 75th percentile of FY 2014 productivity), VA would be able to produce enough health care services to meet projected demand. However, it would likely be quite difficult to raise productivity to the 75th percentile for each specialty in each administrative parent.

Figure 6-5. Projected Demand and Supply for VA Health Care Services Under Scenario Two, Increasing Productivity


Sources: EHCPM and RAND analyses of VA provider supply.

Notes: FY 2019 supply estimates assume that resource levels remain constant at FY 2014 levels. Productivity Level 1 indicates all administrative parent-specialty combinations are at least at the 25th percentile of the FY 2014 productivity distribution. It is 50th percentile and 75th percentile for productivity levels 2 and 3, respectively.

Figure 6-6 shows that raising the productivity of all administrative parents to the 75th percentile of the VA distribution (Productivity Level 3) would generate enough supply in all VISNs to meet projected demand. There is variation in the size of the excess supply, ranging from a low of seven percent in VISN 17 to a high of 48 percent in VISN 21.

Figure 6-6. Projected Demand and Supply for VA Health Care Services by VISN Under Scenario Two, Productivity Level 3


Source: Authors' analysis of VA productivity data and EHCPM demand projections.

Notes: FY 2019 supply estimates assume that physician clinical FTEs remain constant at FY 2014 levels. City hubs associated with each VISN are listed in Table 3.1-3. Productivity Level 3 indicates all administrative parent-specialty combinations are at least at the 75th percentile of the FY 2014 productivity distribution.

There are also some important differences across specialties (Table 6-2). When compared with FY 2019 projected demand, most specialties would not provide enough health care services at Productivity Level 1, would be close to the production needed at Level 2, and would have enough production at Level 3. Demand for health care services is projected to increase relatively slowly for infectious disease, internal medicine, neurological surgery, pain medicine, thoracic surgery, and vascular surgery. In these specialties, improving productivity to Level 1 would bring health care service production to within 10 percent of projected FY 2019 demand.

Table 6-2. Projected Percentage Difference Between VA FY 2019 Demand and Supply, by Productivity Level and Specialty, Under Scenario Two

Specialty	Productivity Level 1	Productivity Level 2	Productivity Level 3
Allergy & immunology	−11	−1	97
Cardiology	−11	−7	21
Chiropracty	−13	−6	44

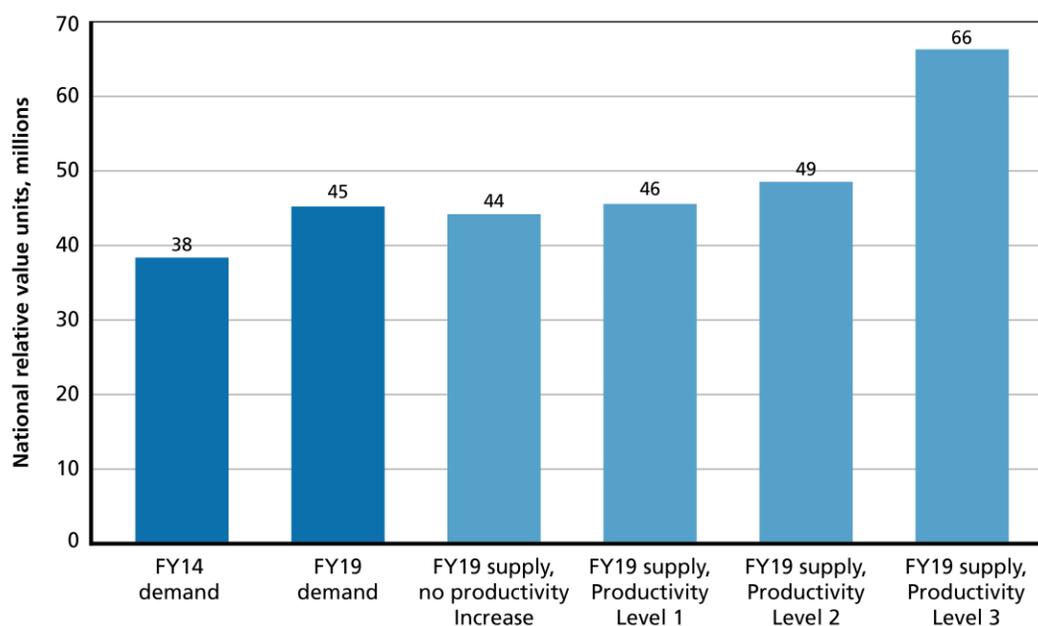
Urology	−14	−5	45
Vascular Surgery	−5	3	59

Source: Authors' analysis of VA productivity data and EHCPM demand projections.
Notes: Negative values indicate that projected supply is less than projected demand in FY 2019. Productivity Level 1 indicates all administrative parent-specialty combinations are at least at the 25th percentile of the FY 2014 productivity distribution. It is 50th percentile and 75th percentile for productivity levels 2 and 3, respectively.

6.2.3 Projected Changes in Supply and Demand Under Supply Scenario Three: Increasing Number and Productivity of Resources

In the third projection scenario, we allow both the number of resources (physician clinical FTEs) and their productivity (RVUs per FTE) to grow, combining the two broad approaches. We project physician clinical FTEs based on historical trends and use the projections for FY 2019 as the base for raising productivity per FTE. In this case, we found that the projected FY 2019 supply at Productivity Level 1 will be somewhat higher than the projected demand (Figure 6-7) indicating that if historical hiring trends persist relatively small increases in productivity would be needed to meet projected demand for VA health care. We should note that the specialty-administrative parent population used in this analysis is a subset of the population used to generate projections under supply scenario two, so the total RVU counts are lower in the analysis for supply scenario three than for scenario two. We use a subset of the population for the scenario three analysis because it uses the FY 2019 FTE forecasts, and missing data precluded generating a FY 2019 FTE forecast for several specialty-administrative parent combinations.[70]

Figure 6-7. Projected Demand and Supply for VA Health Care Services Under Scenario Three, Increasing the Number and Productivity of Resources


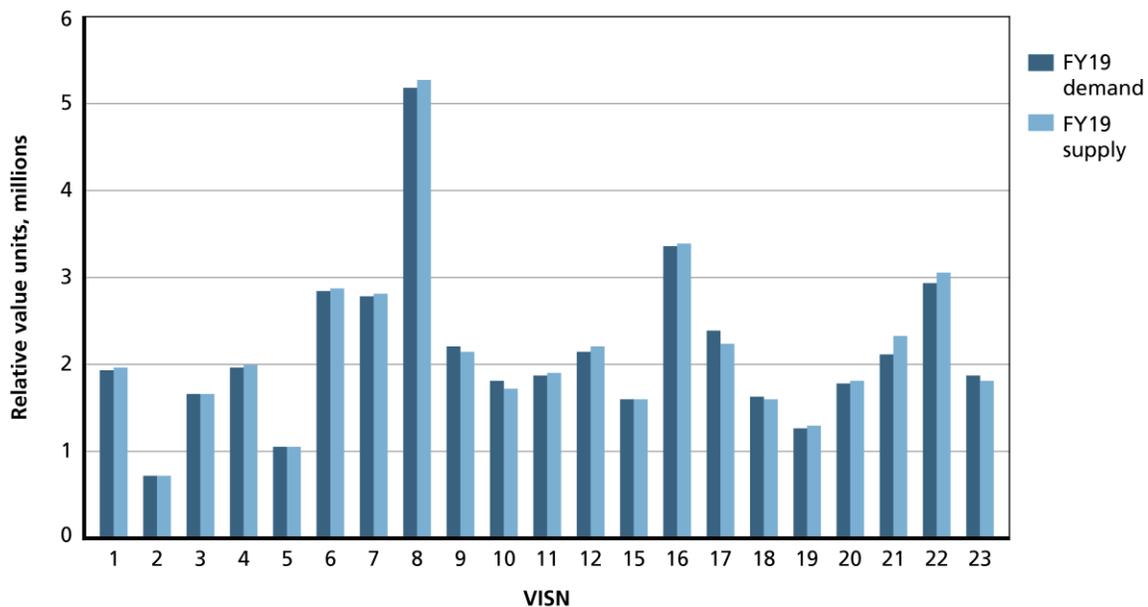
Source: Authors' analysis of VA FTE and productivity data and EHCPM demand projections.
Notes: Productivity Level 1 indicates all administrative parent-specialty combinations are at

---

[70] We excluded specialty-administrative parent combinations where we had less than six years of historical FTE data; we deemed that less than six years of data was inadequate to build a regression model to use for forecasting.

least at the 25th percentile of the FY 2014 productivity distribution. It is 50th percentile and 75th percentile for productivity levels 2 and 3, respectively.

Even though supply exceeds demand at Productivity Level 1 system-wide, there is geographic variation across VISNs in the size of the difference between projected supply and projected demand and whether the difference is positive or negative. At Productivity Level 1, there are seven VISNs (2, 5, 9, 10, 17, 18, and 23) where projected supply is less than projected demand in FY 2019 (Figure 6-8), with differences ranging from 1 to 6 percent. Among the other VISNs, where projected supply exceeds projected demand, the size of the difference ranges from low of less than 1 percent in VISNs 3, 15, and 16 to a high of 11 percent in VISN 21. So, increases in provider FTEs similar to historical trends coupled with modest productivity increases (that is, Productivity Level 1) would be sufficient to meet projected demand in many, but not all, VISNs.

Figure 6-8. Projected Demand and Supply for VA Health Care Services by VISN, Under Scenario Three, Productivity Level 1


Source: Authors' analysis of VA FTE and productivity data and EHCPM demand projections. Notes: City hubs associated with each VISN are listed in Table 3.1-3. Productivity Level 1 indicates all administrative parent-specialty combinations are at least at the 25th percentile of the FY 2014 productivity distribution.

Looking across specialties, we see that at Productivity Level 1, demand would exceed supply for 16 of the 25 specialties considered but by less than 10 percent in most cases (Table 6-3). At Productivity Level 2, obstetrics and gynecology, otolaryngology, and pain medicine are the only specialties for which a gap remains, and the gap is large only for obstetrics and gynecology.

Some specialties considered in the prior analysis are omitted entirely (for example, chiropracty, optometry) from this analysis because we did not have comparable historical FTE data for specialties that do not require a doctor of medicine degree.

Table 6-3. Projected Percentage Difference Between VA FY 2019 Demand and Supply, by Productivity Level and Specialty, Under Scenario Three

Specialty	Productivity Level 1	Productivity Level 2	Productivity Level 3
Allergy & Immunology	53	65	198
Cardiology	2	8	39
Critical Care & Pulmonary Disease	−2	9	66
Dermatology	−8	4	73

Urology	−3	7	68
Vascular Surgery	10	20	84

Source: Authors' analysis of VA FTE and productivity data and EHCPM demand projections.
Notes: Negative values indicate that projected supply is less than projected demand in FY 2019.

Productivity Level 1 indicates all administrative parent-specialty combinations are at least at the 25th percentile of the FY 2014 productivity distribution. It is 50th percentile and 75th percentile for productivity levels 2 and 3, respectively.

6.2.4 Limitations of Projections

These projections have several important limitations. The projections focus on a comparison of demand and supply changes from FY 2014 to FY 2019 but do not account for whether FY 2014 services provided were optimal or sufficient. Similarly, the projections assume that the historical trends that are incorporated will continue into the future and do not consider whether the trends are appropriate from the perspective of optimal patient outcomes.

The projections are based on provider and productivity data (that is, FTEs and RVUs). The projections do not directly include changes in other key resources, such as physical space, equipment, and IT. They do include these resources indirectly through the productivity measure, as increased productivity could come through improved use of these resources. A projection model that included all resources and the interactions between them (for example, system dynamics) would be useful but was beyond the scope of this assessment.

Moreover, the projections analysis is static in that it does not account for changes in demand that might occur if supply, and thus access, were increased. For example, if VA increased productivity of its resources and improved access, current users might increase their reliance on VA and more Veterans might choose to use the VA system. The demand projections we rely on do not account for this demand response, so the comparisons between projected supply and demand may understate a future gap.

Although there is a great deal of uncertainty around these predictions, they provide some evidence that policy changes of some type—increasing either resources or the productivity of resources—will likely be needed to improve access to care for Veterans.

6.2.5 Subsection Summary

VA's EHCPM forecasts a 19-percent increase in demand for VA health care services nationally from FY 2014 to FY 2019. Given the caveats noted above, our projections of supply under three scenarios (increase resources, increase productivity of existing resources, and increase both resources and productivity) indicate that it will be difficult for VA to meet the demand for services and provide adequate access unless they increase both the number and productivity of resources. The challenge of meeting Veteran demand will be more acute in some regions and at some VA facilities than others, so considerations of distribution will be as important as consideration of the overall levels of supply and demand.

6.3 Overview of Selected Policy Options to Improve Access for Veterans

Improvements in timely and accessible care could be accomplished through various policy changes. In the following subsections, we present several policy options to improve VA's ability to provide timely and accessible care to Veterans. These options emerged from an iterative

analytic process involving a review of the published and gray literature, key informant interviews, and ongoing guidance from a panel of in-house advisors. They were further refined based on findings from our quantitative analyses and projections regarding workforce, IT, physical infrastructure, and interorganizational relationships.

A summary of the methods used in these analyses is shown in the box.

Overview of Methods and Data for Developing Policy Options

- We established a framework for identifying potential policy options in consultation with our in-house advisory panel.
- To establish evaluation criteria for assessing policy options, we began with a standard set of evaluation criteria, and then employed an iterative process using data from key informant interviews and a systematic literature review as well as input from our advisory panel.
- To identify a set of potential policy options, we used the options identified through the literature review as a starting point for developing the final list of policy options, and iteratively added, removed, and modified identified options as further information was collected through interviews and advisory panel guidance.
- In finalizing the list of options, we excluded those that (1) were infrequently raised during interviews, or (2) were expected to face significant challenges with respect to at least two of the evaluation criteria.
- For complete details of the methods used to develop policy options, please refer to Section 2 of the report and Appendix A-6.

As described in Subsection 6.1, policy options are characterized according to a two-by-two framework: first, by their primary objective to enhance timely access to care either within VA or outside VA; and second, by the approach to achieving the stated objective, either by modifying the amount and/or type of resources utilized or by increasing the productivity of existing resources (Table 6-4).

Table 6-4. Framework for Selected Policy Options

Policy Objective	Modify Amount and/or Type of Resources	Increase Productivity of Existing Resources
Enhance timely access to care within VA	▪ Increase physician staffing (Subsection 6.4.1.1) ▪ Increase virtual access to care (Subsection 6.4.1.2) ▪ *Increase the number of support staff (Subsection 6.4.1.3)* ▪ *Increase physical space for health care delivery (Subsection 6.4.1.3)* ▪ *Integrate with Department of Defense Military Health System (Subsection 6.4.1.3)*	▪ Formalize full nursing practice authority throughout VA (Subsection 6.4.2.1) ▪ Formalize task assignment in outpatient clinics (Subsection 6.4.2.2) ▪ Standardize return visit intervals for common conditions (Subsection 6.4.2.3) ▪ *Eliminate inappropriate care (Subsection 6.4.2.4)* ▪ *Expand care management programs for complex chronic conditions (Subsection 6.4.2.4)* ▪ *Expand working hours (Subsection 6.4.2.4)*
Enhance timely access to care outside VA	▪ Expand purchased care (Subsection 6.5.1.1) ▪ Shift VA role from provider toward purchaser of health care services (Subsection 6.5.1.2)	▪ Consolidate existing purchased care programs (Subsection 6.5.2.1)

Note: Italicized options were not included for full evaluation.

For each of the identified options, we provide an overview of current practices and issues, rationale for adopting the proposed option, and necessary steps for implementing the option, including any dependencies or requirements salient to its success. We use a traditional policy analysis framework to evaluate selected options against criteria (Patton & Sawicki, 1993):

- Impact on access: Extent to which the policy option is likely to achieve improvements in timely and accessible care
- Fiscal impact: Direct costs and potential savings associated with implementing the policy option
- Stakeholder acceptability: Likelihood of the policy option having sufficient stakeholder support to be politically feasible to legislate or to implement by VA under its existing authority
- Operational feasibility: Ease of putting the policy option into practice.

When possible, we incorporate analytic findings from our assessments of current VA resources and capabilities (presented in Sections 3 through 5) as well as projections to inform our evaluation of the options.

We also provide a brief description of excluded options (italicized in Table 6-4). As described in Section 2 (Subsection 2.8.1), we excluded policy options that were infrequently identified in our

literature review or key informant interviews, or policy options that were anticipated to face significant challenges with respect to multiple evaluative criteria. In addition, some initially identified options were excluded on the basis that they were out of the scope of Assessment B's aim to describe current and projected resources and capabilities of VA. As an example, we did not include or evaluate options that would modify VA's current eligibility structure because they center on modifying demand for health care rather than on modifying existing resources and capabilities to provide care. One such option might be to restrict eligibility for VA health care to only some priority groups, or increase cost-sharing requirements for lower priority groups to incentivize Veterans to seek other health care coverage if available to them.

The options discussed represent a prominent, but not exhaustive, set of options for improving VA's ability to provide timely and accessible care. We acknowledge that there are many alternative approaches. Some of these are addressed by the other assessments, such as reducing inappropriate or unnecessary utilization (Assessment F), optimizing scheduling processes (Assessment E), and improving management and planning for capital assets (Assessment K). In addition, prior evaluations of different aspects of VA care have been conducted and suggest various approaches to improving VA processes pertaining to timely and accessible care. We identified and reviewed these evaluations as part of our literature review, and their findings are reflected in our discussion of the policy options below.

6.4 Selected Policy Options to Enhance Access Within VA

6.4.1 Policy Options to Modify the Amount and/or Type of Resources

As described in Section 3, VA has a range of resources at its disposal to provide access to care but faces certain shortages, sometimes because its resources are not optimally distributed. Below, we describe and evaluate two options that were frequently raised in our interviews and literature review for modifying the amount of key resources in VA to provide timely and accessible care: (1) increase the number of physicians in VA and (2) increase virtual access to care through telehealth expansion. Other options that we considered but did not select for evaluation include increasing the number of support staff, increasing physical space for health care delivery, and integrating with the DoD military health system.

6.4.1.1 Increase Physician Staffing

6.4.1.1.1 Overview

This option would increase the number of VA physicians to expand the number of patients who can be seen in a timely manner. We focus on physicians rather than nurse practitioners, physician assistants, or other prescribing providers because physicians are currently the only providers able to practice with full and unambiguous independent authority consistently throughout VA. Other providers are more likely to serve in supplementary roles that have the potential to augment physician productivity. (In Subsection 6.4.2, we discuss two options for augmenting physician productivity through the use of existing staff and providers: formalizing task assignment in outpatient clinics and formalizing full nursing practice authority.)

6.4.1.1.2   Rationale

Data from multiple sources suggest that VA will need to increase its specialty physician workforce in the next five years (see Subsection 6.1, Figure 6-1) to meet growing demand. Using historical trends, our forecasts predict that by FY 2019, RVUs will exceed FTEs by at least 15 percent for obstetrics and gynecology, plastic surgery, rheumatology, pain medicine, endocrinology, otolaryngology, dermatology, and neurology (Table 6-1). In addition, the workforce analyses described in Subsection 3.2.3 identified several subspecialties that currently have longer appointment wait times than others, potentially indicating insufficient capabilities. These subspecialties include neurological surgery, neurology, gastroenterology, and physical medicine and rehabilitation.

VA primary care also faces potential workforce shortages. Primary care is one of five challenging areas for retaining and recruiting physicians and for which demand is growing, according to the 2014 VA Interim Workforce and Succession Strategic Plan. (The other challenging areas are gastroenterology, psychiatry, cardiology, and orthopedic surgery). In VA primary care, appointments have increased by 50 percent over the past three years while VA's primary care physician workforce has increased by just 9 percent (Oppel Jr. & Goodnough, 2014).

Physician workforce shortages were consistently identified in key informant interviews as an important constraint on access, and these interview data echoed some of our analytic findings. For example, interviewees cited neurology, which had substantial wait times in our analysis (Subsection 3.2.3), as a specialty with current or expected workforce shortages. Responses to our 2015 Survey of VA Resources and Capabilities supported our interview findings and the results from our wait-time analysis, with neurology, gastroenterology, and physical medicine and rehabilitation as key specialties survey respondents identified as having current or expected workforce shortages.

Interviewees highlighted several challenges pertaining to physician workforce shortages, including the organization's ability to attract competitive candidates, especially for specialty positions where VA salaries are not on par with the market and a slow and burdensome hiring process. Results from the Chief of Staff module of our 2015 Survey of VA Resources and Capabilities show that 98 percent of administrative parents reported difficulty recruiting or hiring inpatient physicians such as hospitalists and intensivists, and 62 percent reported difficulty recruiting or hiring subspecialists such as dermatologists, with noncompetitive wages being the primary reason (geographic location and sluggish HR processes were also reported as contributing to recruiting and hiring challenges). Dissatisfaction with pay was also reported as a key reason for problems with retaining specialist physicians.

Increasing the number of physicians and other licensed independent practitioners was viewed as a critical or very important way to reduce clinically meaningful delays in patient care by approximately 94 percent of sites (46 of 51 sites) reporting patient delays in obtaining a new primary care appointment on the 2015 Survey of VA Resources and Capabilities.

Assessment G explores the various gaps and challenges in VA workforce staffing as well as approaches to addressing these challenges in further detail.

6.4.1.1.3 Implementing Steps

Increasing the number of physicians in VA might involve several strategies. The first is simply increasing funding so facilities can hire more physicians. This might focus on the service lines with the greatest hiring needs as identified by our wait-time analysis and interviews.

Targeted physician hiring focused on specialties with the largest staffing shortages can be a sustainable approach to implementing this option, and Section 301 of the Veterans Choice Act mandates that the VA Inspector General annually identify the five occupations with the largest staffing shortages over the prior five years. However, it should be noted that although the Veterans Choice Act provides $5 billion in additional funding to hire new clinicians (in addition to improving physical infrastructure), hiring has been challenging. While VA has set an interim goal of hiring 10,682 clinicians by September 30, 2016, using $2.2 billion in Veterans Choice Act funding, recent reports (Robeznieks, 2015) suggest that VA had hired just 2,600 new clinicians as of May 2015, or 25 percent of the interim goal. This suggests that funding for new positions addresses only part of VA's challenge. Another strategy could be adjusting physician salaries (for example, based on productivity) to support retention or raising salaries of VA physicians to market rates to attract new hires. The latter might entail raising current salary limits for specialty physicians in geographic areas where recruitment is a particular challenge (for example, rural areas or areas with strong market competition). Data described in Section 3 (Table 3.2-13) show that VA salaries for many specialty services are well below private practice averages and generally lower than academic medical center practice as well.

VA could also increase its use of incentives such as relocation bonuses in rural areas, loan forgiveness, affiliate faculty appointments, and protected research time. Interviewees commonly cited the inability of facilities to offer benefits such as debt reduction plans as a challenge to physician retention in areas where salaries differed significantly between proximate geographic regions. Some interviewees identified the lag time in calculating VERA funding allocations to VISNs described in Subsection 3.1.2.3 as a challenge in determining the appropriate funding allocation for recruiting and retaining new providers that may need to be addressed in future efforts to improve VA's hiring process.

Another strategy might be to streamline the hiring and credentialing process so new physicians can start work sooner. Many interviewees noted it can take upward of six months to recruit and hire a provider, and a lengthy credentialing process might further delay the physician's start date. Facilities report losing interested and qualified applicants—and even accepted candidates—to private-sector jobs with more timely hiring processes and start dates. Indeed, testimony from VA physician and nursing association representatives to the House Veterans Affairs Committee's Health Subcommittee indicated that, despite the Veterans Choice Act's cash infusion, the "slow and bureaucratic" hiring process has hindered the organization from reaching its hiring goals. Interviewees identified the need for standardized credentialing processes as well as faster processing of paperwork and other requirements such as fingerprinting and physical exams that are not usually required for private-sector positions. Streamlining the hiring process by waiving requirements where possible, processing paperwork faster, or standardizing training and credentialing within a single system will likely allow VA to attract and retain more physicians. Assessment G characterizes this issue in detail.

Critical to the success of this option will be the availability of additional office space, exam rooms, and equipment for any newly hired providers to actually practice and see patients. Interviewees remarked that even if a department were able to retain a new hire, no office or other suitable workspace was available once the provider's state date arrived. In addition, clinical and administrative support staff will be needed to support the workflow and clinical processes associated with the increase in licensed independent providers.

Finally, this option should be targeted toward geographic areas and specialties with demonstrated physician shortages (primary or specialist); otherwise, existing workforce inequities might worsen. Resources could be targeted toward VISNs (for example, VISNs 3, 5, 10, and 17) where the projected growth in demand for health care outstrips the projected growth in supply, as described in Figure 6-2. Similarly, increased hiring might be particularly salient for specialties such as obstetrics and gynecology, rheumatology, and endocrinology, as shown in Table 6-1.

6.4.1.1.4 Evaluation

Impact on access. Increasing the number of physicians in VA may improve VA's ability to provide timely and accessible care by increasing the availability of clinicians to see patients, but it is highly dependent on having adequate administrative and clinic space for new providers to work in, and adequate administrative and clinical support staff to manage the workflow processes associated with additional clinic appointments (for example, checking patients in, turning over exam rooms between patients, collecting basic patient information in preparation of the visit, etc.). Both factors—space and support staffing—are already critical challenges for VA, limiting the potential impact of this option on access. Interviewees frequently cited a lack of space to house new staff and to manage the additional capacity created by increased hiring as a major frustration and a limitation to the potential of increased hiring. In addition, the impact will be constrained by local market characteristics and the employment availability of potential workers in a given geographic area, with rural areas being the most acutely impacted. These areas may not benefit from increased hiring alone. It is possible that increasing hiring of physicians across the board may adversely impact rural areas where recruitment and retention is particularly difficult by exacerbating existing inequities.

Costs. This is likely to be an expensive option to implement, as it requires funding more open positions for physicians, increasing salaries, providing other financial incentives, or some combination of these. In addition, applying funds to the hiring process in a timely manner will likely be challenging; VA interviewees often remarked on how difficult it has been to actually use the funds allocated by the Veterans Choice Act to hire new providers. Furthermore, this option would require costly expansions to physical infrastructure to support the additional clinical activities associated with more providers.

Stakeholder acceptability. Prospects regarding stakeholder acceptability are uncertain. Hiring more physicians may be an attractive strategy to the public and Veterans, given recent attention to provider shortages both within and outside VA. Interviews with Veterans Service Organizations suggest that improving access to VA physicians simply by increasing their numbers is a popular alternative to outsourcing care to private-sector physicians. However, the

costs associated with this option as well as the funding already put toward increased hiring through the Veterans Choice Act may detract from its political feasibility at both organizational and legislative levels. In addition, there may be concerns regarding the impact this option might have on private-sector capacity if it draws physicians away from the civilian health system and into VA. As with the impact on access, this is particularly salient in underserved or rural areas where physicians are often in short supply.

Operational feasibility. There are significant administrative barriers to increasing the number of VA physicians. Hiring within VA is complex, requiring a mix of administrative tasks (for example, creating and approving the position description, opening the position to all applicants on USAJobs, ensuring an equitable evaluation process, conducting background checks and fingerprinting) and clinical tasks (for example, verifying clinical credentials, licenses, certifications). Reducing the time to start date in VA poses an additional administrative challenge. Streamlining these tasks and consolidating the number of departments involved in the process is likely to prove challenging and time-consuming. In addition, VA may ultimately be limited by Office of Personnel Management rules guiding the organization's hiring processes and practices.

Summary statement. Adding more physicians to VA's workforce is a potentially impactful approach to improving VA's ability to deliver timely and accessible care, but its short-term impact on access is significantly constrained by the high costs of hiring more physicians, the lack of infrastructure to support an expanded workforce, and the bureaucratic challenges related to hiring in VA.

6.4.1.2   Expand Virtual Access

6.4.1.2.1   Overview

This option would expand VA's use of clinical video telehealth to increase access to clinical care when distance separates the patient and provider. As described in Section 3, VA might consider developing standardized protocols for telehealth workload capture and attribution, medical record documentation by remote providers, and provider credentialing for telehealth. It might also consider implementing a single system-wide memorandum of understanding allowing service delivery between sites.

6.4.1.2.2   Rationale

As discussed in Section 3, VA is the largest provider of telehealth services in the United States and has been a trailblazer in implementing clinical video telehealth and related telehealth technologies (Mazmanian, 2014). Data suggest that there is room for VA to build on its leadership role and further leverage clinical video telehealth to increase Veterans' access to care. For example, in FY 2014 more than 3.5 million encounters occurred in VA with a psychiatrist (authors' analysis of VISTA New Person File, VISTA Patient Care file, and Monthly Program Cost Reports provided by Assessment G), but just 104,632 mental health encounters (including but not limited to psychiatrist encounters) were conducted via clinical video telehealth (Table 3.5-1). This suggests an opportunity to expand clinical video telehealth use for

---

262

mental health care—an approach mentioned by many VA interviewees. Moreover, interviews revealed that clinical video telehealth mostly involves just a few types of encounters (for example, mental health, weight management, clinical pharmacy, and primary care), indicating considerable room for expansion and diversification. Some interviewees stated that, given the foundation and infrastructure that VA has already established, telehealth use could potentially expand to almost all services lines and almost all types of care.

6.4.1.2.3   Implementing Steps

Despite VA's established telehealth infrastructure, access to care via telehealth has been limited due to several issues highlighted by our interviewees and echoed in the literature. These barriers, described in detail in Section 3, include poor recruitment and retention of telehealth staff, few available providers willing to use telehealth technologies, insufficient space for telehealth (Alverson et al., 2004), absence of standardized protocols for credentialing clinicians across facilities and capturing and attributing workload, inadequate technical support, and complex and burdensome security requirements (Adle et al., 2001; Darkins et al., 2008). Implementing this policy option will primarily require additional staff, equipment, and network capacity (Alverson et al., 2004) to support telehealth expansion and address the challenges described.

To address some of these issues, VA could establish standardized protocols for telehealth workload capture and attribution, medical record documentation by remote providers, and provider credentialing for telehealth. Implementing a single system-wide memorandum of understanding allowing service delivery between sites might also be a consideration. In addition, it will be critical for Central Office, VISN, and facility leadership to support telehealth expansion by encouraging its integration into routine service provision, providing time and training opportunities for providers, and allocating more resources. Some of those goals might be achieved through the use of targets and incentives. For example, target utilization rates could be set for different modalities, or providers could receive financial inducements, similar to VA's new "workload credits" that credit providers for the time they spend exchanging messages with patients or performing electronic consults.

6.4.1.2.4   Evaluation

Impact on access. Expansion of telehealth in VA is likely to enable timely access to care (Agha et al., 2009; Wakefield et al., 2004; Whited et al., 2002; Whited et al., 2004; Wilkins, Lowery, & Goldfarb, 2007) in several different ways. Clinical video telehealth can facilitate contact between distant patients and providers and is particularly useful for patients in rural or otherwise underserved areas who face transportation barriers, poverty, and limited access to specialty care (Luptak et al., 2010). For example, one study conducted at five VAMCs and their associated CBOCs across eight states examined the use of clinical video telehealth to increase access to psychotherapy for Veterans with PTSD by connecting patients at the CBOCs to a dedicated mental health clinician at the associated VAMC. Study investigators found that the five participating sites averaged a threefold increase in unique patients seen and a 6.5-fold increase in psychotherapy sessions via video telehealth over a 21-month period compared with

the baseline; meanwhile, nonparticipating sites across the same region averaged increases of just 1.4-fold and 1.7-fold, respectively (Lindsay et al., 2015).

As discussed earlier, for some specialties VA could meet the projected demand without additional hiring if the demand could be better distributed within the existing workforce. Clinical video telehealth may be a promising mechanism for achieving this redistribution for some specialties. Psychiatry, psychology, and dermatology are particularly good candidates for clinical video telehealth from a technical standpoint, given that many visits that do not require physical touch or procedures.
